"ALIUŠ" quotes the "renowned American Root" as recommending zinc vessels for honey, and is severe upon such teaching. The first honey he ever extracted he allowed to stand over night in a zinc (galvanized iron) extractor, in a damp kitchen, and next day the surface of the honey for an inch in depth was thin, black as ink, and tasted abominably. Three-fourths of it had to be thrown away.—*Ill. Monatsb.*, 68, [We do not know where Alius got the impression that we recommend zinc or galvanized iron unqualifiedly for the storage of honey. We do know this: that galvanized iron is used very extensively by the California beekeepers in their mammoth storage tanks, which are large enough to hold from ten to twenty tons of honey. In these large tanks the exposure of the zinc to the honey is relatively small. We use galvanized iron and tin in our honey-extractors because it is not supposed that the honey is to be kept stored in such machines. The honey-gate should be left wide open always, so that the honey can run into some other container. We admit that, if an inch or so of honey were left standing in the bottom of a galvanized-iron extracting can for a considerable length of time, the honey might absorb enough of the zinc so it could be tasted. Whether it would be poisonous or not we have our doubts. If "Alius" will point out the place, either in GLEANINGS or in the A B C and X Y Z of Bee Culture, where we distinctly recommend galvanized iron for making up honey-storage tanks we shall be glad to have him do so. The fact is, our literature is supposed to show what is being used for the storage of honey with perfect safety. Some of our foreign readers, probably from their inability to understand properly our language, appear to misread and therefore misquote.—Ed.]

NOTES FROM CANADA

J. L. BYER, Mt. Joy, Ont.

That cover picture of the June 1st issue reminds me that, for some reason, raspberries here in Ontario do not yield honey to the same extent as reported in northern Michigan. While the raspberry is a good honey plant, yet it does not last very long; and as soon as clover comes into bloom the bees prefer the latter. By the way, I was talking to a friend a few weeks ago who formerly kept bees in northern Michigan, and in his opinion much of the "raspberry" honey of that section comes from milkweed and white clover. This claim is given without any comment on my part, as I know nothing personally about the matter. [The milkweed honey has quite a different flavor from the raspberry, as does also the white clover.—Ed.]

* * *

The editorial, page 327, June 1, regarding five-banded bees, is quite in order—not that I would pick out the advertisers of these bees for special criticism, but, rather, that we should insist on more careful advertising without the exaggeration so common to many who make claims for their goods in the press of the country. About the worst sinners in this respect are some of the advertisers in the poultry journals, and sometimes these same advertisers do not confine their efforts to poultry journals, but branch out in the bee journals. A person who answers an advertisement with hard cash has a right to receive just what the advertisement leads him to believe he will receive. Any thing less than that is fraud; and the writer of the advertisement, if he willfully misrepresents his goods, is, in plain English, a *liar* as well as a fraud.

* * *

An unusual number of demonstrations have been carried on in different Ontario apiaries this spring, and in most cases they have been well attended whenever weather was favorable. During the last week in May I was at two of these meetings in Hastings Co., and both were well attended, even though rain poured steadily all the time on the last day. While we could not open hives, yet we used empty hives and appliances for object lessons, and worked inside a building. As there were 20 or more beginners present on such a bad day, we wondered how many would have been there if the day had been fine. There is a source of pleasure in talking to a large number of

enthusiastic beginners in a meeting of this kind, and almost unconsciously the demonstrator will try to give the very best that is in him, when an audience is so appreciative. While I have little time for work of this nature, I unhesitatingly plead guilty to having a liking for it aside from what little pecuniary recompense there is in the job. I well remember how I used to like to find out things about beekeeping (the desire is still present) and now it is always a source of pleasure to meet some youngster who is enthusiastic about bees, and any help that I can give him is always given with great pleasure.

* * *

Last year at this time (June 12) the weather was hot and the ground dry and hard. This year we had cool weather all through May with the exception of two hot days (23d and 24th), and June up to date has been much the same, with the exception of last week, when no rain has fallen. The season is very late, as only a few clover heads are showing; and any flow, if we should have one, can not possibly be on before June 25, at the earliest. Clover is good wherever there is any; basswood is showing lots of buds, and there will be more than the usual acreage of buckwheat in many sections where the wet weather prevented seeding with other grain. This will not be in evidence in our locality so much, as most of our land is tile-drained, and the wet weather did not hamper the farmers so much. However, we look for quite an acreage of buckwheat on account of many farmers sowing their summer fallows with this plant in an effort to kill many of the weeds which seem to be on the increase of late years. At the east yard, the blueweed is in evidence as usual, and the prospects are good for basswood, of which there is an abundance in that section. Up north 100 miles, where I have one apiary, the prospects are good for all the usual sources of nectar—especially so for alsike and white clover.

While we have mentioned more than once that the prospects are poor at the home yards here in York Co., with good strong colonies we may perhaps get some surplus after all. At any rate, before the next batch of copy comes for GLEANINGS the question will have been decided one way or the other.

Beekeeping Among the Rockies

WESLEY FOSTER, Boulder, Colo.

The beemen of Fremont County have an energetic inspector in Mr. Flo. Brainard. Mr. Brainard inspected over 100 apiaries in 1911, containing about 1000 colonies. The foul-brood situation looks much better than last year, and within a short time it is probable that the loss will be reduced to the minimum. Mr. Brainard operates about 200 colonies of bees, and has a 7½-acre fruit place. He sells the most of his honey and fruit in the Cripple Creek mining country, and gets a better price than most Colorado beemen.

* * *

A good many bees have been killed by the fruitmen in the Canon City fruit districts by spraying with arsenate of lead for the leaf-roller. Probably some colonies will be depleted in strength, but few killed completely. The leaf-roller is a very serious pest, and the fruitmen feel that spraying is the only way to save their orchards from total destruction. They admit, however, that the spray is killing only a few of the rollers, but as long as they kill a few, some will continue to spray. Not all spray when the trees reach full bloom, although I saw two orchards in bloom being sprayed. Very few fruitmen now spray for codling moth at a time when the bees can be injured.

* * *

May 10 sweet clover was up one foot at Canon City, and colonies averaged four to six frames of brood. Freezing weather had hardly passed either. Canon City is further along with the season than any other part of the State. It is the distributing point for spring weather in Colorado. And there is one thing I want to say about this Canon City district. It is the most highly developed rural section of the State—perfect roads, rural delivery, tidy, comfortable homes (the houses are not oversize, as is so common in many rural communities), rural phones, small fruit-farms that are not a burden in caring for them. The climate is Californian with the rainy season left out. Canon City is a rural town; the town folks are the same as the country folks, and I'll dare any one to tell where the city limits of Canon City are. The town and country are one, and blend into each other imperceptibly. The town folks have the country spirit, and the country folks have the city advantages. I am often told that Boulder is the prettiest town in Colorado. If Boulder had the fruit district of Canon City surrounding it, my home town would be the best place on earth.

WINTER LOSSES AND HONEY PROSPECTS.

Bees have not wintered very satisfactorily, and in a number of places spring dwindling is depleting the colonies. The losses amount to about 25 per cent in the Platte Valley from Denver to Sterling. Some reports give a loss of 50 per cent near Sterling. While I have no report on the percentage of loss in the Arkansas Valley, word has come to me that bees did not winter well in that section. Several Wyoming beemen have written to me wanting to buy bees, and one gentleman said his losses had been heavy. From the low temperature recorded last winter in Wyoming, and the fact that most of the bees are kept in single-walled hives, heavy losses would naturally be expected. Some Idaho beemen are after more bees, partly due to loss of colonies and partly to a desire on the part of some to expand their operations. Idaho suffers as does Colorado, and doubtless other States, from overstocking in one locality and a lack of colonies in another. I can not say whether Utah beemen have suffered any losses or not, as I have no reports; but parts of the western slope of Colorado have had heavy losses, the largest loss being Montrose, where the mortality in a few apiaries was 50 per cent with many weak colonies trying hard to survive during the month of May.

I am writing this May 12, and the Montrose men say that two or three frames of brood are about as much as can be found at this time. Some hives have more and some less. It should be said here that the season is at least three weeks late, and there is still hope; but the backward season is playing "hob" with the weak "uns."

Now, in my judgment the prospects are good, there is an abundance of water for irrigation, and sweet clover is coming up as well as if not better than usual. This does not seem to be the case near Denver, but is true everywhere else that I have observed. The price of hay (alfalfa) is now \$18.00 to \$20.00, and at such a price the farmers will not leave the first cutting till it can bloom.

The fruit bloom is coming out in a gratifying manner, and a great fruit yield is expected if no freezing occurs. The fruit bloom is of considerable importance to the bee interests where it abounds, and stimulation to breeding and early swarming is the result. It seems here in the West that the swarming problem is a *problem* only in the regions of fruit bloom.

BEEKEEPING IN CALIFORNIA

P. C. CHADWICK, Redlands, Cal.

In seven days after the sage weevil got fairly started, the sage was out of commission, with thousands upon thousands of buds destroyed that never matured.

* * *

GIVE PROF. COOK TIME TO MAKE GOOD.

From items that have appeared in various California publications it seems that State Horticultural Commissioner Cook, whom we know familiarly as Prof. Cook, has caused a storm of protest, some of which might be termed almost mild abuse, by summarily removing Chief Deputy Quarantine Officer E. O. Brenner. Mr. Brenner apparently had the confidence of fruit men over the entire State, and there seems to be no question about his successor, as shown by the following quotation from the *California Fruit Grower*: "Commissioner Cook has appointed, to succeed Mr. Brenner, the latter's deputy, Frederick Maskew." Also from the same column I read further on, "The criticism in this matter does not reflect in any way upon Mr. Maskew, however." From the above it seems that, while no one questions the ability of Mr. Brenner's successor, all are flaying Dr. Cook for Mr. Brenner's removal. Owing to the long service of Prof. Cook, and our knowledge of his ability as well as integrity, beekeepers will be slow to condemn until he has had time to get his forces in working order and prove his actions. Surely we are not ready to admit that Mr. Brenner is the only capable man California has for this position. Dr. Cook was not appointed for political reasons, but for his unquestionable ability, and he was appointed by Gov. Johnson, in whom the great majority of California people have unbounded confidence. It is true that some of his appointees have not been satisfactory to all, yet they seem to "make good" in the end; so let us reserve our judgment until Dr. Cook has had sufficient time to "make good."

* * *

CARLOAD SHIPMENTS OF BEES FROM UTAH TO THE ORANGE GROVES OF CALIFORNIA.

Serious objection to the shipment of bees from Utah and Nevada to our orange groves, for early spring breeding, has developed. A part of this is based on the fear that disease may be brought in, and the rest because of the danger of overstocking our ranges. The former is an objection worthy of serious consideration; but this could be easily overcome with prompt inspection by a competent inspec-

tor who could destroy all diseased bees and honey. Now note, I said, "*bees and honey*," not hives and wax. A short time ago I read of an injunction that had been served on an inspector at Lindsay, Cal., to prevent the burning of 300 colonies of bees. It makes my blood boil when I hear of an inspector burning up bees, hives, and all. The hives are worth at least \$1.50 each, or a total of \$450. Eighteen combs per extracting colony will produce 5 lbs. of wax worth 25 cts. per lb., or \$1.25 per colony, \$375, or a total loss to owner \$825. This is not only an economic waste, but useless destruction—absolutely useless—and practiced simply to get rid of the disease the quickest and easiest way possible, regardless of the loss to the owner. Why can not common horse sense be used in these matters? People do not burn a house because it has been infected with disease. Why not? Because it can be disinfected and made habitable again. So can a hive.

As to overstocking, it might be well for some of our local men to observe what used to be considered a beekeeper's moral right to a territory within reasonable range of his location, but which at this time is totally disregarded, there being at this time hundreds of colonies moved into the orange from the sage-fields that will probably be left on my range the entire season, owing to the failure of the sage. The Redlands orange district will support 40,000 colonies, if properly distributed, during the orange flow. But the range I am on is only sufficient for my bees to get a good living after the orange is over, and I must suffer more from this overstocking of my range this summer than thousands of colonies from Utah and Nevada would cause during the orange flow.

No man should expect his rights to be considered who does not consider the rights of others. But when tons of orange honey is going to waste daily we can supply many thousands of colonies better than we can a few hundred extra on our ranges during the summer months. Mr. M. A. Gill, of comb-honey fame, said at the banquet-table during the California State convention, "Boys, come on to Utah if you wish; we can take care of part of you but not all." Let us be as liberal, and say, in return, "Boys of Utah and Nevada, come over to the orange groves if you like, and build up your bees; we can take care of most of you, and we may want to take our bees and go home with you to share your benefits."

Conversations with Doolittle

At Borodino, New York.

WHAT ARE SUPERS AND UPPER STORIES?

"What is meant by supers?"

"In the Standard Dictionary I find that a super is, 1, Above in position; 2, Above in degree or amount."

"Then when the term as applied to bees it would mean the putting of an extra hive of combs above the hive the bees were already at work in, would it not?"

"Yes, if no specifications were made. But that would generally be called 'putting on an extra story;' or making a single hive into a two-story one. If another hive were put on, it would be called a three-story hive.

"Some beekeepers call what you term a two-story hive a hive with a super on; others talk about supers for extracted honey, and still others about supers of sections, either empty or with baits. Will you please explain this matter so we beginners can understand what you veterans are talking about?"

"A two-story hive could very properly be called a hive having a super on it for extracted honey. But a super for extracted honey is not always the same depth as the hive proper, for very many of our best apiarists use a much shallower box, although of the same dimensions otherwise, than the hive below. Hence the term 'extracting super' generally means any receptacle holding combs, and it may be from one-half to two-thirds of the depth of the hive below. If this 'super' is not filled with combs already drawn out it would probably be called an empty super, from which the veterans would expect that the frames used in it would either have starters in them or else be filled with comb foundation. However, in this case it would be better to say that a super with frames having starters in them, or a super with frames of foundation, was put on top of the brood-chamber.

"A super of sections is a box, generally of the same dimensions as the hive, except as to depth, filled with sections to hold the comb honey. This super is made a *beeway* deeper than the sections are tall, and in this way one, two, three, or more supers of sections can be piled up above the hive or brood-chamber. A super of empty sections would be understood to mean that the sections had only starters in them. The veteran might also understand that each section was filled with very thin comb foundation; but where this is the case, the expression 'filled with foundation' is generally used. 'Bait sections' are sections in which the bees

have worked the season previous, drawing out the foundation or building comb therein, yet not finishing their work to an extent sufficient to make the honey in the section marketable. The honey is removed from these unfinished sections generally, by having them cleaned out by the bees in the fall. Then one section, filled with this now empty comb, is put in the center of each section super put on at the beginning of the season. This empty comb has a drawing tendency, and the bees begin work in the sections much sooner than if only starters or full sheets of foundation were used.

"When I began keeping bees, forty-three years ago, comb foundation was unknown. Then comb of the worker size of cells was cut into strips about one inch thick, and by means of melted wax was attached to the under side of the top-bars of the frames. These were frames having starters in. For starters for comb honey, only *white* comb was used, no matter as to the size of the cells; and this was, with melted wax, attached to the under side of the tops of the sections. These white combs were cut into triangular pieces, the size of each being in proportion to the amount of white comb on hand. With the advent of comb foundation this was used instead of these starters, a strip of about an inch in width being considered the best for frames, and a triangle of about $1\frac{1}{2}$ inches on each side as being right for the sections. However, of late years there are few beekeepers who do not fill the sections nearly full of foundation."

"You said one section should be used as a bait. What about the expression 'supers with baits,' as it is often used?"

"It may mean forty supers of sections, each super having one section of drawn comb in it. But it would be more apt to mean that each super had more than one bait section in it. If one bait section has a drawing tendency for the bees, more of them will draw harder. The tendency is to draw the bees from the brood-chamber at the beginning of the honey-flow, so that work will not only be begun in the sections sooner, but that the swarming fever need not be contracted, as it almost always is by the massing of the bees in the brood-chamber at this time in the season. For this purpose four baits are much better than one, and four times four very much better yet. If the entire super can have all the sections full of clean, nicely built combs from the year before, the swarming tendency would be very largely overcome."

General Correspondence

THE ADVANTAGE OF TRIANGULAR TUBES IN A CAPPING-MELTER

BY F. A. POWERS

Mr. F. J. Severin's capping-melter, described Dec. 1, p. 722, is in the main modeled after one that I made. He has made an improvement in placing the gasoline-tank off the stove outside the building; also in using a wooden block in the top of the hole where the knives are heated. But in some important points the Severin machine is faulty. The space between the tubes should be $\frac{1}{8}$ inch instead of $\frac{1}{4}$. If the spaces are larger than $\frac{1}{8}$ inch, bits of cappings will pass through and slide out at the spout without being melted. Then the spout should be the full width of the machine, just a continuation of the bottom that the honey and wax fall on after passing through between the pipes. This makes it easy to clean out the space under the pipes. The triangular shape for the pipes is better

than the square, for the reason that the cappings that pass between the pipes are melted by the heat from the flat under surface of the pipes as the cappings slide along under them.

The place where the knives are heated should be larger, or extend clear across the machine, so that the evaporation will not lower the water so fast. The picture on page 724, Dec. 1, is a pretty fair representation of my own machine except for the changes I have mentioned. It is rather larger than is necessary, as eight pipes 18 $\frac{1}{4}$ inches long are all that two gasoline-burners will heat, and it will take two good uncappers to keep the water from boiling,

even with the burner going full blast. The water should never boil.

AN UNCAPPING KNIFE THAT HOLDS THE HEAT

To make an uncapping knife to use with this machine I solder a good thick sheet of copper to the flat side of a Bingham knife, letting it extend to within 1-16 inch of the edge, and bevel it off. The knife will then hold heat long enough to uncap both sides of a comb, and the copper will convey it to the edge, where it is wanted.

AN INSULATED SEPARATOR.

The lower drawing represents a wax-separator to use in connection with this melter. It is a 10-lb. lard-can with a piece of tin soldered on the inside to divide it in two parts, the tin extending to within $\frac{3}{4}$ inch of the bottom. The can is inclosed in a box with insulating between the box and the can. This arrangement does not injure the honey if kept going pretty lively; but otherwise the honey and wax remain in the separator so long that the honey is slightly injured.

Parma, Idaho.

A CAPPING-MELTER DESIGNED TO AFFORD A QUICK EXIT FOR THE HONEY AND WAX

Description of Comb and Capping-melter

BY H. BARTLETT-MILLER.

Having been blessed one season with a large harvest from about a hundred colonies, only to discover that the honey was non-extractable, and having had to leave during last year all my clover honey on the hives till winter, when it became as solid as a board, I determined to invent an improvement upon all the comb or capping melters of which I had read.

I had seen home-made melters—big, ponderous, and awkward. Truly they were "fearfully and wonderfully made," and worked—*sometimes*. Heat, radiated from a melter, I considered intolerable to the operator, besides being a source of waste. Therefore as a water-jacketed wall was meant to radiate heat inward in order to melt honey, it must also radiate exactly as much outward, resulting in unbearably stuffy honey-houses. So I eliminated the water-jacketed wall. There remained only the bottom, which, perforce, must be made larger to offset the lost heating surface of the walls. But a bottom too large meant hot honey blocked from the exit till it be-

came more or less deteriorated. Then, too, a large exit had to be provided for the pollen and slumgum. My final plan was to increase the bottom surface by ridging it and putting a piece of angle iron loose in each gutter made by the ridges to carry away all melted honey as soon as it could run.

Previous experience had taught me that the outside, or what I term the "receiving gutter," must be water-jacketed. The experience was not my own, however, but that of a friend whom I found down on the floor of his honey-room muttering language "not loud but deep" while he shoveled up about 50 lbs. of cold wax and honey which had overrun through the wax, chilling and stopping the gutter.

This melter of mine radiates no noticeable heat, as the sides containing water are nowhere higher than about three inches; and the necessity for inclosing it in any

and down the ridges and gutters being thus rounded, as it is not important to hammer each bend to an acute angle. I thus obtained considerably more heating surface than the bare length of the bottom. As soon as the honey and wax melt they run down the slope of the gutter, and are received beneath the angle iron or bridge piece, made by bending at right angles pieces of iron about $1\frac{1}{2}$ or 2 inches wide, and as long as each gutter, and notching the edges deep enough to allow a full cell of pollen to get through. The flow of the honey carries along all the slumgum to the exit into the receiving trough through the holes in the side of the melter at the end of each gutter. After the bottom is soldered in, cut or drill for each channel iron a $\frac{3}{4}$ -inch hole in the wall of the melter on the receiving-trough side, and file the bottom of this hole to the shape of the bottom of each gutter so that

no projection may prevent any solid matter floating into the receiving trough.

I made my melter wide enough from front to back (the receiving-trough side being front), so that an L. frame would rest inside the melter, and deep enough to clear the bottom by three inches, so as to hold frames while a good layer of honey was melting. My melter has nine gutters; but it could be made any length if not too cumbersome.

Besides the holes for exit from the channel iron to the receiving trough, one should be punched at one end into the water compartment and a small funnel piece soldered on for a filler.

The bottoms of the gutters need not be more than one inch above the true bottom. This will bring the ridges about three inches above the bottom; and with the large heating surface the thin layer of water heats quickly, so that, when in full swing, the ridges are nearly always full of live steam beneath, and all pollen and solid matter run outside without that damming back of melted honey, which is the one great drawback with many melters I have seen planned, unless they are too slow for practical purposes.

sort of box is entirely obviated. Any handy man can make his own. I made mine in a few hours. All the soldering to be done is around the inside, on the ridged bottom, the ends of the gutter, of which one, of course, and the corners of the container itself, is blocked up.

To bend the bottom I nailed a piece of stout timber on a bench so that a sheet of galvanized iron would go under; and, having marked crosslines the full width of the bottom, three inches apart and exactly parallel, I just bent the iron to the marks up

When old brood-combs are melted, the cocoons, after some four hours' work, stick to the bottoms of the notches on the sides of the channel irons, and it is wise at each midday stop to clean this out. It does not take more than five minutes. I use for this purpose a piece of wood cut to fit the gutters. I had, perhaps, an extra lot of this to contend with, because I always lift up the brood-chamber except one frame, to prevent swarming; and, of course, the pollen was simply filled over with honey. Yet I melted over 700 lbs. of honey from such combs in four hours, cutting the combs from wired frames, and leaving the wires in the frames. The melter often got ahead of me, running empty except for a little rubbish. If I ever make another it will have twelve gutters so I can fill it up and leave it for half an hour. This one of nine gutters is such a glutton that it needs constant feeding.

It is well, when the soldering is finished, to make a frame of $2 \times \frac{7}{8}$ stuff, and run a sawkerf all around the middle of one edge to fit the top edge of the melter. Then drive a few fine nails through both wood and iron. The top is thus nicely stiffened, and a handle made for carrying.

I have not mentioned the honey and wax separating vessel, as all practical men know how to manage that part of the business. For a shelf or support to work on I cut a piece of $\frac{7}{8}$ stuff to fit over the top frame with a notch at each end, so I can slide it from end to end. I bore a hole about six inches from one end to push the end of the frame in, and cut out the combs. I have not tried cappings, but I know the melter would simply romp away with them. For heating I use a blow-torch. It is noisy, but it makes the honey run, and there is no discoloration. The honey really does not have time to get discolored. I have yet to find any bad effect from the zinc in the galvanized iron. As a student of chemistry I know zinc is harmless in this case.

The angle irons must be soldered in pairs or more at one end by a narrow strip extending over a ridge or ridges, and attached to the top of the angle iron; otherwise, instead of straddling the gutters they would fall over, so that both notched edges would be lying on one slope. It is advisable to remove all slumgum at any long stoppage, because while it does not interfere with the flow of the melted honey, any great amount of it would stain any white honey going through it. All my clover honey was in comb built from starters in wired frames intended to be kept for extracting only, as mostly drone was built. It was produced above excluders; had a small amount of

pollen, and was absolutely as white when put up after the melting as if I had extracted it in the usual way. The non-extractable lot of last year's crop was slightly darkened after about six hours' run without cleaning; but it was dark before melting any way, as it was in old brood combs.

Kihikihi, N. Z.

[This melter is somewhat similar to the one described by J. W. George, p. 667, Nov. 1, 1909, except that the "gutters" are deeper and there is an exit at the end of each one. The plan described by Mr. Powers in the preceding article would probably be more efficient still.—Ed.]

HOW TO GET RID OF CAPPINGS

Some Experience with Draining-cans Made of Galvanized Wash-tubs; a Capping-press

BY MAJOR SHALLARD

The ordinary uncapping-box, like the McIntyre, with wire screen to drain out the honey, has never appeared to me to be a good utensil. It is too bulky; it is hard to get the cappings out of it; and when they are out, and it is not in use, it takes up a lot of room. If it is lined with tin, care must be taken that it does not rust. If one takes the cappings out with his hands it is a messy job; and if a spade is used, there is danger of injuring the fixings.

My first uncapping-can (in 1884) was like Dadant's. I did not like it. Any cappings that were left in it over night had to be taken out, because it would not do to put fresh cappings on top. It was hard to empty by hand; and, on account of its depth, a spade could not be used. Then when not in use it had to be kept inside, taking up valuable room. I discarded it and got ordinary galvanized wash-tubs. When these tubs are not in use they can be packed one in another, and left outside in all kinds of weather. They make a compact parcel to take to outyards, and afford an easy way to carry cappings home. I got the largest tub on the market and one of the second size, and punched the bottom of the larger one as full of holes as possible, with the tang of a file. I shall never forget the look of astonishment on the salesman's face when, after buying the tubs (I bought 18, as I was running 800 hives at the time), I punched several holes in the bottom of a large one. I put this large one into the smaller one, and it fit tight. The large tub is 28 inches across the top by 12 deep; the small one is 26 inches by the same depth. The large tub will hold all the cappings from 500 combs. I got two pieces of wood 32 inches long, $1\frac{1}{2}$ wide, and one inch

thick. I nailed these together 9 inches apart, and slipped the ends of one piece through the handles of the tub, thus holding it in position for uncapping. After the day's work is done this is taken off the top. The top tub is lifted, and the wood put between. In the morning the bottom tub is nearly full of honey. The top tub is lifted off and put into another small tub and left to drain. The tub with the honey in is lifted up to the extractor and poured through it into the tank. When another tub of cappings is ready it is placed on top of the first lot, and so on.

I used this method for some time, and then I got tired of having cappings around. The rats got at them; also the moths, and they were always an incentive to the bees to rob, and so I made a press. The box is of 1¼-inch stuff, halved at the corners, and nailed both ways. It is 17x12x17 inches each way. The sides are lined with slats running from top to bottom. Across the bottom three pieces of 3x1 hard wood are nailed, and across these more slats. This box stands on a 4x4 hard-wood frame. The two uprights that carry the crossarm at the top are mortised through this frame and fastened with wooden pins so that, when the pressure is applied (with a carpenter's iron bench-screw), it pulls this frame and the crossarm toward each other, and does not shove the slatted bottom off the box. The follower is a square box made of inch wood to fit the press, and is 11 inches deep. It has a piece of 3x2 hard wood let in under the lid, and another piece on the same side, inside the bottom, to take the strain. The 4x4 frame stands on legs, and there is a galvanized-iron tray (to catch the honey) which holds 60 lbs. After I got this press at work, instead of standing the tub or tubs of cappings away in the corner they were lifted over to the press and the cappings shoveled into half a chaff bag, and the honey pressed out. The shovel may be allowed to slide right along the bottom of these tubs, and it will not hurt them a bit.

The cakes of cappings come out as hard as a stone, 17x17x3 inches, as the press is strong enough to allow the most powerful man to screw it down as hard as he is able.

To give some idea of the strain, I might mention that we broke several crossbars, made of ironbark, 6x2½ inches. Since then I have made one 6x4 of the same wood, and no one is strong enough yet to break that. I got some boxes with lids to store the cakes in; but they were not satisfactory. The rats gnawed holes through them, and some hives were filled too full, and the lid would not shut, so I got a square iron tank. These are procurable all over Aus-

tralia. They are made of one-sixteenth black iron riveted together, and are 4x4x4 feet, and 3x3x3 feet, with a manhole in the top, and a close-fitting lid. The one I got had a crack in the corner where the iron had split when being folded; and when it got hot from the sun (it is kept in the open) more honey ran out of the cakes and out of this crack. When I found this I tipped the tank toward that corner, and now the bees do a regular business when there is no flow on. I know of no practical way of getting *all* the honey from the cappings. I have carried the tubs out, and have let the bees get at the bottoms after we had finished extracting, and they got the most of it; but I doubt if the game is worth the candle.

For many years I used solar extractors to get the wax from the cappings, until I found that a friend was getting more wax from much fewer bees by boiling the cappings in a bag, the same as depicted in the A B C and X Y Z of Bee Culture. I then tried treating the slumgum; but the result was not satisfactory. I got a block of dark-gray wax; and after treating this with acid I got three-fifths light and the rest rubbish. Then I tried treating the whole lot in the bags the same as my friend did; but I did not like that either. Then I tried tipping the whole lot into a copper and treating it with acid the same as mentioned in the A B C book; but in that description cakes were put in without refuse. I dipped off all I could, but found too much left behind to cool, mixed with refuse. I thought the honey had something to do with this result, so I soaked my cappings in bags in the creek for 48 hours, and the result was much better. Still, it was not satisfactory. Then I altered it. I dipped off what I could, and put the rest through the press; and, judging from appearance, there is but very little wax in the refuse. This is much the best method so far, but it is not satisfactory. It is too slow, and there is too much labor, so I have purchased a German wax-press, and I mean to see if that will help to expedite matters.

South Woodburn, N. S. W., April 16.

[From experiments that we made, it seemed to us that it is a pretty slow process to press the honey from the cappings. On this account we prefer the capping-melter; for, although certain kinds of honey are injured slightly, one can hardly tell the difference unless the honey has been allowed to stand a long time in the melter or in contact with the hot wax, and the results every other way are certainly much more satisfactory.—Ed.]

Fig. 1.—Portable extracting outfit of Geo. H. Kirkpatrick, Rapid City, Mich.

AN EXTRACTING-OUTFIT ON A LIGHT SPRING WAGON

BY GEO. H. KIRKPATRICK

When I first established a system of out-yards it was my practice to build honey-houses at each yard; but I have discontinued their use for various reasons. The lumbermen cut away the timber, then the raspberries follow; but these fail when the farmer clears the land and fits it for the plow, so that the beekeeper must move on to a new location. For three years, therefore, I have used the extracting-wagon as shown in Fig. 1. The framework for the top is the same length and breadth as the platform, and 6 feet 4 inches thick. The top is covered with canvas, and the sides and ends with wire screen, the door being in the back end.

Toward the front of the wagon is a tank which has a capacity of 700 lbs., on the top of which is an uncapping-can. The tank is fitted with a gravity strainer, and the honey is drawn from a gate under the wagon. With my two-frame automatic extractor I can, with the help of two boys, remove from the hives, extract, and put in cans, 2000 lbs. of honey per day.

When the honey in the upper super is nearly all capped we begin extracting. Thirty-four 60-lb. cans in the wheelbarrow

are placed in the wagon, the team hitched on, and the boys and I are off to an out-yard. When we arrive, a convenient place is chosen for the wagon. We find it is always best to locate it where the ground has a little slope, as it is easier for the team to move it when it is loaded. When the whole outfit is located, an adjustable post is placed under each of the four corners of the wagon to hold it steady. As the supers are carried in, they are placed on the right side of the wagon and transferred to the left side when emptied.

Fig. 2 shows eleven colonies at the close of an eleven-day flow from milkweed in July, 1911. These eleven colonies produced 1320 lbs. in this time.

MOVING TO FALL PASTURE

The harvest of raspberry and milkweed closes about the middle of July. We extract the honey and get it into the cans as quickly as possible, then prepare about half of the colonies at each apiary and move them to buckwheat or the willow-herb. A queen-excluder is placed over the brood-chamber, a super containing a full set of combs is put on, and a wire screen set on top. A wire screen for the entrance is also dropped before each colony. When the bees have stopped flying late in the evening, I take a hammer and smoker and a few crate staples, and soon have thirty colonies

Fig. 2.—Eleven colonies that produced 1320 pounds of milkweed honey in eleven days.

ready to load. I first close the entrance, then fasten the bottom of the super, and finally the screen, using the crate staples to do this. I load the bees in the evening and move them the following day.

Fig. 3 shows my wagon built especially for hauling bees. Not many beekeepers use spring wagons, but I use no other. The load shown in this illustration was drawn seven miles; and when I was within a few miles of my destination I was so unfortunate as to throw from the wagon eleven colonies. I am a lover of the camera, and carry one with me nearly every time, and I brought it into play at once, as shown in Fig. 4. This was in hard-timber stubble land where the red raspberry flourishes.

Fig. 5 shows a load of supers. A $\frac{3}{8}$ -inch rope is passed around the load a few times and made fast by tying the two ends together. The slack is then taken up by drawing the rope down at one point and upward at another, forming a zig-zag line which is held in place by nails driven above and below.

RADISH HONEY

Early in the season of 1911 I learned that an agent, sent out by a seed company, had contracted with the farmers in an adjoining township to grow radishes for seed, 300 acres being grown within an area of

nine square miles. Wishing to know whether the radish is a honey-plant I moved 32 colonies to this location. Owing to the early and late planting, the blossoming began in July and continued until frost. I made three visits to this apiary during the season, and each time found many bees working on the radish bloom. It is a good pollen-producer, but I fear it does not amount to much for honey. I extracted some honey and found it of good body and fair flavor, though a bit spicy, and the color was light cherry red.

Rapid City, Mich.

DRAINING OUT MOST OF THE HONEY BEFORE MELTING THE CAPPINGS

A Combined Uncapping-box and Capping-Melter

BY E. L. SECHRIST

Honey, in this locality, granulates so quickly that cappings become one solid mass in a very few days if allowed to stand and drain, so some kind of capping-melter seems necessary.

The two I have used this season were very satisfactory, both being of the same design, one 5 feet, the other 6 feet long. Seven or eight feet might be even better if there were space in the extracting-room for

it. They are easily made, and not expensive.

It is, in principle, a McIntyre uncapping box combined with a melter, the melter being confined to a space of two feet at one end of the box, under which is a water-tank to be heated by a one-burner oil-stove.

The box is 6 ft. long by 2 ft. wide, of $\frac{7}{8}$ inch boards, 12 inches wide, nailed to 2x4 legs 32 inches long. The bottom is a sheet of galvanized iron with edges turned up from 1 inch at the rear to 3 inches at the front, then turned outward 1 inch for railing to the bottom edge of the box. This gives a drop of 2 inches from the rear to the wax outlet. This pan is nailed to the bottom edge of the box, and another board is nailed to the legs below the iron, as shown, supporting the iron bottom. At the heater end there is a box enclosing the stove to prevent drafts and to confine the heat. A door admits of lighting the stove and of removing the oil-tank for filling.

One side of the water-tank projects beyond the box, forming a place for filling the tank in which knives may be heated.

A two-inch-high partition or honey-stop is soldered in V shape to the top of the galvanized iron pan, separating the draining space from the melter proper. At the inner point of the honey-stop is a hole

where the honey draining from the cappings runs down into a little half-round trough under the iron bottom, and thence into a bucket at the side of the box.

I use a $\frac{1}{4}$ -inch-mesh wire screen over the 4x2-foot draining surface; but a slatted train board may be used if desired.

When working, the cappings fall on any part of the draining surface; and as they drain they are shoved along toward the melter, finally being shoved off the draining-screen, which rests on the honey-stop, separating the draining surface from the melter, and dropping on the heated melter, where they gradually melt, and wax and honey run down the inclined surface into the wax-separator.

About three-fourths of the honey will drain from the cappings and run out of the side spout, never being heated at all. The remainder of the honey runs out with the melted wax, and is a shade darker and a bit off in flavor from being heated with the dark cappings. We kept this heated honey separate in extracting the lighter grades of honey; but with the darker grades we put it with that which came from the extractor and draining surface.

In uncapping 1500 lbs., about 10 to 15 gallons of honey will drain from the cappings before they reach the melter. If not

Fig. 3.—Kirkpatrick's wagon, built especially for moving bees.

Fig. 4.—Eleven colonies tipped off by accident.

more than 1800 or 2000 lbs. is extracted in one day, the cappings may drain over night and melting begin the next morning.

I like this melter, because while it serves, primarily, as an uncapping-box and drainer, getting out as much of the honey unheated as can drain out in the time allowed for draining, which depends on the length of the box and the rapidity of extracting, there is no extra apparatus required for

melting, and no handling of sticky, messy cappings from one box to another.

The cappings are entirely cleaned up in the one machine, and with proper wax-separators the cakes of wax may be removed as they cool. The warm honey goes into the strainer.

In this locality the nights are often so cool that extracting early in the morning is not practicable, as the honey will not go through the strainer. There are many days, also, that are so cool that honey can not be thrown out

clean from the combs with the hand extractor. The power extractor will throw out the thick honey, and I am planning to heat all my honey, next season, before it goes into the strainer. Our thick alfalfa honey, when cold, goes through the strainer slowly and clogs up the cloths very quickly, and the gravity strainer is not practical for our use. Has anybody used such a heater?

Locality is such a varying factor that

Fig. 5.—Load of supers secured with a rope.

One of E. L. Sechrist's apiaries, Clarksburg, Cal.

what is entirely practical in one place is useless in another. For instance, we could never think of producing bulk comb honey, as much of our honey granulates from two days to a week after being taken from the combs, and granulates in the combs in a month; so with bulk comb honey we should have a solid, unsalable mass.

Clarksburg, Yolo Co., Cal.

IS A HIGH PRICE FOR HONEY ALTOGETHER DESIRABLE?

BY E. W. PEIRCE

'Tis said, "When young folks talk to old folks they should know what they're about." If, therefore, in the course of this article I shall go counter to the tenets of my elders in the profession I beg that those seeming fallacies be charged to "youth" rather than to any desire to occupy an arbitrary position. A baker's dozen years of experience as a keeper of bees and producer of honey on a small scale, together with a number of years devoted to the buying and selling of honey may possibly entitle me to a corner in the councils of the wise.

In reading the compositions on the subject of selling honey appearing in the vari-

ous bee journals during the last few months I have been impressed with the dominance of one specific note—"How get higher prices?" So persistent has been the harping on this one string that I am venturing to voice my sentiments here, even at the risk of striking an unpopular chord.

Let me say at the outset that I have no desire to quarrel with any of my good friends the beekeepers (and thus jeopardize my daily bread). Our interests are mutual; and if anybody is in a position to rejoice with them in prosperity and mourn with them in adversity, surely it is I. Moreover, the threefold nature of my relation to the trade should enable me to view the subject from different angles and discuss it in an unbiased way.

Any legitimate effort, either of producer or dealer, to secure good prices is commendable. But is it not true that the advocates of higher prices too often in their pleadings totally ignore certain factors that must enter into the problem?

There is one law that never has been and never can be repealed—the law of supply and demand. Combination and manipulation may for a time suspend its operation, but there is a perpetual equilibrium in the sphere of economics that necessitates its reinforcement. Why are eggs quoted at twelve

Sechrist's combined uncapping-box and melter. Three-fourths of the honey drains off before the cappings reach the hot surface, so that only about one-fourth is heated.

cents a dozen in June and forty cents in January? Simply because in June the supply balances demand; whereas in January demand outweighs supply. "Cornering the market" may modify the price to a considerable extent, but there is a limit that can not be exceeded without curtailing the demand. Were the cold-storage men to advance eggs to two dollars a dozen, even assuming that they could control the entire supply, how many of us would eat custard pies?

Let us now apply the same reasoning to the honey situation, not losing sight of the fact, however, that eggs are a staple—a *quasi* necessity—whereas honey is admittedly a luxury. Even at the exorbitant price suggested, there would be an appreciable though almost infinitely diminished demand for eggs. In the case of honey, even a small fraction of this coefficient of expansion would be in effect prohibitive.

It is true that, in many cases, the individual beekeeper can develop in his immediate neighborhood a demand for his honey at any price within reason, and he is entitled to the highest figure he can command. But we are considering the market in its wider scope. I concede that, in the larger cities, there is quite a large fancy trade that will buy luxuries almost regardless of price. Yet this is a small proportion of the purchasing population of these centers, much less of the country at large.

The amount expended by any community for various commodities is determined chiefly by the wage-scale and the price-current, other conditions being normal. Obviously, necessities must come first; and the amount, if any, in excess of what is required for these must suffice for luxuries. At best the margin is small. Our city of thirty thousand is perhaps a typical one, most of the citizens being of the wage-earn-

ing class, and the consumption of honey here is probably about the average. My observation, covering a period of years, has been that, when comb honey retails at 20 cents or less per average section, there is a staple demand; but if the price be increased to 22 cents, there follows a shrinkage altogether out of proportion to the advance. In other words, 20 cents is the "dead line"—the limit that can not be exceeded if a healthy demand is to continue. I could wish that the standard price might be higher here and everywhere. Gladly would I see both producer and dealer secure the larger profit. But, to quote one of our former presidents, "It is a condition and not a theory that confronts us;" and any attempt on the part of either the National Association or any other organization or individual to "bull" the market, to the utter disregard of these considerations, must necessarily react by cutting down the demand for honey,

and thus frustrating at once its very purpose.

To make my position clear, allow me here to introduce the much "cussed" and discussed "Karo corn syrup." Why are such immense quantities of this syrup consumed? First, because of the able and persistent advertising of its merits; second, because, to the average taste, it is palatable; third, and chiefly, because it is cheap. It is not my purpose to advertise Karo, albeit we may as well admit that it is here to stay. Nothing is gained by shutting our eyes to the truth, nor will misrepresentation or detraction alter the facts. What is "corn syrup"? A variable mixture of glucose, or grape sugar, and other invert sugars, etc., manufactured from corn starch by the action of dilute acids. Karo and other cheap syrups consist essentially of corn syrup with a small percentage of cane-sugar syrup added to intensify the sweet. The only valid objection to pure glucose or any sugar of its class is its inferior sweetening power, it being only about half as sweet as sucrose or ordinary cane sugar. According to the best authorities it is not injurious to health; on the contrary, being (like honey) "inverted" — predigested, as it were — it is more readily assimilated than cane or beet sugar. It is the form in which sugar generally exists in fruits, etc., and the substance into which the starch of our food is converted by the digestive ferments before it can be utilized in the vital economy.

As to palatability, that is another question; and, as a Latin professor used to remark, "De gustibus non est disputandum," there is no disputing about tastes. I must confess that personally I am not averse to the use of the lighter-colored of these syrups as an occasional change from more pronounced sweets, though I freely grant that the best of them is a far call from

white-clover honey. But mix them—take half honey and half *white* Karo—and see what you get. "Lickin' good!" Try it for yourself.

Now, instead of running down these syrups and attempting to bull the honey market without regard to the ratio of demand to supply, would it not be wiser to publish broadcast such a recipe as the foregoing, if by so doing the demand for honey could be, as it undoubtedly would be, materially increased? If honey is ever to have its rightful place as a staple along with bread and butter and sugar and meat, it must be popularized. This can be accomplished only by systematic advertising of its virtues, and by its production on a scale that will allow delivery to the consumer at a reasonable price.

What is needed is not higher prices regardless of any and all other considerations. The situation demands, instead, *more*

B. B. Hogaboom's combined gravity strainer and automatic device for closing the gate when the can is full.

A large lot of bulk comb honey in Mason jars being heated by the sun to retard granulation.

beekeepers, better beekeepers; more bees, better bees; and, as a natural result of improved methods and intelligent management, *more honey and better honey,* so cheaply produced and so widely distributed

that not only will it be profitable alike to producer and dealer, but even the humble toiler can well afford to use it with his daily bread.

Zanesville, Ohio, April 11.

The New 60-speed engine made by the Gilson Manufacturing Co., Port Washington, Wisconsin. The particular feature of this engine is the jack-shaft and series of interchangeable pulleys by means of which 60 different driving speeds may be secured, so that the engine may be used to run any thing from a grindstone to an emery wheel without expensive pulleys, shafting, and belts. This should appeal to the beekeeper.

[We have no doubt that some of our subscribers will take issue with Mr. Peirce, especially as to his proposition relating to glucose or Karo. While we do not know the exact character of Karo, we do know that some authorities claim that glucose, because of the difficulty of eliminating all the acids used in its manufacture, is not altogether a wholesome food. We admit that some chemists claim that glucose, while having a very low sweetening power, is not unwholesome; but they evidently refer to an article that contains no residue of acid or neutralizing salt. A few years ago it was reported that John D. Rockefeller, reputed to be interested in the manufacture of glucose, would give one hundred thousand dollars to any one who would discover some process for eliminating absolutely the acid used in the making of it. We have never heard that the hundred thousand was taken. At all events, commercial glucose at least contains something that the makers would like to get rid of.]

We have never tasted glucose or glucose preparations without having a very unpleasant after-taste, best described by the term "brassy." Some years we partook of common commercial glucose quite freely—ate it three times a day, to see if we could acquire a taste for it. Our digestion was upset for two weeks; and to this day glucose, even a slight taste of it, brings back the feeling of nausea which we shall never forget.—ED.]

A COMBINED STRAINER AND AUTOMATIC CAN-FILLER

BY B. B. HOGABOOM

For two seasons I have used my patent strainer and automatic can-filler, as shown in the photograph, and I find that the outfit is perfection itself. The strainer can is 40 inches in diameter and 16 inches deep. The circular screen for straining is supported $1\frac{1}{4}$ inches from the outside and from the bottom of the can, while the honey remains within $3\frac{1}{2}$ inches from the top all the time as it runs from the bottom of the strainer through a tube up to the gate. A small pan (not shown in the photo) 12 inches in diameter, $\frac{1}{2}$ inch deep, is $\frac{1}{2}$ inch below the surface of the honey in the strainer can; and it stops all cappings of wax particles $\frac{1}{2}$ inch below the surface of the honey, and they at once start to rise from this level instead of going down and coming in contact with the screen, as they would do if no pan were used.

This strainer may be used day after day without becoming clogged unless the honey

is partly granulated. If it is granulated I have a sectional screen by the use of which the solid portions settle on the lower part, while the honey strains through the upper part of each section. The parts of this sectional screen are detachable, and may be cleaned very quickly. This is not necessary except in case of large quantities of granulation, which very seldom occurs.

The automatic filler is shown very plainly. The valve closes instantly when the desired weight is reached. This is automatic, and can not miss, as the valve is perfectly loose, with not one particle of friction until it reaches its seat, where it is firmly clasped with a spring. The rod reaching from the filler to the balance is in two sections, one going inside of the other, secured by set-screw so it can be hung at any height—preferably from $6\frac{1}{2}$ to 8 ft. from the floor, which is out of the way. This device is also detachable from the strainer, fitting any size of strainer can. I usually arrange this automatic filler with an electric bell which always announces to the operator that the can is filled. There is about $3\frac{1}{2}$ inches of space from the level of the honey in this can to the top while running. This extra space would hold about 10 gallons, which avoids all danger of overflowing while changing cans. By the use of this complete device there is not one moment lost during a day or week in extracting, except to remove the full can and replace the empty—no cleaning of strainer, and no overflowing of honey. The small gate at the bottom of the strainer-can is used only to draw the remaining honey after the yard has been extracted.

Elk Grove, California.

[As can be seen, this is really a gravity strainer, with a screen to strain out the larger bits of comb, etc. It would seem as though the can should be deeper, but if our correspondent finds that this depth renders the honey sufficiently clear, then a deeper can would be of no particular advantage.—ED.]

PACKING BULK COMB HONEY IN GLASS

Liquefying Candied Honey by the Sun's Rays
without Melting the Comb

BY J. J. WILDER

When I began the production of bulk comb honey in a wholesale way I used large-mouth cans and pails to pack it in; but I soon found that it was not best to pack it thus, especially for the local market. On account of the low freight rate, tin is all right for shipments over three or

four hundred miles; but for shorter distances the trade prefers it packed in glass, because it thus sells far better and for a better price, so long as the article is fancy. The local trade takes to this new way of packing the honey very well where the people are familiar with honey; but when it comes to building up a trade or demand, it is slow work. So, taking all things into consideration, we have found it better to pack all the light honey in glass and the off or dark grades in cans and pails.

After trying nearly every kind of glass packages that could be used for this purpose we have adopted the regular Mason fruit-jars—quart and pint size—and we have found more demand for the latter size. Of course the honey thus packed is neatly labeled with our name, address, and guarantee.

ADVANTAGE OF MASON JARS.

Aside from the demand, there are many other advantages in this package to the honey-producers. They can buy the jars at almost any grocery, and get them at a greatly reduced price at any wholesale grocery by taking a considerable quantity of them.

Then the jars come well packed in good corrugated paper cases—12 jars to the case. The covers of the cases are only slightly pasted down, and can be easily and quickly removed. The jars are usually clean, and all that is necessary is to rinse them in clean water. When they are filled and labeled they may be set back in the same cases, the covers sealed, or a strong cord tied around it on all four sides. We usually use binder twine for this purpose, as it is cheap and strong. Most of the cases are handled by the cord instead of taking hold of the package. A good man can pack from 30 to 50 cases, ready for market, in a day. Neither time nor expense is required for making cases, and you have something far better for the purpose than you could make.

HOW TO LIQUEFY THE HONEY WHEN IT GRANULATES.

On our labels the following appears: "If this honey granulates, set the jar in warm water or in the sunshine, and it will liquefy."

This is another great advantage in using glass. Sometimes the honey will granulate while on the shelves in the stores; and the clerks know that, if they take it to the rear of the store and set it in the sunshine, it will soon be liquefied and ready to set back on the shelves, so that it is just as attractive as ever.

If desired the honey may be set out in the sunshine as it is packed, and heated up for

a day or two, thereby retarding granulation. If the sun is shining very warm it is better to fasten the covers down before it is set in the sun, else it will become hot enough to melt the comb and spoil the appearance of the honey. If the sun is not shining too warm, the honey can be set in the cases, and the tops left open and set out where the sun may shine on the jars as they stand in the cases. If there is any packing to be done during cool weather, or if any should be left on hand until it granulates, the jars can be removed from the cases and set out in the direct rays of the sun, and then heated up and put in shape for the market.

The illustration shows a large shipment of bulk comb honey out in the sun between our work-shop and packing-house, where it can get the full benefit of the *heat of the sun*. In this way our entire crop of honey is heated so that our trade is troubled but little with granulation.

The apiary in the background is a portion of our home yard, and shows how all our hives are shaded during the summer. We always select a location where there is small growth and thin shade, so that we are not bothered by having to shade our hives, and we have a cool open shade to work in.

Cordele, Ga.

[As we understand it, the illustration shows packages or boxes of bulk comb honey ready for shipment, but placed in the sun for a time to warm up the honey inside. It would seem to us that not enough heat would penetrate through the sides and tops of the opaque packages to warm up the honey in the glass Mason jars so that there would be any effect one way or the other on granulation. Perhaps we do not take into account the full effect of the southern sun.

It will be remembered that Mr. H. R. Boardman and Mr. E. B. Rood have for a number of years practiced setting glass jars or honey in solar wax-extractors, where considerable heat is generated—enough so that the temperature of the honey is raised to a point where granulation is arrested. It is also believed that the sun's rays have an additional chemical effect tending toward the same end. Of course, if the jars are shut off from the sunlight, as in the illustration, there would be no chemical effect.

One objection to bulk comb honey coming to the North is the danger of granulation; and while it can be liquefied, many will not discriminate carefully between what is meant by *warm* and *hot* water, overdo the job, melting the combs as well as heating the honey. In the southern States, where there are no such extremes of temperature

as we have in the North, bulk comb honey would remain liquid longer and in most cases would reach the consumer before granulation set in.—Ed.]

A HOME-MADE PUSH-CAR AND TRACK FOR USE IN A LARGE APIARY

BY C. W. DAYTON

Cut No. 1 shows how I arrange a rack on the Daisy wheelbarrow so as to carry an appreciable load. My frames are 13 inches long, and the barrow will carry 4 comb-boxes, or 8 two deep; but of the standard-size frames the barrow holds 2 comb boxes

side by side, and one crosswise. The Daisy is the best barrow I have ever found for use, either in or out of the apiary. I use a wheelbarrow for wheeling honey until the honey-flow comes on in earnest. Then I use the car constructed as in Fig. 2. I made this car in 1899, and have used it six seasons. The wheels and axles are the same as are used in mining. It runs very easily, carries one or two tons when necessary, and costs \$7.00 for the running gears. It requires about \$50.00 worth of track, made of wood covered with strap iron, as shown.

Fig. 3 shows the loaded car partly inside the extracting-room, and the rear part covered with mosquito-bar frame to exclude bees. I do not run the whole car inside the building.

When the honey-flow is at its height I do not remove honey earlier than about 10 o'clock because the comb-builders are drowsy, and hard to brush from the combs; and I do not remove honey later than 3 o'clock, because the old bees are usually returning from the fields and will fight. But enough can be

removed between these hours to keep us busy the rest of the day and the next morning. The car track is made in 20-foot lengths, and can be put down in an hour or two. When not in use it is piled up and covered with corrugated-iron sheets.

If the apiarist intends to use a car, the ground should be level; and there should be as few directions to travel as possible. My track is arranged in three directions as indicated in sketch 4. When I came here and adopted this location, every foot of the ground was so steep that a hive would roll down the mountain. These tracks are level; and the width of the embankment, including both sides of the tracks, is not less than 12 feet, and affords space for 600 colonies if necessary; but 350 are the most I have kept here. It was made with pick and shovel, which afford the best kind of exercise I know of.

Fig. 5 represents the turn-table, which cost about \$5.00 besides the labor. Fig. 6

shows that the space in the track which the turn-table occupies is too short for the turn-table to turn. For this reason I use the bridge as shown, and give the table plenty of room. My track is made of 2x4 strips of wood, with straps of iron $\frac{1}{4} \times 1\frac{1}{4}$ inches, and

it will carry from two to three tons. Much lighter material could be used, so as to carry 500 to 600 pounds, and cost about \$20 for enough track for 200 or 300 colo-

nies. I would not do without the car, as it enables me to do about one-third or a half more work, and makes work a great deal easier. It is especially advantageous in the height of the honey-flow when every thing goes on a rush and everybody is tired.

The apiary faces the east, so that the bees begin to work early; and the mountains for miles slope toward the apiary, and are covered with some of the best honey-yielding flora. It is also well protected from cold

winds. When the hives are more than 200 feet from the extracting-room it is a little difficult to see the swarms, so I keep queen-guards or traps on the colonies which are furthest away. The canyon is very short. It seldom has any running water in it, although I arranged the ditch for it to run in, in case there should be a cloudburst directly overhead.

Chatsworth, Cal.

DISPOSING OF A HONEY CROP IN A LARGE CITY

BY ALBION PLATZ

To sell honey in a city is an easy matter: first, because of an almost limitless market and demand; and, secondly, because your customers, knowing that you keep bees, have unbounded confidence in the purity of your honey. Bee-hives, to those born and raised in a city, always excite a great amount of curiosity and interest; and to show a few frames of bees and the queen, and, lastly, a frame of newly capped honey to a party of spectators, always invites many sales.

The honey which I secured from my little seven-colony apiary located on Mt. Auburn, a thickly settled suburb about 1½ miles from the heart of the city, is all sold locally and within a radius of four miles. I run exclusively for extracted honey, and have a fixed price from which I never deviate; viz., 20 cts. per pound. I am employed in our local postoffice, and naturally come in contact with a great many people, especially my fellow-clerks, and these are my best customers. Naturally, they tell others about the honey, which they are sure is pure, and thus I have more customers than I can supply. I put up my honey in pint and quart Mason jars, and for the former I receive 35 cts., and the latter 65, refunding 5 cts. for every jar returned.

In marketing honey in this manner, there is no expense for containers, labels, fancy bottles, etc., for it is a well-known fact that a gaudy package often envelopes a very inferior article. No guarantee of purity is ever used or demanded. The buyers see the bees in my garden, and it is a foregone conclusion that the honey is pure. This year I intend to produce some comb honey, as the demand for it is steadily on the increase, and I have many demands for it already, being offered 25 cts. per section. However, I can make a larger profit on extracted at 20 cts., and would rather stick to the latter, as it is easier to produce, and I can secure almost twice as much per colony. I would advise the small beekeeper to run for both comb and extracted, if he has the equipment, and in this way all purchasers are satisfied.

I advise all who have a taste for apiculture, and who have a little spare space in their back yards, even though they live in congested suburbs, to keep a few colonies of bees. There is no better recreation for the city man, and the returns in honey and money always justify the little time and energy spent on the pets.

Cincinnati, May 17.

DEATH OF ISAAC CARTER.

My father, Isaac N. Carter, died May 7, 1912. He had a nice apiary, and was a great reader of GLEANINGS.

Heads of Grain from Different Fields

Bees a Nuisance in Strawberry-picking Time

In conversation with a young man who left his present position to go back to gardening and small-fruit raising, I spoke of beekeeping. He said, "Don't talk bees to me." I asked him why. He said that in eastern Canada where he once worked, a large producer of strawberries, blackberries, and raspberries was located near an orchard in which were about 200 colonies of bees. He said that they did not bother any one until picking time, when the boxes were filled and placed in the shelter of the bushes to be collected. When the collector came along he found the berries covered with bees. Of course, the person collecting the boxes was in danger of being badly stung. Now, what I want to know is, while we have the word of many fruit-raisers and beekeepers that bees will not injure plums, grapes, apples, or peaches, all of which are hard-skinned fruits, have you or any of the contributors to GLEANINGS had any experience with bees and the soft-skinned fruits such as the three berries referred to?

HARVEY G. BRANT.

St. Paul, Minn., April 1.

[It is possible and even probable that, during a dearth of honey, bees might attack overripe raspberries, blackberries, or strawberries, especially if the fruit is bruised in handling. In a case like the one referred to, the beekeeper should make some arrangement with the fruit-grower to induce him to cover all fruit with mosquito-netting as fast as picked. It would take but a moment of time to lift up a cover and place the freshly picked berries under it. It is useless for beekeepers to deny that bees will sometimes attack overripe or broken fruit, especially fruit like strawberries or raspberries. But as a general thing, when strawberries, at least, are in bearing, clover is beginning to yield. When blackberries begin to yield, there is apt to be a dearth of nectar. It is at such times that the beekeeper and the fruit-grower should get together in a friendly way to avert the trouble. It can always be arranged amicably when proper precautions are taken in advance.]

In this connection it is proper to state that bees will not attack sound fruit such as peaches, plums, cherries, etc.; but whenever there is a dearth of honey we always advise having any fruit, as soon as picked, put inside of a building or under a netting. Even if there are no bees around, the fruit should be screened to keep off the typhoid fly, commonly called the domestic or house fly, as that insect can do a thousand times more damage to the human race at large than a few bees on broken fruit.—ED.]

To Avoid Uncapped Cells in Comb Honey

I have been keeping bees for three seasons, and have now six colonies. I should like to go into it on a larger scale if I thought I could make it pay. I am producing comb honey, and the larger part of the sections are not completely sealed over. In some sections, perhaps only one or two cells are not sealed; still, it is enough to drip in handling. I should like to inquire what is the best method of disposing of these sections. I had thought of cutting the honey from the section box and straining and bottling it. Kindly tell me the proper way to do this. Should the honey be heated, or is it bottled cold? I am using eight-frame hives, and mostly plain sections with fences, although I have used beeway sections with the slatted separators, but this does not seem to make any difference in getting the cells all sealed. I use a starter of about one inch in each section.

Ware, Mass.

CHAS. H. WALKER.

[It is almost impossible to get every cell sealed in a section of honey, taking the super as a whole. You will find some, it is true, that are perfectly sealed; but these generally grade as fancy. The No. 1 grade may have unsealed cells next to the wood. There is bound to be a little drip from these cells, but still not so very much either, for the honey becomes very thick in such cells after standing a short time, and is, therefore, less likely to drip.]

If you have a very large proportion of unfinished sections, consisting of those only partly sealed, say two-thirds, it may be that you give too many sections at once. This is sometimes the case when the

new super is added next to the brood-chamber, the one nearly finished being placed on top. The trouble is, that the flow may end suddenly, leaving these upper sections filled but not capped.

There is a plan which tends to do away with unfinished sections, but which requires much more work; that is, to shift the sections from the sides of the supers to the center, removing those in the center just the minute they are finished. Such honey is always whiter and nicer, being freer from travel-stain, and there is much less chance for a lot of unfinished sections at the end of the year.—ED.]

An old Clipped Queen Found Sealed up in a Cell

I discovered a peculiar "stunt" yesterday when looking over a strong Italian colony in a Danzenbaker hive. I discovered twenty capped queen-cells; and, though I looked the frames over several times for the queen, I was unable to find her. Upon cutting out the queen-cells to prevent swarming I found the old clipped queen nicely sealed up in one of the cells. She was in head first. The cell was a very blunt one, away from the other cells, and the bees paid no attention to it. I examined it very closely before cutting it, as it looked rather peculiar, and not one bee was on that cell while I was watching it, although there were hundreds on the comb. The queen was all right about a week ago, and, so far as I know, she was laying at that time. When I pulled the dead queen out she was covered all over with royal jelly.

I wish to mention here that I am a believer in plenty of ventilation to prevent swarming, and these cells are the first I have found in my twelve colonies since 1909. See page 320, May 15, 1910. Some of my colonies have four comb-supers on, all being filled with honey, and there is no sign of a swarm except in this one colony, and this is something unusual.

WALTER T. ACKERMAN.

Huntington, W. Va., May 22.

[A young virgin had probably come from this cell while the old queen was still in the hive, the swarm having been delayed by bad weather, possibly. This old queen, attracted by the royal jelly, very likely went into the cell, and the little hinged door in some way was swung back into place, so that the bees did not suspect any thing wrong, but just sealed it down. Young virgins have been found in this predicament, but we do not remember having seen an account before of an old queen being thus trapped.—ED.]

Veiling Horses when Working Among the Bees

That plan of Louis Scholl's, page 682, of removing loaded wagons from near apiaries or robbers is very good, but a slow way. I used a rope for two seasons ten or twelve years ago, but discarded it for the more simple plan of veiling the horses by slitting an ordinary grass-sack on one edge from the top to within four inches of the bottom. I slip the sack over the horses' heads and tie under the throat with string placed there for that purpose. Then I put the breast-yoke and doubletrees to the team, slip the yokepin on, drop the pin into the doubletrees, and I am off in 30 seconds. As a rule the bees are not bad if horses do not shake their heads. These sack veils eliminate that.

A CAPPING-MELTER THAT FURNISHES STEAM FOR THE KNIFE.

Severin's honey and wax separator, Dec. 15, p. 756, looks pretty good after the whole is once melted, but looks as though it would be slow work melting, besides using too much fuel. It is so open at the top that one would have to have two stoves going to heat this and the knife.

I have one of my own invention that I have used for several seasons that requires only one gas-stove to keep the whole outfit hot. My melting-tanks are double-walled. The outside tank is 16x24, and 18 inches deep, while the inside tank is 14x22x16 inches. At 2½ inches from the top of the outside tank is drawn in even with the top of the inside tank; then both are soldered together, air or steam tight, so that no steam escapes except through the steam-knife, which is attached by soldering an ordinary oil-can spout to the screw top or the place where I put the water in. In this way the honey

and wax are melted and the knife is heated, all with a one-burner gas-stove.

The stuff is melted, then gravity fed into a separator similar to Mr. Severin's. This kind of machine never clogs, as there is a regular honey faucet passing through the outside tank and connecting with the inside one, through which every thing passes as fast as melted. The heat is not only conserved, but the heating capacity is much greater, as the inside tank is hot on the sides as well as the bottom. The inside tank has a partition six inches from the end which has the faucet. In this partition there is a four-inch slip gate to raise and lower, similar to that of the old-fashioned syrup-vats, easy to slip and unclog if necessary.

Of all uncapping devices, the steam-knife, in my opinion, leads. When some one says that he has a machine for uncapping honey, and I find that the machine does not save the wax, then I fail to get interested. A machine that does not save the wax has no place in my apiaries. Show me the man who has 500 colonies who will give me the wax for extracting his honey, and we will make a deal at once. With the steam-knife one gets all of the wax besides leaving the comb in fine shape. I can take my steam-knife and shave cells down level when there is neither honey nor cappings on them, opening the cells without destroying the cell walls, and can take off a sheet of wax merely hanging together by the cell walls, resembling a queen-excluder.

Mr. Crane, page 680, Nov. 15, says that stirring honey undoubtedly makes it candy more quickly. My opinion is the same, therefore I do not take well to the honey-pump, much discussed of late. It's my opinion that, the less one handles white nectar, the better the quality and flavor. For example, take two nice white combs of honey, extract one in the extractor, and just slash the other with a knife. Let the honey drain out, then taste the samples.

Pasadena, Cal. J. F. CROWDER.

Carbolized Cloths an Aid in Taking Honey off Rapidly

I use crude carboic acid, sprinkling it on 4 or 5 cloths, and put them on as many hives. As soon as one is taken off it is put on another so as to have them all covered, and to give the bees time to go down. Very little bruising results, and the honey can be taken off faster than by any other method that I know of.

QUEEN-EXCLUDERS WITH THE SLOTS RUNNING CROSSWISE.

There is much talk about queen-excluders. Some are for and others against them. I am for them, and would not produce extracted honey without them, any more than I would run a dairy without a cream-separator. When the bees get strong I place the brood over the excluder and give the queen below some empty combs to lay in that keep her satisfied, and there is no swarming to bother with. My excluders are all zinc. They are the full size of the hive, outside dimensions, and the holes are made crosswise, thus giving the bees a chance to get through anywhere. There is no danger of breaking the excluders as with the wood slatted ones that hold together only a few years.

When are we going to have that wired foundation? It seems to me that is the only thing needed now. If we could get wired foundation up and down in the frames, and then put wires in ourselves lengthwise, we would get some perfect combs.

Brush, Colo. DANIEL DANIELSON.

If the Middleman is Cut Out, the Cost of Selling is No Lower

The middleman is not in the way. He really is necessary. Without him there would be no market prices. If there were no middleman it would affect the farmer more than the honey-producer. The farmer's time is all taken up. He has no time for other business; and if it were not for the middleman it would be necessary for him to sell the produce that he raises on the farm, and he would be obliged to deliver it from house to house. If he has some beef to sell he must first dress it; then sell it by the pound from his wagon. If it is in the summer he must have ice, etc. Suppose it takes him two days a week to sell and deliver his produce. He must then hire a man to take his place on the farm, or to sell and deliver his goods; but he can not hire

a man for two days a week. He must be engaged by the month or year, and must be well paid in order to keep him.

There is no market price. Every producer sets his own price, which must more than cover the cost of the hired help. As a result the consumer pays as much or more for his eatables than he does now with the middleman. The hired help is the middleman in the case mentioned. Every farmer must do the same thing, and some of them can sell more cheaply than others. The result is easy to see.

Suppose one is several hundred miles from a large city. The home town will soon be supplied. Then produce must be shipped to the city, and there must be a man there to deliver it to the consumer. There is always a middleman for the large producer. The small producer can produce and sell his own crop of honey, etc., with profit; but there may be more profit for him if he puts in all of his time as a producer and sells at wholesale prices.

Any article that does not spoil, such as honey, can be sold by advertising in newspapers and magazines; but the newspapers and magazines are really middlemen, as they are between the producer and the consumer, and they must be paid.

A mail-order trade may be all right, but it also takes time and money to get the trade. No doubt it would take twice as much time and money to get the trade, with every producer selling, by advertising in the papers, and through the mails, etc. Parcels post would be all right, but in time the mail-order houses would get all the trade, and then they would raise their prices.

The mail-carrier would have to have a team of horses and a dray wagon to deliver the goods, and double the pay that he gets now; and then he could not make as long a trip as she does now. Parcels post may not be as cheap as it seems.

The need of a class of distributors must be recognized; but we must demand it, and a condition will come when these distributors will be more closely associated with us as producers, for co-operation will extend the terminal markets.

Greenville, Wis.

EDWARD HASTINGS.

Selling Honey by "Talking"

I believe heartily in the value of advertising the food properties of honey. I began the production of honey four years ago by buying 53 colonies of bees. Up to that time I had never, to my knowledge, been closer to a yard of bees than a city block. I now have 180 colonies. In 1910 from 100 colonies I produced 11,000 lbs. of honey—extracted exclusively. This I disposed of in my home market, a city of 18,000, at 15 cents per pound net. Up to the time I introduced extracted honey here, comb honey was the only kind ever seen; but now the demand for my goods is greater than I can supply. My honey retails here at present at 60 cts. per quart jar. To create this demand I have had to keep myself and my bees before the public by any means that I could command. I have displayed my extractor at our local fair, lectured on bee life at churches, and talked honey at every opportunity.

In order to interest Canton College I donated them 120 lbs. of honey to use in their "Domestic Science" course, and it occurs to me that the honey-producers in the other parts of the country can find this a sure means of getting the food value of honey taught, not only to the students but in the homes to which they will go between school terms. It will be necessary to teach the teachers themselves, as I find that this subject is one upon which they are woefully ignorant; and it seems to me that it's up to the honeyman to show them the light.

Ogdensburg, N. Y., Dec. 20. W. T. DAVIS.

Carbolic Cloths do Not Kill Brood

In Stray Straws for April 1 Miss M. Candler is reported as having used carbolic cloth largely, and it did its work well, but killed brood. Although I have used these cloths under all circumstances I never have known them to do that. I am well acquainted with some of the best beemen in Carmarthen, South Wales, and I've never heard a word concerning the killing of brood, nor have I ever seen a hive where it failed to do its work when used in the right manner. I myself have great faith in it, and shall always use it, when necessary, in preference to the smoker.

R. V. HEYHOE.

Toronto, Ont., Canada, April 20.

Our Homes

A. I. ROOT

Even Christ pleased not himself.—ROMANS 15: 3.
 Even the Son of man came not to be ministered unto, but to minister, and to give his life a ransom for many.—MARK 10:45.

The character of our Lord Jesus Christ stands out clear and sharp as differing from that of any merely human being who ever lived. As described in our text, "he pleased not himself." In fact, the more we study the account of the life he spent here on earth, the more we are impressed with the fact that he never used his wondrous power in any way for his own personal benefit. He never thought of self. Even when wearied by days of busy toil he never seemed to think of either rest or refreshment. The accounts we have of his taking food, or most of them, seem to be incidents where he taught some lessons by the partaking of food. He once convinced his followers, after his resurrection, that he was still flesh and blood by eating with them. When thirsty after a long travel, and he met the Samaritan woman at the well, he apparently forgot his thirst in leading her up and out of her wretched condition so that *she* might partake of that "living water;" and when his disciples, after they had brought food and urged him to partake, he replied, "I have meat to eat that ye know not of."

This whole matter was brought vividly to my mind by an address delivered by the Rev. Joseph Clark, in Columbus, at the Congregational State conference a few days ago. In his excellent and soul-stirring address he said something like this:

"My little girl came to me a few days ago and propounded the question, 'Papa, can we be happy *always*?' "

He said he studied over the matter a while before he answered a question of so much moment. After a little reflection he replied:

"Yes, my daughter, we *can* be happy *always*."

But immediately she propounded a question of still deeper and of more vital moment. It was this:

"Papa, I am not always happy. What is the trouble?"

Before answering her he meditated again—perhaps more deeply than he did before; but he finally replied:

"My daughter, if we are always busy in trying to make somebody *else* happy, we shall be happy; and it is the only way to live and get *real* happiness."

Now, my good friends, you who read these Home papers, let me put the question

to you—are *you* always happy? Suppose I should ask all of my readers who are *always* happy to raise their right hand. How many hands would I see? Suppose I should ask again, "How many of you are happy a part of the time?" I hope every hand will go up. But if I should ask, "Is there one among you all who is *never* happy?" may God forbid that there should be even *one* such person! When a poor child of humanity says he is *never* happy, he is coming pretty close to the terrible suicide mania that is now cursing our world of people more or less. Perhaps there are some among you who are *seldom* happy. My good friend, the trouble is *surely*, as Dr. Clark put it, because you have been seeking happiness from a selfish point of view. You have got it into your head that the world owes you "happiness," or, say, that it owes you a *living*, whereas the world really owes you nothing; but *you* owe to the world a big lot. "Not to be ministered unto, but to minister."

Some of you may turn around and ask the question, "Mr. Root, are *you* always happy?" I answer frankly, "No, I am not always happy; but when doing my duty, working honestly and unselfishly for the great sea of humanity around me, there is an undercurrent of happiness that is seldom or never very *much* interrupted or disturbed."

I can always thank God for having given me a human life to live; and whatever trials or temptations or disappointments and perplexities meet me, I can, *thank God*, say honestly and devoutly, "I *know* that my Redeemer liveth."

I have told you in former Home papers how that little prayer, "Lord, help," often lifts me up out of darkness and into the light; and when a contrary and stubborn spirit seems to get possession of me, I involuntarily breathe that celebrated prayer of David, after he had sinned and fallen—"Create in me a clean heart, O God, and renew a right spirit within me."

Now, we have been discussing so far, at least mostly, our spiritual experiences. I find that, as I grow older, and, in fact, all through my life, to be happy and enjoy life I must take care of my physical body. Of late I can not stand office work or reading papers and magazines much more than an hour at a time. I have, hanging up right handy, near the back door a very light and bright shining hoe. Whenever I am done

using it I rub off the clean steel blade so that it fairly shines. Well, two or three times a day I take this hoe in hand and work in the garden until the perspiration starts, or until I feel a little weary. Then I stop and greatly enjoy a good drink of boiled rain water. I do not care to have it ice-cold; but I try to keep my enameled pail of drinking water in the coolest place about the house, especially in hot weather.

Some of you may suggest that getting happiness by using that bright hoe is working for self, and not quite in line with what Dr. Clark said to his little girl. But, my good friend, there are many ways of using a "bright sharp hoe," where it is not all self. The children and some of the grandchildren have gardens around our home; and I frequently use this particular hoe to teach them lessons in gardening. A few days ago I said to my youngest daughter, "Carrie, your tomatoes need hoeing. I will hoe just one row for you for a pattern."

She thanked me; but another daughter, "Blue Eyes," who was near by, looked up with a roguish twinkle in her eyes and said, "Father, I wish you would hoe one row of our tomatoes too, just for a pattern."

I assured her it would give me great pleasure to do so. Now, Carrie's tomatoes were in a little bed of three rows, with four or five in a row; but when I started to do some more "sample work" I found Mrs. Boyden's tomatoes were all planted in one long row clear across the garden. You see they "had a joke on father."

There is another way in which that bright hoe comes in play in the line of our texts. By its use I raise considerably more garden stuff than Mrs. Root and I alone can take care of; and one of the rare pleasures of having a garden is where you have a little surplus (or perhaps if you have not) of carrying samples around to your neighbors, and surprising them in two ways—first, by the excellence of your skill as a gardener; and, second, your disposition to *divide* with your neighbors the good things that God in his mercy has given you as the reward of your toil.

I have been studying over this matter of being happy always, for same days past, and I have been trying to think of some one person who seemed to be happy always. The one who came nearest to it was my good mother—bless her memory! From early childhood clear up to old age she seemed always bright and cheerful. The one text I have quoted, "I know that my Redeemer liveth," was one she quoted often. Whatever happened to make the rest of the family feel sad and sorrowful, she always took a bright view of the case. Her whole

life reminds me of a beautiful thought expressed recently in the *Sunday School Times*.

SINGING ALWAYS.

Nothing can quench the song of a heart that really believes in the love and power of God, and that has accepted this in Christ forever. If the song is quenched, it is because we have, for the time, ceased to believe in God's love or power; but that we need never do. As Victor Hugo wrote:

Be like the bird, that, halting in her flight
A while on bough too slight,
Feels it give way beneath her—
And yet sings—
Knowing that she hath wings!

Our wings are the love and the power of God in Christ who is our life. Nothing can overbear these wings; nothing can deprive us of the joy of the consciousness of their presence except our own refusal to let Christ share himself fully with us. And even that refusal Christ can overcome, if we honestly ask him to do so. His joy may be our joy, always. Everything else may give way beneath us; but Christ, never. Therefore "I will sing with the spirit, and I will sing with the understanding also," and all the powers of earth and hell shall not quench my song.

The reason why the bird mentioned in that beautiful stanza kept on singing, even though the slender bough gave way when she alighted on it, is because she "had wings"—wings that never failed, and which would always buoy her up. My mother's life always seemed to have the comforting and sustaining assurance that there were wings out of sight that would always prove a "present help in time of trouble." My good father, however, who, although a professing Christian, and who finally died trusting in the Bible promises, had his ups and downs. He used to get what we called in olden times the "blues;" but mother's bright and cheerful face was *usually* a never failing remedy. I have often thought that it was providential that they two were brought together. At one time in his life, during a quarrel over a division fence, he talked about withdrawing from the church, and said to our good pastor that he would have withdrawn long before had it not been for his "companion." The pastor replied something like this:

"Brother Root, that devoted 'companion' of yours, if you will continue to be guided by her, will ultimately bring you into the kingdom of heaven."

Now, my friends, let me exhort you, in closing, especially if you want to thank God and enjoy every moment of your life, to be always *busy*. Have a bright clean hoe like mine; and whenever you feel that streak of unhappiness coming on, get busy with the hoe; and when you get busy, remember what good Dr. Clark told his little girl. Be contriving and planning and working, or experimenting in something to make *others* happy; and before you know it or realize it you will be happy yourself, and singing like the bird on the swinging bough.

There is a beautiful promise in the 91st Psalm which I think will make an excellent ending for my talk on happiness.

There shall no evil befall thee, neither shall any plague come nigh thy dwelling. For he shall give his angels charge over thee, to keep thee in all thy ways. They shall bear thee up in their hands, lest thou dash thy foot against a stone.

JUDGE LINDSEY, OF THE JUVENILE COURT OF DENVER, AND THE WAY RIGHTEOUSNESS

IS PROSPERING OVER INIQUITY.

Mr. E. R. Root:—Perhaps you have seen it in the papers; but I want to tell you that the corporations have been thrown out of politics in the election in Denver. This is the culmination of the fight begun several years ago by Judge Lindsey, the story of which is told in "The Beast and the Jungle." The victory was so sweeping that every office was captured by the Citizens' party headed by former Assessor Henry J. Arnold, who is now Mayor, and Judge Lindsey, who is still Judge of the Juvenile Court. Judge Lindsey ran over two thousand votes ahead of the Citizens' ticket, and the Citizens' ticket polled about 41,000 votes against about 30,000 for the Republican and Democratic tickets combined.

You remember that I told you about the assessor being thrown out of office by force at midnight? Well, he is now mayor. The reason that he was thrown out of office by force was because he would not extend an illegal tax levy upon the assessment rolls.

Another thing was the fact that the former machine administration would not call a special election to vote on commission form of government, petitioned by over twenty thousand voters. This is provided for in our initiative law, but they disregarded it, and are now supplanted by officers, every one of whom is pledged to commission government.

Why not ask the readers of GLEANINGS to express themselves on their choice for president, also on government ownership of telegraphs, express companies, also any other public questions of national concern?

I am enclosing a letter, the fourth during the past month from different GLEANINGS readers who have invested their money with this man Degge, who is a promoter of a score or more of enterprises, not one as yet a dividend-payer. He has had fraud orders issued against him several times, I believe. Our local banker referred to his schemes as thirty-cent propositions. What can GLEANINGS do to get these people to write to me *before* they invest, and not after?

Boulder, Colo., June 2. WESLEY FOSTER.

May God be praised for the good work that is going on in Colorado. And, by the way, it may save somebody's honest earnings by presenting also the letter you mention.

Mr. Wesley Foster:—Would you kindly give me some information regarding the enterprises in which W. W. Degge is interested, in and around Boulder? Do you consider him thoroughly reliable? I am a stockholder in his company, and should like to know your opinion of his chance of making good. I am an old beekeeper, and have invested my earnings with him, and should like to know through a fellow beekeeper his standing in the community in which he lives. I have been reading your letters in GLEANINGS, and felt that I could rely on any information you could give me regarding M. Degge.

Appalachicola, Fla., May 20. W. P. DUNLAP.

Just think of it, friends. A hard-working beekeeper, and one also, as we take it, well along in years, has wasted his hard earnings by listening to some wild schemer and promoter. Every little while we hear of somebody who has toiled hard for years with poultry, bees, or market-gardening, and then is duped out of it all by some

schemer. Is it because so many are crazed to get a *bigger interest* than they can get at their bank, or, say, of their near neighbors, where it would be perfectly safe? Once more, do not think of investing money with *anybody* who talks to you about "dividing his profits," "profit-sharing," etc. And, above all, write to somebody *you know* and can *trust* before you think of "investing" *any thing, anywhere*.

ST. CLOUD, FLORIDA, THE HOME OF THE OLD SOLDIERS, ETC.

Mr. A. I. Root's attack on Florida, and St. Cloud in particular, is unwarranted and not sustained by facts. I visited St. Cloud recently, and met and talked with a score of citizens picked at random on the streets, and I found them all happy and contented. I noticed that not many of them were trying to cultivate the soil, but they were getting fullest enjoyment out of life. St. Cloud's population, as you state, is composed of old soldiers. My father is an old soldier. He enlisted in the 144th Ohio. I brought him to this State three years ago. I located him at St. Petersburg because there were quite a number of G. A. R. men there. If I had known about St. Cloud at that time, or had investigated any of the other soldier colonies in the State, I would have located him among his old comrades. My father is too old and feeble to work. I suppose that 80 per cent of the soldiers at St. Cloud are too old to get out in the sun and plow and dig and harvest. I did not expect my father to work; but I did want him to enjoy the declining years of his life down here in this sun-kissed country where he could get out his fishing-rod and spend hours on the shores of the bay; to sit on the threshold of his home, and, as the last lingering rays of the sun tinted the skies into glorious hues, smoke and ruminate, and retire with the peace that on the morrow it would be another day without care.

And at St. Cloud you will find other fathers and other mothers, bent with age, and with worry of other days, crippled with rheumatic pains, some palsied, some pitifully crippled, who are thanking God that they are down in Florida, away from the extreme cold and the extreme heat, where a generous government's bounty is sufficient for their small needs. I know what I am talking about. I know of a mother who spent eight months of each year inside of a superheated home, and of a father who suffered hemorrhages, and was thrice given up to die. These two people were brought from Ohio to Florida, and that mother to-day spends every day of the 365 out of doors, feeding and tending to her flock of chickens. She in three years has become twenty years younger; and that father is taking on flesh, and now laughs at the doctors, when before he was in fear of them. Is not that worth more than money? Is money every thing? Can you not talk Florida without measuring it in dollars and cents?

Suppose your brother-in-law had a brother who bought a piece of property, as you say, for \$100, and was offered \$400 and refused it, and is now sorry he did not sell because he can not get an offer of \$100 for it. Does that signify any thing except that he was grasping and greedy? He wanted more than \$400 for the \$100 lot—may be \$600 or \$1000. He took a gambler's chances; and because he did not win out he is a welcher. He is kicking that the game was not played fair.

Those who bought a \$100 lot, and improved it, and caused vines to grow about it, and oleanders and hibiscus flaunting their colors in front of it, and fruit trees in the rear yard, under which a flock of chickens disport, would not sell for \$1000 or may be \$2000, because it is home, and in that home there are health and contentment, and every morning begins a fresh day.

I am not going to answer your general attack on Florida nor that on St. Cloud. You can see a malignant spirit in all of it. I am simply writing to you to show you another view-point of the old-soldier life in Florida, and I trust you will give this article the same prominence you did the unwarranted attack.

As I write a man brings me a photograph of a

mound of watermelons on his place. This man was a traveling salesman out of Cincinnati. He came here seven months ago and bought ten acres of second-class pine land. He grubbed it and cleared it. He told me that he had sold \$1300 worth of melons off the tract, has two more carloads to ship, and has set out a ten-acre grapefruit grove. He said he made more money, and had more fun in the six months' residence in Florida, than a year's hard work "on the road." And this is land which you are abusing. This man mixed some Ohio brains with the soil, and that will grow any thing in Florida except *Presidents!*

Tampa, Fla., June 6.

W. B. POWELL.

My good friend, we submit your letter to our readers as you request, and I would submit the matter to them as to whether you or I show a "malignant spirit," as you put it. If you have been reading GLEANINGS right along I think you must agree that I have been giving both sides of the matter pretty fairly. What you say about old people getting a longer lease of life, comfort, happiness, etc., I believe is generally true over nearly all of Florida; and may God be praised that we have at least one State in the Union where we are comparatively free from frost and snow. But at the same time you have not explained to our readers how the St. Cloud syndicate justify themselves for paying 80 cents or \$1.00 an acre for land, and then selling it to the old soldiers for \$20.00 or \$30.00 or *more* an acre.

Perhaps I might suggest to our readers that, as secretary of the Board of Trade of the beautiful city of Tampa, your opinion and ideas may be somewhat biased. I am glad to see people stand up for their own State, town, and county—yes, and for their own neighborhood; and I am well aware that large numbers of my Florida friends are pained and sometimes vexed at me when I mention such trifling things as redbugs, long dry spells, damaging frosts, etc. Well, I am trying hard to give our readers, now scattered in almost all nations of the earth, the *real truth* about every spot on the globe.

ST. CLOUD, FLORIDA, AND SOMETHING ABOUT IT AS A HOME FOR BEEKEEPERS.

The following, clipped from the St. Cloud *Tribune*, explains itself:

G. A. Bleech came here two years ago in January from Hillsdale County, Michigan, where he was engaged in the bee business. His health then being poor, he decided to try Florida to see what the climate would do for him. When he first came he brought with him three high-grade queen bees, and from them has 12 colonies. They are doing well, and he expects to fill his hundred hives without trouble. He thinks this an ideal country for honey-making. He has experimented enough to satisfy himself that he can do better than in Michigan, with flowers every month; and with orange, peach, and magnolia blossoms in season he says as fine honey can be produced here as anywhere in the country. It requires care and watchfulness and work, he says; but that is true of any industry if a man expects to succeed. Mr. Bleech says his health is all he could desire, and he's here to make this country his home. He is incensed at A. I. Root, of GLEANINGS IN BEE CULTURE, who seems to take pleasure in saying ill-natured things about St. Cloud, writing

to his publication at Medina, O., from his winter home at Bradentown, Fla. Mr. Bleech asked the *Tribune* to reply to an article in the May issue of GLEANINGS, but life is too short. This is not Mr. Root's first offense; but St. Cloud is growing, and will keep on growing, in spite of Mr. Root and other grumblers and soreheads. Mr. Root likes Bradentown, but doesn't like St. Cloud. Mr. Bleech doesn't like Bradentown, but likes St. Cloud. And there you are. We are glad Mr. Root likes Bradentown, if he does; but a man who is everlastingly trying to control the affairs of the universe is a pretty hard man to be suited anywhere.

As I have remarked before, our good people in Florida, as well as in other localities, do not like to have any thing said (especially in print), against their own town and locality. I *do* like St. Cloud; but I *do not* like the idea of charging old soldiers thirty or forty dollars an acre, or ever so much more, for land that cost the promoters only eighty cents or a dollar per acre. Our good friend Bleech has been only a short time in St. Cloud, as I take it; and I think he will soon discover that neither in St. Cloud nor in any other place in Florida, are there flowers enough to produce honey, to amount to any thing, "*every month in the year.*" During the past season my neighbor Rood, with several hundred colonies, has secured so little honey that he is just now wanting to *purchase* some in order to supply the demands of his regular customers. Once in a while we have a season when Florida gives wonderful crops of honey; but, like almost all other localities, so far as I can learn there are also seasons, or special times during *every* season, when bees will starve unless they are fed. If I am not right in regard to the above I wish the veterans in the bee business would correct me. I do not believe it is true that I "take *pleasure* in saying ill-natured things" about St. Cloud or any other place.

EXAGGERATED STATEMENTS IN REGARD TO FLORIDA, ETC.

On page 356, June 1, I gave a letter protesting against our accepting certain advertising from the Seaboard Airline Railway. I made a clipping of this and forwarded it to headquarters of the S. A. L., Norfolk, Va. Below is their reply; and as it gives some valuable facts I publish it entire:

Mr. A. I. Root:—This will acknowledge receipt of your kind letter of June 10, accompanied by some criticisms on the part of Mr. A. W. Foreman, Whitehall, Ill.

The land area of Florida is 54,861 square miles; and while the correspondent has doubtless been in Florida, his article would indicate that he did not spend sufficient time to investigate conditions in so large an area. The result of the efforts of Mr. Root is a complete answer, and can be multiplied many times by individual instances in the Manatee section. We do carry an advertisement in the *Rural New-Yorker*, and read that valuable journal regularly. Mr. Foreman refers to the entire area as being sand. The 54,861 square miles in Florida

exceeds the area of Pennsylvania. It would probably be just as correct to say that all of Pennsylvania was coal land. The Manatee book and the developments of the Manatee district have been most carefully selected, and they do not tell of the maximum possibilities of intelligent and careful agricultural methods under the best conditions in that section, as we used the most conservative method. Mr. Foreman would doubtless be surprised to know that the Palmer interest, who already have a very large interest in Manatee County, have recently purchased 680 acres of land just south of Bradentown, the consideration said to be \$23,000, or nearly \$40.00 per acre. Land to bring this sum must have value, and it was sold to people who already have an interest in the landed area of that section. Another Illinois citizen is reported to have purchased 250 acres in the Manatee district for the purpose of developing citrus groves. Price is not reported; but the location of the property leads us to believe that it was no small sum per acre. If

Mr. Foreman will take the United States census records, showing the almost marvelous increases in the population of southern Florida, Manatee County especially, for the past ten years, I am satisfied he would have a better line of information on the State than now appears to have reached him.

Norfolk, Va.

J. A. PRIDE.

It is quite a joke on our good friend Foreman that the *Rural New-Yorker* does carry the advertisement of the S. A. L., although it may not be exactly the advertisement that friend Foreman refers to. I happen to know quite a little about Mrs. Potter Palmer's purchase, for it is right close by the "Robinson Crusoe" island where I spent two winters.

Poultry Department

STODDARD'S CONVERGENT POULTRY-YARDS

How Many Miles can a Hen Travel in a Day? or, if you Choose, How Many Miles does a Hen Travel in a Day? and, Finally, How Many Miles can a Hen Travel in a Day Without Impairing her Egg Record?

Some of you who have not considered the matter may say a hen does not travel even one mile; and may be you will add that, if she is to make a good egg record, she ought *not* to travel half a mile. Philo, you know, has been trying to teach us that a hen will lay more eggs, if she does not travel at all, than if she has the run of the farm. He would, however, dig up the ground in her little pen, and bury in it some grain so as to induce her to do work that would probably be the equivalent of quite a *little* travel.

Some years ago I visited our good friend Hunter, at Seven Mile, Ohio. He is the great seed-corn man, you know. His dwelling is set on a very pretty little hill or mound. The ground slopes away from the house in every direction; and corn-growing has been so much of a hobby all his life that his cornfields come clear up to the house in every direction. As fences would be in the way, so far as I can recall he has none. The men start out from the barn near the house with a team in the morning, and go off cultivating half a mile or more in every direction, doing something useful, "going and coming." Instead of going through a long lane to get to their work, their work *commences* right at the stable and then *ends* at the same spot. Well, friend Hunter has a lot of chickens. They pick up their food while roaming through the cornfields, following the plows, picking up grubs, etc., and earning their living in many ways besides the eggs they lay.

Do you ask how he can have any garden without fences? Well, he endeavors to have his garden so far away that the chickens will not get up to it. When I was there he had a beautiful garden nearly a quarter of a mile from the house; but some of the most enterprising of his poultry had found it and "got there" after all. I think I never saw a handsomer or healthier lot of chickens. They just crowed and cackled and rejoiced from early morn till dewy eve—chickens little and chickens big; and I believe that he or his good wife or the children always have excellent "luck" with chickens, while a neighbor who had all modern appliances, including lamp-heated brooders, had dead chickens by the score. At the same time that friend Hunter's chickens were going everywhere in the field, this neighbor had his chickens shut up, and lamps burning to "keep them warm" so they could not "catch cold." Pardon me if I am telling this story over and over again, for it is one that can not be told too often nor with too much energy and vehemence. Mankind all over the world are spending money in building air-tight houses in order to avoid drafts and catching cold, when plain common sense ought to send them outdoors into the fields, where they can get health and strength by digging and scratching for a living. I am talking about chickens and people both.

Well, perhaps you would like to know what I am driving at. Suppose a laying hen can walk a mile or half a mile, and still do a good job at laying eggs. What of it? Well, I am proposing that this same laying hen shall run errands and help earn her own living as well as lay eggs; and I hope she will lay *more* eggs while she is doing errands and saving her owner steps. I have not yet got around to the point where I can send her to the postoffice, grocery, and other

places, but we may accomplish it after all. As I said, I do not exactly expect to have her carry her eggs to the *grocery*, but I do expect to have her bring them up to the *grocer's wagon* instead of having her owner travel around to the nests to pick up the eggs in a basket. Let us now go back a little.*

As I told you on page 578, Sept. 15, 1911, between thirty and forty years ago I was greatly excited in consequence of a series of articles in the *American Agriculturist*, entitled "An Egg-farm." The writer was our veteran friend, H. H. Stoddard. He had planned to have poultry-houses located all over the field—I think about ten rods apart. They were arranged like the cells of a honeycomb. A low-down wagon went to each house, carrying water and grain, and to gather the eggs, etc. I started such an egg-farm in our basswood orchard at the time it was planted, in 1872. I soon decided, however, that one objection to Stoddard's egg-farm was the amount of travel incumbent on the owner in order to keep things in running order. Well, this

* Our stenographer suggests that I, unlike Mohammed, who, being unable to bring the mountain to him, concluded to go to that, have solved that problem by bringing the chickens to me instead of being compelled to chase after them to feed them and gather their eggs.

Fig. 1 shows Stoddard's convergent poultry-yards. As will be noticed, it pictures 16 yards converging to the center, where the granary is located. The engraver has outlined 16 poultry-houses adjoining; but in Florida and Texas I do not think these houses will be needed. In fact, H. H. Stoddard, the inventor, of Riviera, Texas, has 600 fowls in yards, as above, roosting in the open air, without any roof over their heads at all. I do not know at present how he protects the food-hopper and the nests.

same Stoddard is now down in Texas superintending an up-to-date (or we may say 1912) egg-farm; and in place of going around to the different poultry-houses with a horse and wagon he makes the laying hens do the running. Before I saw that friend Stoddard had got the idea of it, it had been running through my head, off and on, for years.

SOME PLAN OF TAKING ADVANTAGE OF THE DISPOSITION OF MANY OF OUR BEST EGG-LAYING TRIBES OF FOWLS; THE DISPOSITION TO ROAM AND RAMBLE.

I had planned to have four or perhaps eight yards all running down to a common center, where the nests, watering-troughs, the feed-pans, and the roosts were to be located; but friend Stoddard has "outgeneraled" me by having his arranged like the spokes in a wheel—say of a wagon or buggy. The circle in the center, or where the hub of the wheel comes, is to be large enough to include a granary. The spaces between the spokes of the wheel are the separate yards. I think he has sixteen yards, with the granary in the center. This granary had, perhaps, better be a round building, say something like a silo. A lane gives access to this inside circle, 45 feet in diameter, which he describes in the *American Poultry Advocate*

for May. A team can come in with a load of grain and go right around the round granary, then go out again. This "inner" circle or fence is 45 feet in diameter, and with sixteen yards each yard would occupy a part of this smaller circle, about ten feet across. The division fences ought to run out far enough to give yard room, say for fifty hens in each yard. If the fowls were not too much disposed to get too far away from where the feed, water, and nests are located, he might leave the outside ends entirely open so a team, a harrow, or any other farm implement could be driven from one yard right to another without opening gates so as to grow corn, for instance, in each yard as Mr.

Hunter does, or, if you choose, grow potatoes. Down in Florida the chickens would dig up and eat a good lot of the potatoes nearest their house or home; but I do not know but potatoes or something equivalent would be a cheap way of furnishing them with green food. Have a field big enough so as to give them all they want, and *still* have some left. Very likely it would be wisdom to have a fence or some gates so as to keep them off the crops, if need be, until they are well started.

In Texas, where my friend Stoddard has his up-to-date egg-farm, the weather is so warm (as it is in my Florida home) that he declares no roof is needed over the roosting-places; and after having tried this plan for two winters they do seem to do about as well without any shelter. As they, however, seem to *prefer* to run under shelter when we have heavy rains, I think I would have a roof for each pen that would give comfortable shelter to fifty laying hens in each yard. For nests we will have boxes with a sloping roof, or, rather, a hinged cover for a roof—coming inside of the inclosure around the granary. Friend Stoddard has sixteen yards, as I have told you, all running down to one narrow center. With fifty hens in the yard this would make 800 on the egg-farm. But one yard would be occupied by the lane running down to the granary, or at least the lane would take up a considerable part of it, and another yard would probably be saved for sitting hens, and possibly two or more yards for chickens of different ages.* This would leave

Fig. 2 shows my modification of Stoddard's convergent poultry-yard. You will observe, however, that I have only 8 yards instead of 16, and I have 4 poultry-houses, each 8x16, divided in the center by the wire netting so as to make 8 roosting-places 8 feet square. These roosting-houses have a shingle roof at present, with doors so arranged that all the poultry can be securely locked up nights. The granary is so arranged, as you will notice, that the feed may be carried from the store-bins to the feed-hopper only a few feet away; and that is also arranged so that one roof will answer for the two yards, and the feed-hopper is located right in the division fence so that one hopper feeds two yards; therefore you will observe that 4 hoppers answer for 8 yards. In like manner four series of nests answer for the 8 yards, and also, in like manner, 4 feed-hoppers, and 4 watering-dishes, or troughs. I have not thought it worth while to show the watering-arrangement either in the cuts or diagrams.

twelve yards to contain fifty laying hens each, or 600 laying hens in all. Well, friend Stoddard tells us in the *Journal* that one who has had practice with such an arrangement can feed the 600 fowls in *one minute*, and not have them all crowding and getting their muddy feet in the food, etc., either. The watering arrangement is simply a dish into which water is constantly

* In order to get the proper number of pullets for our "egg-farm," we shall have to raise about an equal number of males; at least there is no way as yet for helping it to any great extent so far as I can learn. Well, we are frequently told that the sexes should be separated about as soon as we can

distinguish the cockerels, and we want a separate yard for these. With my arrangement of fences and yards down in Florida my cockerels were so far away that they sometimes got neglected; and if you want to sell them for broilers or "fries," as they call them in the South, they need to be crowded with the best kind of food and care. Well, just think of the saving of time and labor in having these "young roosters" (like all the rest) come right up to the granary for food, water, grit, shells, meat, or whatever else you choose to give them.

dropping, and they are so arranged that each dish will water two yards. For fifty laying hens there ought to be about half a dozen nests. You will probably never get over forty eggs a day, even when they are doing their best, and this would give seven eggs for each nest. Down in my Florida home I frequently have ten or eleven eggs laid in one good-sized nest—sometimes a dozen. These nests can be made in long boxes of a dozen each, set right across where the partition fence comes—six nests on one side of the partition fence and six on the other.

When it is time to take the eggs to market, a light wagon or auto (as you choose or can afford) simply runs around the granary and picks up the eggs and they are loaded for market in five or ten minutes, or may be less. Grit and oyster-shells, as well as water, are furnished in the same way. Green food, grass, and insects, the fowls get by going out on their free range, giving them a narrow yard, or perhaps a three-cornered yard, an eighth of a mile long if you can afford it.

You may suggest that they will lay in the bushes rather than in the yard. After testing the matter for half a dozen years I find that my strain of Leghorns and Buttercups as a rule *prefer* to lay in a pleasant and convenient nest under shelter rather than to go out into the bushes. The pullets, when they begin to lay, sometimes will steal a nest or drop their eggs on the ground; but they soon get over it, and get over to where the other hens lay. If you decide that you want their roost placed under shelter, a shelter or double roof can be easily fixed across one of the division fences, so as to make your open-front house cover two yards. In this case, if you sweep up the droppings under the roost every morning, as we have been doing every morning for two or three years past, very little time

Fig. 3 shows about the plan I have decided on for nesting places. I am sure it is best to give the fowls a secluded nest, free from interruptions, and where they will not be frightened by visitors who go through the yard; and if egg-eating should get started I would have the nests so that they can be made quite dark. The engraver has made a part of the nest-boxes of wire netting. This will be especially desirable in hot climates like Florida and Texas. I prefer to have the nests up, say, 2 to 2½ feet from the ground so as to avoid the necessity of stooping over.

is required. If you do this, I do not think that, as a rule, you will be troubled with vermin of any sort. By the way, I would have this "inner court" around the granary *absolutely* secure from rats, mice, skunks, or other prowling nocturnal visitors. Until this last season I supposed that one-inch poultry-netting would keep out rats. We have no mice in Florida. Either they have

Fig. 4 shows the plan of gathering the eggs. The picture shows a little door for each nest. Now, this on some accounts would be very desirable; but it will be quite a saving in time and labor to have one long door that will cover the whole six nests. When this is raised up the eggs will all be gathered very quickly; and I am not sure but I prefer to have the nests a little lower down so we can raise a part of the roof instead of the doors when gathering the eggs. The picture shows the egg-basket standing on the ground. People of my age, I am sure, will object to this, because it necessitates stooping over.

never got there or they do not like the locality. Well, even if we do *not* have mice I found *young* rats getting through the inch-mesh netting; therefore I would have the first two feet of this inner yard made of ¾-inch netting, or, if necessary, of half-inch-mesh wire cloth, and I would have this go down in the ground far enough so that no animals would dig under it. One of our government bulletins recommends bending the netting and carrying it horizontally six inches. Skunks and other animals that dig under, always dig straight down close to the fence. When they find the wire netting runs out horizontally, say six inches below the surface, they will probably give up the job. Under *no circumstances* must rats and other wild animals be permitted to get into the granary; and in order to have things neat and tidy I would never permit a chicken, little or big, to have access to this inner circle. Be sure that nothing gets in during the night time. You will need to have a gate to shut up the roadway nights, say one running up at least two feet.

NOW A WORD ABOUT SITTING HENS.

I have already mentioned one of Stoddard's articles that I said was worth ten dollars to me. It was because of the idea it contained as follows:

I mentioned having four yards out of the sixteen unoccupied the greater part of the year. Suppose in going around you find a sitting hen. Just pick her up and put her

in one of the unoccupied yards. These yards are furnished with food, drink, grit, shells, etc., like all the others. Each yard is exactly like every other yard. If this hen wants to sit on a particular nest in one yard, just give her a setting of eggs in the same nest in a vacant yard. If she does not stay on the nest when you put her there, never mind. She will soon go right back to it, because it is exactly like the nest which she wanted to sit on in the other yard. In this way you can put any number of sitting hens in one vacant yard. Or if there are half a dozen of them, have a second yard for sitting hens. You will notice that the sitting hens with this equipment would have all the liberty of a stolen nest on the average farm. They are outdoors, under natural conditions; and yet they will get back to their nest every time, because it will be to them practically the very nest where they started to sit.

Now, you need not say this arrangement is only a beautiful theory. Friend Stoddard has got it running, and says it works all right. I hardly need remind you that

Fig. 5 shows the feed-hopper that I prefer. It is a large-sized galvanized tub. The wire cloth that separates the yards goes clear down to the bottom of the tub. This tub is placed just midway in the nest-boxes—half of the nests on one yard, and half in the other. The tub should be large enough so the hens can get in and get the feed. No fowls are to be permitted under any circumstances to roost in or about the nest-boxes. You will notice by Fig. 2 that their roosting-houses are a separate affair from the nest-boxes. We want to take every possible pains to have our eggs fresh and clean, without the necessity of washing them; and I think I can manage with the above arrangement so no droppings will be found in or about the nest. After several winters' experience, I notice that my hens seldom or never void their droppings while they are in the tub of feed. They seem to have at least a little sense of the "fitness" of things when they have a fair chance.

the greatest obstacle in the way of conducting a successful poultry-farm, or any other kind of farm for that matter, is the expense of competent help. This up-to-date egg-farm I have been describing, when every thing else is fixed just right, should all be easily managed by one person, or, I think, by any average boy or girl who loves chickens. If the wagon draws in the grain and draws away the eggs, and you have a wind-mill or a spring to furnish the running water, there is very little fatiguing work to be done. Of course, the same arrangement will work all right with ducks; and, better still, because the fences to restrain the ducks need be only two feet high; and the Indian Runners would travel half a mile, or more, if need be, to get to running water, and they will come back every night where they are fed to be shut up until they have laid their eggs.

If chickens are wanted after dark, for the market, or for any purpose, their roosting-places are all together. In fact, your 600 hens can all be under *one* roof, if need be. Do you suggest that this would be a bad arrangement if contagious diseases get among the flock? Yes, it might be a little bad; but with very little effort you can arrange to have them roost, and perhaps lay their eggs also, at a little distance from any other flock; but with proper precaution, such as I have outlined, I believe there is little or no need of having either vermin or contagious diseases. A successful egg-farm, if I am correct, does *not* have any thing of the sort.

One more thing. Every little while we hear of a poultry establishment getting afire and burning up a lot of chickens. I visited a place ten days ago where a brooder-house caught fire, resulting in the loss of something like a thousand chickens. Now, if you are either in Texas or Florida, you can have your shelter and every thing else made of galvanized iron so there will be *nothing* to burn, and no harbor for insects. If you are going to use incubators I would have them in a cement cellar under the granary; and I think I would have this granary also made of galvanized iron so there will be nothing to catch afire and burn up. We have cornercubs here in the North—in fact, we have one on our place here in Medina—made entirely of galvanized iron that keeps both seed corn and buckwheat beautifully. It is all made of cement and perforated iron. There is not a thing about it of wood. If you have electric lights in your vicinity I would have the whole establishment lighted by electricity.

Finally, dear friends, I am just now anx-

ious to get back to my Bradentown home in the fall so that I can remodel my five acres down there, in the way I have outlined above, for my Runner ducks and Leghorn-Buttercup laying hens. I have submitted the whole plan to you thus early in the season so that you may be thinking it over. What is the use of wearing out your *shoes*

and yourself likewise, in traveling miles in caring for your chickens, when the laying hens will gladly do the traveling for you? The hens are "young and spry"—especially the ones that lay the eggs. If they are *not* young and spry it is because *you* are at fault. Shall we not let them do the laborious running?

HIGH-PRESSURE GARDENING

ANOTHER GREAT BIG "DISCOVERY:" THE USE OF LIME FOR GETTING A STAND OF SWEET CLOVER.

The convergent poultry-yard, described elsewhere in this issue, I hope is destined to produce a "revolution" in egg-farms—at least friend Stoddard and I think it may. But we are old men, and both of us somewhat given to riding hobbies. But you just wait and see. Well, now, here is another thing that seems likely to "revolutionize" the great science of agriculture. It is not my invention, however, for it comes from our Ohio Experiment Station. Some years ago Dr. C. C. Miller said if anybody could tell him how to get a solid growth of sweet clover in the fields, like that growing by the roadside, he would be glad to know it. That might have been twenty years ago. Well, our Ohio Experiment Station has been working for about twenty years, and has only in this present year of 1912 gotten at the truth. For their experiments, something like twenty years ago they purchased a farm in Northern Ohio—the poorest worn-out farm to be found, perhaps, in all of Ohio. Last Saturday, June 15, they had a field meeting in order to demonstrate what *lime* will do on poor clay soil, and later I paid a visit to the Station ground at Wooster. Not only sweet clover but alsike, alfalfa, timothy, and red clovers were tested in strips, and all these strips ran across a field where one half was heavily limed, and the other half had no lime. A great variety of commercial fertilizers were also tested across the limed and unlimed land. The result was not only wonderful, but really *astounding*. We saw beds of sweet clover, both white and yellow, as high as one's head, the latter in full bloom; but when this strip ran on to the unlimed portion of the field the result was almost nothing but plantains, wild grasses, and weeds. The results were practically the same at the sub-station mentioned, as in Wooster. The heavy applications of fertilizer amounted to little or nothing without the lime. When we came to a strip, however, where 15 loads of barn manure to the acre were applied, there was a par-

tial stand of the clovers and timothy. The barnyard manure was almost the only thing that compensated for the lack of lime. Some of you know the A. I. Root Co. have been selling sweet-clover seed for twenty years or more; and when the seed that grew nicely here around my Medina home did not do any thing to amount to much elsewhere we have a good many times paid the money back or furnished more seed at a reduced price. Now the truth has just come up. Where the seed was sown on limestone soil it produced a crop. Where fields have been farmed until the lime was used up, sweet clover balked. Once more, wherever stone roads have been constructed through Ohio, and almost everywhere else, especially if said roads were made of *crushed limestone*, sweet clover came up rank, thrifty, and luxuriant along both sides of the road. I think you will find it everywhere if you have your eyes open. Well, this crushed limestone mixed with soil by the agency of the iron wagon-tires, produces just the combination that the clover wants. And these same wagon-wheels distribute the seed for miles along the edges of the road. Another thing, soil thrown up by ditches along the railway, or thrown out by the railway companies, contains more or less lime that has not been used up by exhaustive farming, and therefore the sweet clover grows.

A am sorry to note that the sweet-clover bulletin from the Department of Agriculture, that I have recently quoted from at considerable length, contains scarcely any mention of the fact that sweet clover must have lime. It can not endure acid or sour soils. Within 24 hours after I witnessed these wonderful results I had five kinds of sweet clover planted, each kind running across a bed in the greenhouse, half limed and half unlimed.

In regard to the quantity of lime needed, one of the tests at the Wooster station contained six tons of ground limestone to the acre. Another had 15 tons. There was not very much difference in the results. My impression is that a single ton will furnish all that is needed. See Special Notices.

Editorial

FOUL-BROOD INSPECTION FOR IOWA.

MR. FRANK C. PELLETT, Atlantic, Ia., is now State Inspector of Apiaries for that State. Mr. Pellett will be glad to receive correspondence from those who can advise him with reference to bee diseases in his State.

CLEANING SECOND-HAND SQUARE CANS.

IN our Heads of Grain department, page 553 of this issue, will be found an item from Major Shallard, of Australia, on how to clean second-hand kerosene-cans so that they may be used for honey. The method described by Mr. Shallard, it would seem, would do the work most thoroughly; and if the cans are not damaged nor rusted they would be practically as good as new.

THE FOUL-BROOD INSPECTOR FOR TENNESSEE.

ANNOUNCEMENT has come to us that Dr. J. S. Ward has been appointed State Inspector of Apiaries in Tennessee, with headquarters at Nashville, to fill the vacancy made by the resignation of J. M. Buchanan, of Franklin. Dr. Ward asks the co-operation of the beekeepers of Tennessee in protecting the honey industry, and especially solicits correspondence as to where disease may be found.

BEEKEEPING IN COLORADO.

The reader's attention is directed to a very interesting article in this issue by Dr. E. F. Phillips, of the Bureau of Entomology, Washington, D. C., on beekeeping in Colorado. Eastern beekeepers will be particularly interested, because the methods they use have to be modified to fit the peculiar conditions that exist in those irrigated and elevated regions. An altitude of a mile, and no rains to speak of, and a sole dependence on melted snow from the mountains to water plant life, make it necessary for the beekeeper as well as the rancher to work on a slightly different plan from that used in other territory.

BUSY DAYS FOR THE EDITORIAL FORCE; CARNIOLANS.

THESE have been busy days for the editorial force. The unexpected rush of honey, and swarming, have made it necessary for us to go out into the field and help out the boys. For example, we have had some experience in shinning up trees forty or fifty feet high after swarms—an experience that will not be repeated next year if we know ourselves. Say! those Carniolans, when they get on the swarming rampage, violate all rules—abscond without queens, come out at any time of day, stay in the air for hours, and swarm when queens are caged in the hive. They are excellent bees to breed up, and for extracted honey, but no good for comb honey. Fortunately for us, we have only one yard of them.

MOVING BEES WITHOUT SCREENING; AUTO- MOBILE WAGONS.

WE would call special attention to the article by Geo. J. Van de Vord in this issue on the subject of moving colonies of bees without screening them in the hives. This saves a lot of preliminary work, and effectually eliminates the danger of smothering bees in transit. If an auto wagon is used, there can be no bad spills from stings as sometimes occurs when horses are used.

Auto wagons are now becoming so cheap that the modern beekeeper of fair mechanical skill with out-apiaries can not afford to be without one. The out-apiary scheme requires quick means of reaching yards with loads of empty and filled supers, and the same wagon can be used for carrying the whole extracting-outfit and a force of men to take care of the honey, extract it, and carry it back home to a place of safe storage, away from robbers of the bee kind and robbers of mankind.

J. E. HAND ON THE SICK LIST.

MR. J. E. HAND, producer of fancy comb honey, and successful user of the shallow divisible-brood-chamber hive, inventor of

the Hand switch-lever bottom board for controlling swarming, author of "Beekeeping by Twentieth-century Methods" (published by the A. I. Root Co., 50 cents), a chicken fancier, as well as a honey-producer, has had a relapse of his old nervous trouble, and it is feared he will never recover sufficiently to be able to take up his business again.

For two or three years back he has been quite extensively engaged in the rearing of queen-bees of a high class; and our readers will remember his discovery of feeding bees a thin sugar syrup, made of nine parts of water and one of sugar, in outdoor feeders in such away as to eliminate all robbing during a dearth of honey, and yet keep queen-rearing going on at full headway. Mr. Hand is an original genius—keen, alert; and his many friends will be sorry to know of the infliction that has been visited on him. He is now in the hospital for treatment where it is hoped that he may be restored to his former health.

Mrs. Hand writes that all money sent for queens that her husband could not send has been returned. There will be no use, of course, in sending in any more orders; and if there is any of his correspondence that has been neglected by Mr. Hand, we feel sure that Mrs. Hand will be able to take the matter up. Address her at Birmingham, Erie Co., Ohio.

HONEY-CROP REPORTS UP TO JULY 9.

WE are having a remarkable flow of clover honey in Northern Ohio; and if the season were as good all over the United States as we are having here, and there were enough bees to gather it, the honey market would be glutted in short order. We have had practically four weeks of clover; and it looks now, July 9, as if we might have two more weeks of it. Bees are booming at all our outyards; and swarming—it took us so completely by surprise that we were unprepared for it. The region around Zanesville, O., is likewise reporting a remarkable yield from clover.

Apparently the yield of clover honey has not been as good elsewhere in the United States; but from reports that are now in, there will be far more clover honey produced this year than for some time past. Clover seems to be yielding best in the central and eastern States—more particularly the central. Indiana and Illinois, however, have so far not made much of a showing. Some parts of Canada will have a large yield, and other parts only a fair one.

There have been several good reports from the East, particularly around New York, Philadelphia, and Washington. Excellent

yields have been reported in Maryland, some parts of West Virginia, Kentucky, and Alabama; Missouri poor and Kansas good. Reports from the New England States are scattering. So far no large yield has been reported. There will be some clover honey in Michigan, Minnesota, and Wisconsin, with a little basswood.

Colorado will have a fair yield, probably.

Reports are unfavorable from California. Some orange has been produced, but there appears to be but very little sage. Winter losses have been reported in some of the other western irrigation States; and while alfalfa will furnish nectar as usual, there will be fewer bees to gather it.

Prospects in Pecos Valley, New Mexico, are poor.

In Texas the season has been poor, and the same is true of Florida. Some of the other southern States report a very good yield.

Taking it all in all, it is our opinion that there will be a better crop of Northern white-clover honey harvested than usual; a fair crop of alfalfa, and a light crop of sage. Prices in the East, on account of clover, may be a little easier than last year; but for the present they should hold about the same, for the reason that no accurate estimate of the crop can be given as yet.

In the meantime, we request our subscribers and others to continue sending in reports of what the season has been. Make the reports short—not more than two or three sentences.

DENATURED ALCOHOL FOR REMOVING PROPOLIS FROM SECTIONS; ELIMINATING GLASS FROM SHIPPING CASES.

S. N. HATHAWAY, page 454 of this issue, recommends removing propolis with denatured alcohol, which is now comparatively cheap. We see no reason why the scheme should not work.

We wish to call particular attention to what our correspondent has to say on the subject of using no glass in shipping cases. While we endorse what he says in a footnote, we feel that the matter is so important that we desire to give it further reinforcement here.

The use of glass very materially weakens a shipping case. The wider the glass, the frailer the case. A weak or wobbly case breaks a good many sections.

The front row of sections as seen through the glass very often, and we may say generally, does not tell the truth as to the kind of combs behind them. It is not necessary any more to have glass in the front of the

case to indicate the fragile character of the goods it covers. The old theory was that it would warn the freight and express handlers to be careful; but experience for many years back shows that such warning seldom is of any avail. In fact, the railroad companies are now discriminating against glass in shipping cases. All comb honey nowadays is or should be shipped in carriers. When so packed, the glass will seldom show, even if used. Reliance must rather be placed on large printed labels on the carriers to indicate the character of the goods; and the safety of the comb honey lies really in the fact that the carrier is too heavy to be dumped or thrown. The straw cushion used in carriers will take care of what little jars the sections may receive.

The only argument that can be advanced for glass in shipping cases is for retail display purposes; but as we have argued time and time again, sections can be shown off to better advantage in a regular showcase than between two bars of wood of a soiled, unpainted wooden container.

We believe the time is not far distant when producers of comb honey, and buyers alike, will demand the elimination of glass entirely, not only as an unnecessary expense but as a positive detriment. If the new grading rules adopted by the Colorado Honey-producers' Association, as given in our last issue, should be generally adopted, and if buyers would refuse to take comb honey, except in carriers, in less than ear lots, and discriminate against cases with glass, the comb-honey business would soon be restored to its former standing. Dealers furnish cases made for glass for no other reason than that old usage sanctions them. It is high time that we pack our comb honey in the strongest cases we can make, weight and price considered. Certainly we ought to make such containers as strong as those for bottled goods that are far less fragile.

MANAGER RAUCHFUSS' STATEMENT CONCERNING THE NEW COLORADO GRADING RULES.

We sent Mr. Frank Rauchfuss, Manager of the Colorado Honey-producers' Association, an advance copy of our editorial on Colorado's new comb-honey grading rules. Mr. R., we understand, had much to do with the framing of the new rules. His comments on our editorial will, therefore, be read with interest.

Mr. Ernest R. Root:—Your letter of the 1st inst. is at hand, also advance copy of the article in GLEANINGS relating to grading. I am well pleased with it, and hope your suggestion of having a meeting of honey-shippers and carload handlers of honey, at Chicago or some other place, some time in the near future, will be carried out.

In your editorial you say, "Another very impor-

tant suggestion is that for scraping the section." It should be incorporated in the rules, for it is very important. In prefacing the whole article you say, "Not only the rules but the general suggestions are worthy of careful reading." We should like to call your attention to the fact that we are not making suggestions as to how honey should be graded and packed, but give instructions, and these must be carried out if the honey is to be accepted. There is one slight omission in the description of the marking of "Choice" honey. It should read, "Choice must be marked — (dash) in hand-holes," and directions for extracted-honey producers should read, "Adopt the plan of marking," instead of *marketing*, "each extracting."

In adopting these rules we have held to the view that comb honey is an article that sells principally by appearance; therefore the question of color and finish has been given most prominence. For instance, in our fancy white you will note that honey, comb, and cappings must be white; in the No. 1 it says, "honey, white or very light amber, but comb and cappings from white to slightly off color." While I realize that this term, "slightly off color," is somewhat vague, I have not been able to run across any one who could offer a better description. You know that here in Colorado, especially on the western slope, we have quite a little honey that is of a pinkish order, of very good flavor and body, and very often has cappings that are nice and white except for a little discoloration at the bottom. We realize that such honey as that should go into No. 1 grade, especially if the qualifications of weight are carefully observed as they should be. Now, in the choice grade we have the following description as to color: "white to amber, but not dark." This is another rather vague way of explaining things, but is the best we could do; and when it comes to explaining these matters, the best way to do is to have grading demonstrations. We have had several of them at our annual meetings, and they have been well received by the members. In the grading instructions you will find one clause where it says, "The front sections of honey in a case must be alike in color and finish, and be a true representation of the contents." Now, this disposes of the whole matter where more than one shade of color are permitted in the same grade; because if this instruction is carried out, honey of one shade and finish will be found only in the same case; and the dealer buying the honey can govern himself accordingly. As you well know, in every city there are people who prefer dark-capped honey before the white-capped, although they are in the minority; and by this kind of grading they can easily be accommodated. You will note that no provision has been made for honey where more than fifty cells are uncapped. This has met with some criticism by our people on the western slope. They contend that sections weighing probably 14 ounces, but capped over three-fourths on one side and one-fourth on the other, are good salable sections. However, my experience in the comb-honey business has been otherwise. While there are isolated cases where such honey is wanted, they are not sufficiently numerous to give them any consideration in grading rules. Such honey can usually be disposed of to fair advantage in the home market; or if this is not the case they could be extracted.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION,
FRANK RAUCHFUSS, Manager.
Denver, Colo., July 3.

We are glad to know that the matter is not so much optional as mandatory. Good!

GLEANINGS will be glad to assist in any movement looking toward a more general adoption of these excellent grading rules. We have already written to Secretary Tyrrell, of the National Beekeepers' Association, asking him if it would be possible for him to arrange for a meeting of producers and buyers at some central point, say Chicago, with the view of adopting the Colorado rules as they stand, or making such modifications as might seem wise on the part of all those concerned.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

IT IS FOUND that invertin, which causes the inversion of sugar, is present not only in the saliva of bees, but also in pollen.—*Schweiz. Bztg.*, 512.

WESLEY FOSTER, you ask, p. 330, what a beekeeper would gain over express charges by a parcels post limited to 11 pounds at 12 cents a pound. On a 1-lb. package he would gain 13 to 18 cents, according to distance; on a 2-lb. package he would gain 6 to 11 cents.

C. CALVERT, you seem to think, p. 349, that our eight-frame hives are too small, and that a hive with ten Standard frames is the most useful type. But the frames in our eight-frame hives are $17\frac{5}{8} \times 9\frac{1}{8}$, and your Standard frames are $14 \times 8\frac{1}{2}$; so our eight-frame hives really contain $96\frac{5}{8}$ square inches more frame surface than your ten-frame hives!

YOU ASK, Mr. Editor, what's the matter with manilla hive-tags? Curl up. Glad to have you say they work well at Medina. Perhaps I didn't fasten them on right. Have just ordered another set to try again. How do you fasten them on the hive? [Your unsatisfactory experience with the first set of manilla tags was doubtless due to the fact that we first soaked the tags in linseed oil after they were printed. Like yourself, we found them unsatisfactory. Finally an enterprising Yankee suggested that we soak them in boiling-hot paraffine. Tags so treated stand the weather very much better. But even these will discolor in time; but we have some that have been in use for five years, and we venture to say they will show the numbers fully as well as any metal tags with the figures painted in black. They are so cheap that they can be replaced for less money than it will take to fix up metal tags.—Ed.]

THIS YEAR has been very unusual. Last winter was the killingest winter I ever knew. A good many trees and bushes were killed root and branch (nearly all my roses gone), and much of the grass and clover killed. Loss in some apiaries 75 per cent; in others, 100 per cent. Fed up to June 22. Then a lightning change; clover-bloom seemed to jump out of the ground (increasing ever since), and supers were put on June 24. Within 24 hours honey was in many supers. The flow began too late for a crop, but—I don't know. [We have had four weeks of honey flow, and white clover

seems to be at its height. To-day, July 5, the basswoods are just opening up. If every locality had a flow like the one we are having here, it would be the greatest honey year on record. We never had so much swarming in all our experience, nor so much honey from colonies so weak that they would be supposed to be doing well if they even filled their combs. As it is, they are filling the combs twice over, and the queens would be honey-bound unless we extracted.—Ed.]

● DESIRING data as to distance required for the isolation of a mating station, Frank-Kleist marked 70 or 80 field bees with red or yellow color early in the season when forage was scarce. In the next fortnight he made frequent visits to a field of *Erica carnea* $2\frac{1}{2}$ miles away, and always found his marked bees there. He repeated the experiment when pasturage became plentiful, and never found them further than a mile away. A third experiment, after pasturage was scarce, showed his marked bees again $2\frac{1}{2}$ miles away. But at this same time a spot of good pasturage at a much shorter distance was left unvisited by the bees, because to reach it they must pass over a wooded hill.—*Leipzig. Bztg.*, 66. This looks as if bees do not from preference forage more than a mile from home. [This conforms exactly to our own experience. We have demonstrated over and over again at our outyards that when bees can get plenty of nectar within a mile or a mile and a half, they will not go further; and why should they? Usually a clover flow will give bees all they can do within a radius of a mile and a half; and basswoods will take care of twice the number of colonies within the same radius. Or, to put it another way, the same number of bees would not require more than half the radius needed by clover. But when forage close at hand is scarce, bees will go two and a half and even three miles, providing the flight is over a level plain without obstruction. A piece of wooded land will often prevent bees from going even a quarter of mile to a fine field of alsike—that is, assuming that the woods are between the bees and the field. When we furnish alsike at half price to beekeepers within a mile of our apiaries we make sure that the field to be sown is not the other side of a piece of woods nor high hills. Taking it all in all, our experience exactly coincides with that of Mr. Frank-Kleist.—Ed.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

Mr. Holtermann's suggestions on page 228, April 15, as to using wires in brood foundation is to the point when he says the wire should be placed where there is the most sag in the combs at the top. It is rare indeed that we find cells out of shape for more than two inches below the top-bar, whether there are wires below this point or not.

* * *

Some very wise person has remarked that you can't tell by the looks of a toad how far it will jump, and it is true. The same might be said of many inventions relating to bee-keeping. You can't tell by the looks of them how far they will jump nor whether they will prove to be of permanent value. There is Hand's bottom-board that I saw in actual use at Prof. E. L. Baldwin's, at Deland, Fla. Prof. Baldwin was much pleased with it, and it seemed as though it might prove to be a success. Certainly the bees of that hive were working with an energy unsurpassed by any other colony in the yard.

* * *

Railroads get their share of abuse for their heavy freight rates and methods of business; but have we stopped to realize their immense value in transporting products that otherwise would be of little value, and conferring a benefit on both the producer and consumer? I am reminded of this as I see the enormous amounts of fruits and vegetables shipped from the South during the winter months to the cold North that otherwise would have to go without them. Picking up a can of cream with which to flavor my coffee at the dinner-table to-day in southern Florida, I noticed it was put up in the opposite corner of the country, Seattle, in the State of Washington, four thousand miles away; and yet it was as sweet and delicate in flavor as if it had come from a creamery this very morning. Great as are the problems and abuses of transportation, the blessings are even greater.

* * *

On page 190, April 1, Wesley Foster makes out a strong case against our postal laws and a pretty bad one against our express companies. I believe, however, some allowance should be made for the size of the United States when we consider the immense distances packages have to be carried in this country as compared with

the distance covered by most of the nations of Europe. For instance, the area of the United States, not including outlying portions, is not far from nineteen times that of Germany or France, while the rate on parcels is only twelve times as great. Switzerland, with its one cent a pound, is only about one third the size of the State of New York. So far as the express companies are concerned it looks as though they were willing to take all they can get; and their avaricious nature should be curbed by some vigorous legislation that would compel them to do to others as they would like to be treated themselves—38-per-cent dividends!

* * *

PUTTING THE BEES THAT SWARM BACK WITH THE PARENT COLONY.

Mr. Doolittle, p. 227, Apr. 15, tells how to increase and secure a crop of honey, and, incidentally, how *not* to increase too much when relying on natural swarming. In caring for a yard of bees for Mr. O. O. Poppleton during a large part of last March, not wanting much increase, I hived the new swarm in a hive, and left it for a few days until it had gotten over its swarming fever, and then dumped the bees back into their own hives, or some other that had recently swarmed. This seemed to work very satisfactorily. Scarcely a colony so treated swarmed again.

* * *

THE EFFECT OF TOO MUCH COLD WIND.

Page 191, April 1, J. L. Byer gives some interesting notes on the wintering of bees and the effect of shade and wind. In looking over a yard recently for foul brood the proprietor said his bees had wintered very badly. Coming to one side of his yard, "These," said he, "are almost all dead," and I found them so, as not one in five was alive. In another part of the yard he said, "Now, these are pretty fair," and, sure enough, they were almost all alive. What made the difference when the season last year was the same for all? Just this: Those that were pretty fair were to the south and leeward side of his honey-house, while those that were nearly all dead were at one side where the wind swept around the house and blew even harder than in the open fields; for if we block a current of air or water it will move faster around the obstruction than where there is none. I like a little circulation of air, for it keeps the temperature more even—but not too much.

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

THE HONEY-CROP REPORTS.

The old saying, "There's many a slip 'twixt cup and lip," has once more shown itself only too true when applied to this year's honey season in the Lone Star State. A little over two months ago I reported most favorably on prospects for a bountiful honey harvest. Since then the tide has changed, and the change is so pronounced that it means that Texas will have the shortest crop that we have ever experienced. Nine weeks ago there was every indication of a bountiful honey crop. Vegetation and all kinds of nectar-yielding blossoms were most plentiful. The bees were in excellent condition, and beekeepers everywhere were jubilant over the fine prospects. As it is now, southwest Texas, where the bulk of the honey of this State is produced, has not had a crop. The main flows in the spring, guajilla and catsclaw, and also the mesquite, did not come out as usual; and the horsemint, while abundant in most localities, did not yield nectar. This is attributed largely to the unusual season—the long-drawn-out winter, followed by a late spring, and too cool nights that prevailed long after spring finally opened. Although there was a profusion of bloom, nectar was very scarce, even when the bees were not hindered by unfavorable weather from going to the fields.

In a nutshell, the weather conditions were not favorable to the proper development of the blossoming of the honey-yielding plants, and the atmospheric conditions were not conducive to the secretion of nectar in those blossoms that did exist. There is still some hope of the mesquite yielding a summer flow, especially in those regions where recent rains have been plentiful. Whether this will materialize is hard to tell as yet. The State, outside of southwest Texas, is entirely different. Here the honey crops come somewhat later, as a rule. Sometimes early crops in April are obtained also, where mesquite prevails.

In eastern Texas basswood abounds in several localities, and this year it yielded an abundance of honey in May.

All beekeepers who are located in the cotton belt of central Texas and further north are figuring on a good yield from cotton. Recent heavy rains have made these prospects most excellent. The bees have just begun on the cotton; and as it is coming into bloom rapidly, a harvest from this source ought to be assured. The cotton honey-flows are long and slow, and usually

last until frost if weather conditions are favorable. With too dry weather in the fall the cotton plants usually cease to blossom, and also shed their foliage, so there is no nectar to be had, and the flow is cut short.

* * *

BULK-COMB-HONEY PRODUCTION.

On several occasions I have avoided writing on the above subject mainly because I do not like to harp on one theme continually. The inquiries have become so frequent that it seems as though the subject might be of general as well as individual interest. What is said about bulk-comb-honey production in this department is partly in reply to letters which can not be answered promptly at this season of the year, and partly because there is a somewhat extended desire for information on bulk-comb-honey production, as indicated by the numerous letters from so many different States. That bulk comb honey has found favor among beekeepers in other States than in the South is indicated by numerous communications to this effect. It is indeed gratifying to note this, since I have always believed and have contended that its more extended production would mean a better distribution and a better price for honey.

There is as yet a very wide opinion as to the best way of producing this honey, and a still greater difference as to the way of marketing it and putting it up to the best advantage, and most economically for the trade. It seems as though every producer has a different way of marketing this product. The sooner a uniform method of packing and marketing can be established, the better. Since the pure-food laws came into effect, the question of the proper weight of the various Texas standard packages has arisen, and a movement to regulate this is on foot now. As soon as this is settled, it will mean that all bulk comb honey in Texas will be put up one way, and will be known to producer and buyer alike.

The question that arises is whether the standard packages used in Texas would be the suitable ones for other parts of the country. I see no reason why they should not be, especially since they are already of standard manufacture. It is only necessary to try these out to ascertain their adaptability; and for the information of those who desire it, a full description of the various kinds and sizes we use will be given in a subsequent issue of this journal.

BEEKEEPING IN CALIFORNIA

P. C. CHADWICK, Redlands, Cal.

I wonder what California would do with her honey if all conditions should be just right once. The crop would be enormous.

* * *

From letters received I am led to the conclusion that San Bernardino County is not the only place where the foul-brood inspector is not giving satisfaction.

* * *

My youngest son has discovered that bare legs in the apiary are preferable to legs covered with black stockings so far as the number of stings received is concerned.

* * *

"It is an ill wind that blows no good." For weeks we fretted and fumed because of the dark cool weather holding the bees back; but many failed to realize that other things were being held back at the same time. At this date, June 1, there is still some orange bloom, this being the latest date my knowledge records for this bloom.

* * *

The well-known phrase, "Keep more bees," is all right in a way, but it is necessary to have the way as well as the means. No one would like to increase his holdings more than the writer, and I am trying to accomplish it as fast as possible; but so long as family expenses are more certain than honey crops, and with six children to feed, clothe, and educate, I must go carefully and look first to the welfare of a growing family, branching out as the way opens.

* * *

There is a fast-growing sentiment against grading honey water-white. There is a very small amount produced that is actually water-white, and what there is should command a fancy price over the next-best grade. Buyers are largely responsible for the dissatisfaction in this grade. Contracts are taken early in the season for water-white. If the season is poor and the supply limited, any fair grade is usually taken under the contract; but if the season is good and the supply large, much quibbling is done over color, and only the very best lots are accepted without question.

* * *

Mr. E. D. Bullock, of this city, has secured 8 tons of orange honey from 240 colonies moved in from the sage-fields. This is the largest amount per colony secured by any one, so far as I have learned. In a recent conversation with Mr. Bullock he told me of having fixed a watering-place

for his bees, which was used freely until the orange bloomed, after which it was deserted—the conclusion being that they secured an ample supply of water from the thin nectar of the orange.

* * *

Some orange honey has been secured. The weather has been very favorable since May 12, sage yielding well, but the bloom being very limited, and no prospect for a large amount being stored. The sage weevil has been the worst for years, many buttons being entirely destroyed before blooming. A slow flow for some weeks is probable from alfalfa (wild) and white sage; the button variety will soon be finished. Late buckwheat should yield well this season. Many who are located out of reach of early pollen and nectar yielding plants, owing to the extremely dry winter, will secure only a very limited crop.

* * *

HOW TO REACH THOSE WHO DON'T TAKE BEE JOURNALS.

I have been criticised for saying so much about foul-brood conditions in our State. I believe I have written nothing but the truth regarding this matter. The chief objection seemed to be that, in giving these facts to be published, I have been scattering it all over the world, when it concerns only us in California. If I am reaching the beekeepers of the world by trying to wake up our California readers to the extent of their danger, all well and good; but how to wake up a few thousand that take no bee paper is a puzzle to me. Considering the number engaged to a greater or less extent in the industry I believe California can show up a greater per cent of ignorance than any other State in the Union. This is not saying, however, that we do not have some of the foremost producers in the world.

There is a general sentiment in favor of a new and better foul-brood law, but some jealousy exists between different factions and individuals. This should not be carried to a point that will jeopardize the enactment of a new law. Every association, club, and individual should help secure this much-needed legislation. This campaign will be my last effort to help secure a new law. It is not a selfish effort on my part, for, from a selfish standpoint, I would rather let the disease spread and clean about two-thirds of the bees from the ranges. I can take care of myself.

Conversations with Doolittle

At Borodino, New York

MANAGEMENT OF SUPERS.

"Some of my colonies are working nicely in the supers of sections; others are not at work at all. How can I manage the colonies in general so as to secure the best results?"

"The first thing is to be certain that the colonies are all strong enough for work in the sections. Many put on supers promiscuously, without regard to strength of colony, and then wonder why all do not go to work in the sections. It is of little use to put supers on any of the hives until the brood-chamber is well filled with brood and bees, as a good yield can come only from colonies *strong* in bees.

"But sometimes it pays to start colonies at work above a brood-chamber which is being filled with bees from the brood after the combs are about three-fourths filled. This is done by putting a queen-excluder over the brood-chamber, and putting a super of half-depth extracting-combs on top. This half-depth super full of combs gives the bees a chance to store any small amount of nectar that may be coming in, or to remove any honey from the combs below that may be in the way of the laying queen. At the same time, the bees become accustomed to working above their brood. Now, when the flow of surplus nectar comes, if this extracting-super is removed and a super of sections having one or more baits is put on, the bees, being used to going above, will occupy the sections at once, and work will progress in the right direction.

"If the colony is very strong, this first super can be raised after three days, and a super of sections filled with foundation placed under the first one. The bees will then begin to draw out the foundation, thus relieving any congestion of bees in the hive. This is a great help toward overcoming any disposition to swarm, as well as toward the filling of a larger number of sections. Now, if it should happen that some colony is not at work in the sections, the upper super of some strong colony, in which good work is being done in both supers, can be removed in the middle of the day and carried to the colony in question, putting this super next to the brood-chamber, and the super in which no work is being done, on top. In the middle of the day, nearly all the bees in any super are young bees, therefore are received with their stores at once as part of the family, so that the work goes on without interrup-

tion. The colony from which this super was taken will probably need another.

"If the season for surplus is not far advanced, another super can be put under that already on; but if there is any doubt as to where to place it, I consider it better to put it on top. Putting a super underneath sometimes results in many sections in which the work has not been completed, if any thing happens to cut the season short. In case of a 'downpour' of nectar or a long-drawn-out season, putting the extra super on top gives ample room for expansion, and most of the sections worked in will be completed.

"After having been caught two or three times by a shortened season, with thousands of unfinished sections and only hundreds in marketable shape, because of putting the empty supers under, I have adopted the plan of putting the empty super on top at all times except during the fore part of any bloom which is likely to give a surplus in the sections. By this shifting of supers, bees and all, from hive to hive as needed, all colonies are in a measure equalized, as the young bees when taken with the supers usually stay where they are carried. I do not think it a good plan to put an empty super (that is, one having the sections filled with foundation) under a super in which the bees are at work until the one already on is at least half or two-thirds filled, for the bees to quite an extent will begin to draw out the foundation, storing honey therein, so as not to have a vacant space between the 'treasure house' above and the brood below. It generally results in unsealed, thin, lean, or 'washboardy' sections, which are not wanted.

"As the season draws toward a close, the work should be in an opposite direction from that at the start, as it is well to have all half-filled sections finished as rapidly as possible. Where colonies are slowing up in their supers, such supers should be taken, bees and all, and set on the super of hives from which a super of finished sections has just been taken. This, you will note, is the reverse of the plan used at the beginning of the season, for we now give to the strongest and take from those slowing down. The bees from this shifted super, now set on top, are doing more than they would where they came from by reinforcing those that were doing good work before, while the colony from which they were taken is not impoverished thereby."

THE PURPLE AND BLUE FLOWERS OF NORTH AMERICA

Do Bees Show Preference for any Color? Are they Color Blind?

BY JOHN H. LOVELL.

There are 422 purple flowers in our eastern flora. Purple is an artificial rather than a natural category, and the term is used rather as a matter of convenience. It is widely used by systematic botanists, and, though open to many objections, there seems to be no convenient substitute available. If an accurate scale of colors should ever be adopted it will very likely be discarded altogether. All colors with their various tints and shades, including the browns and grays, are represented in the solar spectrum except purple. This sensation is produced by the combination of two sets of light-waves—red and blue, or violet. Often purple flowers contain two or even three pigments. It has been suggested that, instead of attempting to name their hues, the percentages of the different colors composing them should be given. By using Maxwell's color-wheel the purple of the dahlia may be produced by mixing 14 per cent red, 7 per cent blue, and 79 per cent black. Heliotrope purple is produced by mixing 25 per cent each of red, blue, black, and white. While such formulæ have the value of accuracy, it may well be doubted whether they would convey to the average person much idea of the color of the flower.

Purple flowers may be divided into three groups—dull or lurid purple, red purple, and blue purple. Red purple should usually be classed with red flowers, which as a rule they resemble in structure and manner of pollination, as in the orchis, geranium, loosestrife, and evening-primrose families. On the other hand, blue-purple flowers belong with blue flowers, as in the pea, figwort, and mint families.

Dull or lurid purple flowers are often adapted to flies. The purple trillium, which children so often gather in early spring, only to throw away soon because of its disagreeable odor, contains no nectar, and is attractive to flies alone. In the lurid-purple flowers of the Dutchman's pipe, the calyx is prolonged into a tube, with a contracted throat, either straight or shaped like the letter S, which is set inside with reflexed hairs. Flies can creep in easily, but the hairs prevent their escape. As soon as the anthers have ripened, the hairs wither, and the imprisoned insects, now more or

less covered with pollen, are set free. These flowers should be compared with the pitcher-like leaves of the pitcher-plant and the spathes of Jack-in-the-pulpit, as all three serve as traps for small flies, and are lurid purple, a color which is thought by some to be attractive to these insects.

Brown flowers usually owe their hues to a mixture of chlorophyll or carotin with anthocyan. There are two kinds of pigments in the flowers of the Carolina allspice and the North American papaw, in gooseberries, and various species of orchids. In the European flora, bartsia has black flowers; but I know of no wild flowers in the Eastern States which are black, though a number have black centers; but under cultivation we have black pansies and tulips.

THE BLUE FLOWERS OF NORTH AMERICA.

The blue flowers in northeastern America number 325. Blue is the highest color in the floral world, and undoubtedly blue flowers were the last to be evolved. Blue is Nature's favorite color, the hue which she has reserved to adorn her culminations in flower-building. Simple, small, regular flowers, as has already been shown are usually white or yellow, as the water-plains, buttercups, and five-fingers; but genera and families with highly modified odd-shaped corollas are most frequently blue-purple or blue, and often they are variegated with other hues. For instance, in the buttercup family, while the buttercups are yellow the bilateral larkspurs and aconites have blue sepals and petals. Again, in the rose family the regular rotate five-fingers are yellow and the roses are white or red, but there are no blue blossoms; but in "the sister family" of the *Papilionaceae* or pea family, where the corolla is butterfly-shaped, blue and blue-purple forms are common.

Many violets are also blue, but some species occasionally revert to yellow. In some flowers of *viola tricolor* the petals are yellow when they open, and gradually change to blue, while others change to blue before they open. There are varieties of the pansy with both yellow and blue flowers, and a number of the simpler species of this genus always have yellow flowers. Thus there is good reason for believing that the primitive or ancestral forms of the violet family were yellow. All the twelve species of the spiderwort family, except one which is rose-colored, have blue flowers. They are attractive to bees, as are also many blue flowers in the lily and iris families.

Among the apetalous families, which number 384 species, there are no blue flowers. The flowers are mostly small, and have probably degenerated. In the heath, huckleberry, and primrose families; in the mustard, saxifrage, rose, mallow, St. John's-wort, evening primrose, cornel, and (with three exceptions) the carrot, and many other families, there are no blue flowers.

It is in the gentian, borage, verbena, mint, nightshade, figwort, and bell-flower families that blue flowers reach their maximum. All of these families are of comparatively recent origin, and they contain nearly 400 blue-purple and blue flowers. In the mint and figwort families, flowers of these colors are very numerous, and are often dotted, striped, or maculated with white, yellow, and red. We have here the culmination of color display among flowering plants.

These flowers possess very singular forms, as in the skullcap, monkey-flower, and snapdragon; and the nectar is so deeply and carefully concealed that few insects besides the long-tongued bees can obtain it. In some instances a single species of flower is visited by a single kind of bee, as one of the larkspurs by one of the bumblebees. In general, all blue flowers are bee flowers. But not all bee flowers have bizarre or grotesque forms. The gentian family contains 16 regular flowers, which are blue and likewise adapted to bees. In the Alps the gentians are very abundant, and display vivid masses of blue coloring. Huxley, while seeking health in the bracing air of these mountains, found great pleasure in studying these flowers, to an account of which his last paper was devoted. The intensity of their blue has been well described by Bryant in his lines to a fringed gentian:

Blue, blue, as if the sky let fall
A flower from its cerulean wall.

A generation ago Sir John Lubbock (Lord Avebury) published an account of some experiments he had made, and asserted that they proved that honeybees prefer blue to any other color. This statement was universally accepted and everywhere published. Hermann Muller also made many similar experiments, and came to the conclusion that honeybees prefer blue to red, and red to yellow or white. According to these observers, blue flowers have been developed in response to this preference of bees; but why they prefer this hue they have never attempted to explain. Their selective influence had developed blue-colored blossoms, it was believed, in a great variety of families. On the other hand, a blue flower, other things being equal, is more

likely to attract bees than any other hue. But later naturalists are inclined to be more skeptical. Cowan, in his well-known book on the honeybee, says that Lubbock's experiments are not at all conclusive; and after carefully reading the original descriptions I quite agree with him. Plateau declares that Muller was misled by a too vivid imagination; and that not only do honeybees exhibit no preference for blue, but they can not even distinguish between colors. In this latter assertion Plateau was mistaken, as I am showing in a series of articles in the *American Naturalist*. Bees easily distinguish between different hues; but whether they are more strongly influenced by blue than any other color I do not as yet know. I certainly do not think that it affords them an esthetic pleasure.

If, then, blue coloring has not been developed in response to the esthetic sense of bees, can we account for its appearance in any other way? Let us make the attempt. Simple, wheel-shaped flowers, which have the nectar fully exposed, are usually white or yellow, and are visited by a great variety of insects. The buttercups, water-plains, five-fingers, and many genera in the mustard, saxifrage, and carrot family are familiar examples. Insects often visit indiscriminately these species, which still retain the power of self-fertilization.

On the other hand, genera adapted to bees usually display a variety of colors, as violet, blue, brown, red, yellow, and white, especially when they bloom in the same locality and at the same time. Common examples are the aconites, sages, and clovers. The nectar is more or less deeply concealed, and the floral mechanisms are often intricate.

Honeybees in collecting nectar are faithful, as a rule, to a single species of flower—they exhibit "flower fidelity." Even when the flowers are nearly alike in form and color, the bee often shows a remarkable power of discrimination. If all the flowers blooming at the same time in a locality were of the same color, it is evident that bees could not distinguish between them as readily as when there is a variety of colors contrasting with each other. Numerous color difference in bee-flowers are, therefore, an advantage both to the bees and the flowers; and this is the reason that they have been evolved. There can be no doubt that bees can distinguish between different hues, and can make their visits more quickly and easily because of the contrasts of flowers in coloration. In the development of bee-flowers from primitive genera, red and blue hues have appeared, not because

they gave the bees an esthetic pleasure, but because of their utility.

Both red and blue flowers owe their coloring to a pigment called anthocyan, dissolved in the cell-sap, which in the red flowers is acid, and alkaline in the blue flowers. Anthocyan is probably a compound of a tannic acid and a sugar, for it occurs only in plants containing tannic acid, and it rapidly increases when such plants are fed with an invert sugar. Its formation is also stimulated by strong sunlight. Very likely, instead of one pigment there are several closely related soluble pigments.

If the cell-sap is very strongly acid, a red flower will be likely always to retain its hue; but if it is nearly neutral it may change to blue, either in the bud or after expanding. Finally, if the cell-sap is alkaline the blue hue will appear in the bud. In both fruits and flowers, as they mature, the acidity tends to decrease. This is very noticeable in many fruits, where, from being hard and sour, they become sweet and mellow. In the blueberry and many other berries the color becomes blue.

A majority of bee-flowers, as a matter of fact, are red or blue. Of 100 species of bee-flowers growing in the Alps, 34 are white or yellow, and 66 red or blue. In the German and Swiss flora, 152 bee-flowers are white or yellow, and 330 red, violet, or blue.

Blue flowers often change to white, sometimes to yellow, and occasionally to pink or red. In the *American Garden* for January, 1890, a variety of perennial phlox is described, the flowers of which in the morning were clear blue, remaining this color until nearly noon, when they gradually changed to a delicate pink, and by evening were a beautiful deep rose.

Many purple and blue flowers are valuable as honey-plants, as asters, thistles, borage, blue lupine, blueweed, catnip, and to a variable extent many other species belonging to the pea, mint, and figwort families. Blue flowers, however, appear as a whole to be of much less value as sources of nectar than yellow or white ones. The blue lupine, for instance, in Texas in some seasons completely carpets the ground for miles; but according to Scholl it does not yield nectar very abundantly, and in some years fails entirely.

As the result of our examination we conclude that the secretion of nectar does not depend either upon the color or form of the flower. The catkins of the poplar are pollinated by the wind, and do not contain nectar; but there are nectaries at the base

of the leaf-stalks. Both the flowers and the leaf-bracts of the cotton secrete nectar. Mr. Yancey says in GLEANINGS, "When atmospheric conditions are just right, such large drops of nectar will collect on these leaf-glands that one may readily taste it; and a bee has to visit only a very few to obtain a load. At such times they neglect the blossoms entirely, and the honey comes in with a considerable rush." Many other plants also have extra-floral glands. They occur on the stipules of the common field bean, and likewise on the leaf-stems of some kinds of plums. Nectar-glands are also found on the stalks of some species of ferns so that primarily this function seems to exist quite independently of insects, though of course it has been developed in flowers to attract their visits.

Finally, in the lists of honey-plants the elm and hazelnut are occasionally included. Both are wind-pollinated, and contain no nectar. Neither is the cardinal flower of value to the beekeeper. It is adapted to hummingbirds, and the nectar is beyond the reach of bees.

Lists of honey-plants should distinguish between flowers pollinated by insects and those pollinated by the wind. The latter, according to my experience, do not contain nectar, though there are sometimes extra-floral nectaries. The plantains and a few other species, however, are in an intermediate stage, and are pollinated both by the wind and by insects, and are nectariferous. It would also be of interest to state the color of the flower, the kind of odor, if any, it possesses, also its form, and whether conspicuous or not; whether the nectar is deeply concealed or fully exposed, and whether there are numerous other visitors.

Waldoboro, Me.

THAT IMPERIAL COUNTY ORDINANCE

Bluff Legislation

BY J. EDGAR ROSS.

On page 90, Feb. 1, there appeared a short letter from A. F. Wagner, our county bee inspector, stating that an ordinance had been passed by the board of supervisors that would prevent the shipment of bees into this county after Feb. 1. The letter escaped my notice at the time, though I afterward read the comments made upon it by other writers, and thought there must be a misunderstanding somewhere, as I was quite sure that no such ordinance had ever been passed.

An ordinance *was* passed by the board of supervisors, they no doubt believing that it was for the "protection of the bee industry of this county;" but as it turned out, it looks like a piece of jobbery, and no real attempt has been made to enforce the ordinance beyond trying to bluff any newcomers who were not in the clik. In a measure this bluff has been successful.

The history and a summary of the ordinance in question might be interesting to the readers of GLEANINGS. A copy of the ordinance in force in Orange County was brought before the Imperial Valley Beekeepers' Association by Mr. Wagner, who sought the association's endorsement upon a similar one for Imperial County. It was not enthusiastically received, but Mr. Wagner was appointed a committee of one to secure signers to a petition asking the board of supervisors to pass the ordinance. This did not meet his approval, and he called a meeting of the Valley beekeepers to consider the matter. Of about fifty beekeepers in this valley, just nine responded. I was the only one of the nine who opposed the ordinance, and my opposition was based upon my belief that it could not be enforced. I had no thought at the time that it was to be used as it has been since its passage.

The ordinance, in brief, provided that any bees brought into the county must be marked with the place whence they came, and that the inspector must be notified within 48 hours of their arrival. There were other minor provisions that really added nothing to our State law, and were practically worthless as a safeguard against the introduction of brood diseases.

But here was the joker. It gave the inspector power "to quarantine bees from any county, State, or foreign country, where brood diseases were known or suspected to exist." That practically meant everywhere. But the law gave the inspector no power to enforce his quarantine, nor did it attach any penalty for violating it. I asked Mr. Wagner how he expected to enforce his quarantine, but received no satisfactory answer. I signed the petition, however, as I believed he would make the attempt, and it would give the courts an opportunity to decide whether or not the law would hold.

Since the passage of the ordinance, bees have been brought in by the carload from infected counties by the most enthusiastic supporters of the ordinance, and without any opposition on Mr. Wagner's part.

Mr. Roy Bateman, a farmer located near this place, decided to embark in the bee

business, and went to Mr. Wagner to make arrangements about bringing in a carload of bees. As Mr. Bateman was an "outsider," he was forbidden; but upon his insistence that the ordinance was unconstitutional, Mr. Wagner told him to consult with a certain beeman in this vicinity, saying that if this man made no objections it might be arranged. Though I have as many or more colonies of bees than the man in question, I was not consulted, possibly because Mr. Wagner felt sure that I would tell Mr. Bateman the truth of the situation, and welcome him to the ranks of beekeepers, while he could depend upon the other party working the bluff for all it was worth. Mr. Bateman, however, refused to be bluffed; brought in his carload of bees, and when they were inspected by Mr. Wagner the latter made the remark that that ordinance would frighten away some people anyhow. Shortly afterward I took Mr. W. to task at a meeting of the beekeepers' association for non-enforcement of the ordinance, and he said he was doing all he could, and that it had kept out at least 2000 colonies of bees. That is the key to the entire situation. *It was meant and is being used to keep out bees, not bee diseases*, and it succeeds in this only when the incoming beeman can be bluffed, for Mr. Bateman is not the only "outsider" who has brought in bees.

I do not mean to encourage the importation of bees into this county. There may be, as most of the older beekeepers claim, quite enough here already. I have 600 colonies in a territory less than one mile wide and six miles long, and there are four other small apiaries in this territory, besides many scattered bunches of from three to a dozen colonies, and bees could probably be bought in the county cheaper than they could be shipped in.

But I strongly disapprove of "bluff" legislation of any kind. This quarantine regulation and inspection of bees in general is a good thing; but it has often been abused, to the detriment of the public at large and to the beekeeping industry. The idea of quarantining healthy bees because they came "from a county, State, or foreign country where brood diseases are known, or suspected, to exist," is preposterous. We have foul brood right here in Imperial County, so we can not keep out that disease by keeping out all bees.

Let us have no more of these stupid county ordinances. Our State law is sufficient until we can get a better one.

Brawley, Cal.

FIG. 1.—Irving Kenyon's apiary and honey-house, near Syracuse, N. Y.

SCREEN DOORS FOR HONEY-HOUSES

A Practical Scheme for Making One that can be Opened Either from the Inside or Outside of the Building when both Hands are Occupied

BY IRVING KENYON

[When we visited Irving Kenyon, a beekeeper who lives just outside of Syracuse, N. Y., we were particularly pleased with some very ingenious contrivances that we saw at his place; and one of them was a scheme for opening a screen door without using a hand. The middle crosspiece projects beyond the side of the door, making it possible to open the door with the elbow if the hands are loaded. But the reader's attention is directed particularly to the "kick-open" projection at the bottom; see Figs. 2, 4, and 5. For a little simple thing that any one can make and attach to his honey-house doors, either solid or screen, it is the best labor-saver we have seen in any beeyard for a long time. To use the language of the boy, "It takes the cake."—ED.]

I take pleasure in describing some of the plans and fixtures used in our beeyard work which may be of interest to the readers of GLEANINGS. In making a screen door for our honey-house I had several points in view. First, it must keep the bees from getting in, and also allow any that may be carried in to find an easy exit. Second, it should be made so the wire cloth may be renewed easily. Third, it should be so arranged that it can not mash bees in closing. Our old door mashed any bees that were near the frame when it closed, giving the building an unsightly appearance; then it warped at the top enough to let the bees in. When put together with nails it was not easy to renew the wire cloth. The door shown in the picture obviates all of these troubles, as the description will show; besides, we have it now so we can open the door from either side with the foot if we have hives or supers in our hands.

By looking at Fig. 2 it will be seen that the inside of the frame of the screen door is the same width as the opening for the wooden door of the building, giving us the benefit of all the light and air possible.

Perhaps the reader will be able to understand better if I give the measurements I used; then he can vary it to fit his door. I would advise using soft pine for the door-frame, as it is less liable to swell and warp

FIG. 2.—Kenyon's honey-house screen door, showing how it is opened with the foot.

FIG. 3.—Diagram of Kenyon's screen door; the lower "kick-open" device not shown.

than most other woods. The reader will probably use such thickness of lumber as he thinks is required or is most convenient; but I will assume that it is all $\frac{7}{8}$ inch thick; so in giving measurements I will not mention thickness. I used $\frac{7}{8}$ lumber for all except pieces No. 13, 15, and 16. To help the reader to understand where each piece goes we will number them as per the diagram here shown. Nos. 1 and 2 are the sides, and are $2\frac{3}{4}$ inches by the length required to extend 6 inches above the door, and 4 inches below if the steps will allow it. Nos. 3 and 4 are $2\frac{3}{4}$ in. by 3 ft. $5\frac{1}{2}$ inches. No. 5 is $2\frac{3}{4}$ in. by 3 ft. $11\frac{1}{2}$ inches. This is the center crosspiece.

No. 7 is 6 in. by 3 ft. $5\frac{1}{2}$ inches. This piece should be so placed that its lower edge will be one or two inches above the threshold of the wooden door. See Fig. 2.

No. 6, not shown, is $2\frac{3}{4}$ by 3 ft., and goes between Nos. 1 and 2, directly back of No. 5, and is fastened to No. 5 with screws, the wire cloth being between 5 and 6.

No. 8, not shown, is 6 inches by 3 feet. It goes back of No. 7, and is fastened to it with screws. Nos. 7 and 8 are made wider to help stiffen the door and to push against with the foot to open the door from the inside when the hands are engaged. All of

these joints should be squared in a miter-box if possible.

The manner of putting the door together will be almost apparent from the diagram and the half-tone illustration accompanying. Strips 1 and 2, as well as crosspieces 6 and 8, not shown in the diagram, that go under 5 and 7 respectively, are temporarily tacked to the floor while the wire cloth is being fastened on. In doing this, care should be taken to see that the cloth is properly stretched to avoid any baggy places. Cross-strips 3, 5, 7, and 4 are next screwed in place, as shown by the screw-heads in the diagram, leaving the wire cloth under and between strips 5 and 6 and strips 7 and 8. Screws are used so that the wire cloth can be renewed at any time. The position of 7 and 8 should be just above the floor on the inside to receive the bunt of the foot to open the door when operator is coming out. By consulting the illustrations, Fig. 5 particularly, a sort of projection will be seen, the purpose of which is to enable the operator, when going in with a load, to open the door with one foot. When Mr. Root was here he seemed particularly pleased with the kick-open arrangement, and it is certainly a great convenience and a time-saver when both hands are carrying a load.

FIG. 4.—Another view of the door, showing the bee escape at the top.

FIG. 5.—The "kick-open" device.

For the bee escape over the door we want two pieces, Nos. 11 and 12, $1\frac{3}{4}$ inches wide by 20 inches long. Next, two pieces, No. 13 and 14, about 2 inches wide by 3 feet $7\frac{1}{4}$ inches long. No. 15 is $1\frac{3}{4}$ wide by the length required to reach from the lower left-hand corner to near the center of No. 13. No. 16, of course, is to be the same length for the other side. Nos. 15 and 16

FIG. 6.—The bee escape above the window, on the outside.

are to be about $\frac{3}{8}$ inch apart at the top. It would be better if Nos. 11, 12, 15, and 16 were tapered to $\frac{3}{8}$ inch at the top. The bee escape is put together in the manner shown in the diagram over the door. The wire cloth is cut large enough so that it will project two inches above the top piece No. 13. It is then nailed to the back of pieces 13 and 14, taking care to have it project above 14 by 2 inches. Wire cloth and cross-pieces 13 and 14 are then screwed and nailed to 11, 12, 15, and 16 after they are in place. When properly put up, bees that collect on the inside of the door can crawl upward into the escape and finally out at

FIG. 7.—Uncapping-box with screen tray above, tipped up to show the construction.

the apex made by pieces 15 and 16 at the top.

In taking off our honey we sometimes find the bees in such condition that we can shake most of them out of the supers with a few shakes. Then the supers are taken to the honey-house and placed on end 3 or 4 high, so arranged that the light from the door will shine through them. The windows being darkened, the bees collect on the door, which we open occasionally, and jar them into the air on the outside. In doing this, or at any time when robbers are around the door, we kill very few bees, as about the only place where they can be mashed is on the three blocks, $2\frac{3}{4}$ inches

square. Any bees that we don't jar off the door soon find their way into and out of the bee escape at the top.

THE WINDOW-SCREEN.

Our window-screen is made as follows: Two pieces for the sides extend from the window-sill to within $1\frac{1}{2}$ inches of the top, and these are held together with the three crosspieces, $\frac{7}{8} \times 1\frac{1}{2}$ inches. The wire cloth is tacked on the inside of the frame. To make an exit at the top we nail some pieces $\frac{3}{8}$ by $\frac{7}{8}$ by $4\frac{1}{2}$ inches long to the top crosspiece, nailing them 3 inches apart. The lower end of these pieces should be even with the lower edge of the crosspiece. Next lay some $\frac{3}{8}$ by 3-inch pieces in between the upright pieces. Then lay on a strip of wire cloth 4 inches wide; next lay a $\frac{3}{8}$ piece over each one already on, and nail fast, the wire cloth being between the pieces. Owing to the fact that the frame of the screen is $1\frac{1}{2}$ inches below the top of the window, it leaves a space for the bees to pass out between the cleats nailed to the outside of the frame. It will be noticed that this window is close up under the eaves; see Fig. 6. For several years we had a window, the top of which was 20 inches lower than this one. The frame to the shorter window screen was made of pieces $\frac{7}{8}$ in. square. The side pieces extended 8 inches above the opening, and the top cross-piece was nailed on the outside of the side

FIG. 9.—The box complete.

pieces. This gave a bee exit $\frac{7}{8}$ by the width of the window; and with such good light and a large exit any bee that found itself on the inside would work out in a short time. Much to my surprise, the bees never found their way in here when inclined to rob. Our present exit being nearer the eaves, and consequently darker, is much slower to work the bees out. It is an advantage to have all the light possible above an escape of this kind.

UNCAPPING-BOX.

First make a box 6 inches high at the sides, and with the bottom slanting toward the center. Ours was made 15 inches wide and 24 inches long. This box should be lined with galvanized iron, and have a honey-gate in one end, Fig. 7. Next make a box 12 inches deep. Have it rabbeted 7-16 inch square at the lower outside edge, so it will rest down in the tin-lined box. It should have some $\frac{3}{8} \times \frac{7}{8}$ cleats nailed on the lower inside edge. Then make a loose-fitting frame to rest on these cleats, and cover the frame with $\frac{1}{8}$ -inch galvanized wire cloth. This frame should have a center piece to prevent sagging. See Fig. 8.

Next get a piece about 5 inches wide, and as long as the box is wide. Halve this at each end so it will fit in the box snug. Make holes through it to receive the end of the top-bar to prevent slipping while using the knife. See Fig. 8.

FIG. 8.—Closer view of the tray, showing the board across the top, with holes for the projection of the top-bars to rest in.

FIG. 10.—Changes made in the Dewey foundation fastener.

For a stand we take four pieces, 2x2, 24 inches long, for the corners. Next we get two pieces of $\frac{7}{8}$ stuff 10 inches wide, and as long as the stand is to be in width. Nail these to the 2x2, one inch from the end. Next nail two pieces, 6 inches wide and the proper length, to the 2x2, letting the lower edge rest on the ten-inch pieces, Fig. 9.

This uncapping-box was made when we did less extracting than now. We are about to build a larger one on the same plan. The new one will be 2 feet wide by 6 long.

THE DEWEY FOUNDATION-FASTENER.

Fig. 10 shows some changes we made in our Dewey foundation fastener. As the sides were inclined to spread and interfere with the working of the machine we put a piece the right length across the inside, and fastened the sides to it. When we received the machine it was rigged to operate by the foot with a chain. Mr. P. G. Clark gave us the idea of operating it by pressure of the body. Add a piece about six inches wide

FIG. 11.—The fastener, operated by pressure from the body.

to the machine so as to bring it nearer to the body, when a slight forward movement will operate it. See Fig. 11. To hold the machine in place we cut a board as long as our work-bench is wide; then, laying the board on the bench, with one end against the wall, fasten the machine to the board where it is wanted. After a little practice the machine can be operated very rapidly.

Syracuse, N. Y.

MOVING BEES WITH HIVE ENTRANCES OPEN

Nothing Used but Tobacco Smoke to Keep Bees in the Hive

BY GEORGE J. VAN DE VORD

We have a method by which we can go into an apiary, and, within fifteen minutes after lighting the smoker, safely pick up and load full colonies of bees without the labor of fastening a screen over the entrance, ventilating the hive, or previously preparing them in any way, except giving them a moderate smoking. Then we can drive to the new location without danger of having horses, attendants, or passersby stung, and also without the danger of smothering over-populous colonies.

The plan was suggested by the necessity of being able to move colonies in old warped or twisted hives that were difficult to make bee-tight. Then sometimes an old hive will give way on the road; and as the bees are always more or less infuriated by being shut up it takes lively and skillful work with the smoker to avoid trouble with horses; and if such an accident occurs on a well-traveled highway there is a great deal of danger of becoming a nuisance to the traveling public. While it may be a pleasant break in the monotony of life to a disillusioned beekeeper to watch the people frantically scamper away from his load of "pets" whenever by accident they get loose, it adds nothing to the good will that these people bear him or the beekeeping business in general if they are compelled to hustle away or stay and be stung.

Necessity is ever the mother of invention. This part of the east coast of Florida has been enduring a succession of very poor years for bees, and I have often had to move my colonies or lose them. My hives, moreover, were mostly second-hand to begin with, and it is very hard to make them bee-tight. Furthermore, I have had to move with as little loss of time as possible.

After trying different kinds of smoke into, on, and around hives from which bees were coming through various unforeseen

Geo. J. Van de Vord moving 41 colonies of bees, using only tobacco smoke to keep them in the hives.
Mr. Van de Vord has moved bees for over four years without screens over the entrances.

cracks and crevices, I found that smoke having a part of its volume derived from tobacco has a very sedative effect without being stupefying or harmful if not used excessively. When I first tried the plan I risked it on only a small load. Though I did not close the entrances, and though I smoked the bees but a very little before loading them, I found that scarcely a bee flew from the hive during the journey which lasted about two hours; and the few that did were not looking for trouble nor making any. Since that time about four years have elapsed, and I have used the plan several times each year, and invariably it has kept the bees in a very quiet condition, even though they are sometimes severely jolted. The use of the tobacco smoke has furnished me a method of controlling them with the least possible expense of time in preparation.

In June, 1910, I had a double team hauling bees all day in hives with open entrances. We were moving first from my apiary at Ormond to a barge at the river front. Although we drove right up to the apiary, neither the driver nor the horses were bothered by the bees, even though the horses were left hitched up at all times while loading and unloading. The barge was then hauled down the river to Daytona that evening, and stood at the side of

the river facing Beach St. all day. The bees flew freely from the hives on the barge, and gathered pollen all day long, while another team and driver were hauling more bees from Daytona and loading them on the barge. These two sunshiny days in a Florida summer were a thorough test of the tobacco method of control, for part of the bees were Holylands and hybrids, and as vicious as yellow-jackets.

The barge was finally towed down to Ponce Park, the hives being stacked in rows three and four high. At this point we had to tie up for the rest of the night and all the next day, on account of adverse winds and the tide. During the next night, however, the wind dropped; and as soon as the tide was favorable we crossed to the North Indian River and moved down to the new location three miles south of Coronado, where, during the fourth day, the colonies were loaded. The bees began flying freely at once in quest of fresh water; but they were gentle, and not at all inclined to sting. The captain of the tug, although very nervous about the bees, and entirely unacquainted with their habits, volunteered to help in the unloading, and did so without veil or gloves, and without being stung.

The accompanying illustration of an auto truck loaded with bees was taken in May of this year. There were 41 colonies in all,

18 of which were two-story and 23 one-story. On this occasion I went to the apiary that I intended to move, at 8:45 A. M., lighted the smoker, and put in about two tablespoonfuls of tobacco dust and clippings, the rest of the smoker being full of partly rotted sacks. Then I went to each hive and puffed in two or three good strong blasts of this smoke at the entrance. I went around the apiary twice; and then, the auto having arrived, we started to load. The chauffeur was to help load; but he was afraid to go into the apiary on account of a few field bees in the air that were not in the hives when they were smoked, but we were safely loaded at last.

After we were started we moved down to Beach Street, where we were expecting a photographer. While waiting for him to arrive I opened a few hives and lifted out a comb or two to show several interested observers that all those "boxes" were packed full of bees that densely covered each comb, and yet they were not stupefied, as shown by the fact that they flew readily when brushed off with the fingers.

After the picture was taken we went on across the bridge, over the river, and up to Sea Breeze; unloaded the 41 colonies, and were back home within three hours. Before the last of the hives were lifted down from the truck the bees had caught the odor of the sweet bay blossoms all around them, and were commencing to fly very

briskly. I had to use smoke on those in the auto to keep them in, for those already unloaded were fairly tumbling out of the hives and relocating themselves. The strange thing about it all was that they were not cross, even though they had sniffed tobacco instead of the perfume of the blossoms.

I use no tobacco in the smoker for ordinary work in the apiary; and as a word of caution I should like to say it is a mistake to use nothing but tobacco in a smoker, or to blow the smoke into one hive for several minutes, for this makes the bees sick, so that they are in as bad shape as if they had been fastened in and overheated.

Daytona, Fla.

[With an experienced operator in charge, who is really an expert along this line, like our correspondent, and with hives that can not be conveniently and securely screened, we should undoubtedly advise the plan recommended. Perhaps we should go further and advise the use of the tobacco method of control generally; but if the hives are sound, so that they can be quickly and cheaply screened, and if the beekeeper has not had considerable experience, we should feel safer if the bees could not get out. If a three-inch rim is tacked on above the brood-chamber, and water carried along with which to cool the bees of any hive that show signs of becoming overheated, there is usually very little danger of trouble or excessive loss.—Ed.]

Allender's apiary of black bees. Colony X by the fence has produced on the average \$10.00 worth of honey each year.

L. C. Root, veteran beekeeper as well as partner, son-in-law of, and co-laborer with Moses Quinby.
Photographed by Edward F. Bigelow, Sound Brach, Conn.

A COLONY THAT AVERAGED \$10.00 WORTH OF HONEY A YEAR FOR TWENTY-TWO YEARS

BY G. D. ALLENDER

The illustration shows my apiary of black bees, which for gentleness, hardness, and ability to gather honey, have never been surpassed by any other varieties that have been brought into this locality. For instance, the colony in the hive marked X at the extreme right by the fence has been on the same brood-combs for 22 years. During this time it has been fed but once, and, with the exception of two years, has made from \$4.50 to \$28.00 of surplus honey each year—an average of about \$10.00 per year for the whole time. Furthermore, there has been about one swarm for every two years from this hive, on the average.

Kerens, W. Va.

L. C. ROOT AS HE IS TO-DAY

BY DR. E. F. BIGELOW

Under separate cover I am sending what seems to me a remarkably good photograph of our veteran beekeeper and missionary in beekeeping interests, Mr. L. C. Root, of Stamford, Ct. Please note how clearly the photograph shows even the brood-cells. Mr. Root has been doing good work in this vicinity by interesting a large number of people in beekeeping. He talks at various bee-gatherings, and is very active in speaking a good word for the bee naturalists. I count myself as primarily his pupil; and through me quite a large number, as you know, have become interested.

The other photograph* shows Mr. Root teaching a beginner. The man at his left is a workman who, not over an hour before Mr. Root's lesson, went running frantically across the fields stating that no amount of money would get him to go near those things. But this workman was to assist in taking care of the bees, and Mr. Root succeeded in showing him that bees are not such dreadful things as he thought they were. You will observe that he inspired confidence, so that the man came up without gloves or veil, and readily handled the frames. I think this is a remarkable example of taming a would-be beekeeper, who, like the public in general, had held frightful ideas regarding the terribleness of bees.

I wish I could have obtained a "before and after" photograph—that is, it would be interesting to show your readers a pho-

tograph of this man tearing across the fields, and striking right and left, about an hour before Mr. Root took him in hand and showed him that his nervousness and not the bees was his greatest enemy. I recently had a similar experience in teaching a gardener who had never been near bees to go up to the hive and take out the frames, without gloves or veil. It is true my man, unlike Mr. Root's, got stung once or twice, but he had nerve enough to say, "And sure you must expect all those things in a lifetime, and I guess they will feel better when I get used to them."

Sound Beach, Ct., June 7.

MY FIRST ACQUAINTANCE WITH L. C. ROOT BY A. I. ROOT.

When GLEANINGS was started, forty years ago, it was, I regret to say, quite the fashion for bee journals to criticise each other; and not only that, some prominent writers seemed to think that it was right and proper to fill the pages of our bee journals, not only with unkind but unnecessary criticism; and I am sorry to have to own up that your humble servant was given to that sort of thing; and as an illustration I did one thing I shall always regret. While I revered and respected both Langstroth and Quinby (both then living), I criticised father Quinby's hives that were then used largely, and perhaps are still, by a large number of York State beekeepers. They resented this, and took exceptions to A. I. Root and his "new methods," etc. I believe it was at a York State convention a resolution was passed, to the effect that A. I. Root, with his "dollar queens" and "one-pound sections," was doing more harm to beekeeping than he had ever done good. I think it was about this time, or shortly after, that, through the influence of the Holy Spirit, I got a new glimpse of things, and I started out on a new track. One of my departures was to attend a down-east beekeepers' convention. I can not remember now where it was, but I think L. C. Root occupied the chair. During the forenoon I had taken part in some of the discussions, and, as a matter of course, showed a friendly spirit as well as I knew how, toward the good people who had said unkind things about me (which I no doubt richly deserved) only a short time before. At the noon hour I shook hands and had a friendly talk with many of the prominent men present. As the session opened after dinner I had one of my "happy surprises." Our good friend L. C. Root, so far as I can recall, said something like this:

"I am sure I voice the sentiment of at least the greater part of our convention, if

* Cover picture for this issue.—Ed.

not all, in saying we are very happy to have with us to-day Mr. A. I. Root, of Medina, Ohio. We are not only *glad* to have him with us, but I am sure I voice the sentiment of quite a good many when I move that we as a convention give him a hearty welcome; and since we have become better acquainted with him, express regret for the unkind things that have been said in regard to Mr. Root in some of our previous conventions."

If I have not gotten the above correct, I think it was the sentiment of what he said. I was at the time greatly impressed with Mr. Root's ability as an officer, as well as a beekeeper and as a genial Christian character. Since that time there has existed only the most friendly relations between ourselves and the great beekeepers of New York; and I am glad to add that the fashion of having unkind sparring and jangling in print in the bee journals (*American*, at least) has been done away with. I believe all now recognize that we have no room in our journals for personalities—especially personalities among good men.

When a great man dies, a kind Providence seems to have so ordered it that his mantle shall fall on the shoulders of some younger man. This seems to be emphatically the case with our good father Quinby. In an edition of the book, "Quinby's New Beekeeping," published by the O. Judd Co. in 1899, we find the following which we take from the opening words of the publishers' preface:

After the death of Mr. Quinby, the preparation of a new and revised edition of his work, which he had in contemplation, fell into the hands of Mr. L. C. Root, his relative and long-time business associate. This secured the incorporation of Mr. Quinby's latest views and methods, and the introduction of important improvements that had then just been tested, especially that of comb foundation, and the treatise thus embodied the experience of two skilled apiarians. The work was so largely rewritten by Mr. Root that he might in justice have claimed to be its author; but with rare modesty, and in a spirit of reverence to the memory of one who had devoted his life to the advancement and popularizing of bee culture, he preferred to retain the title of "Quinby's New Beekeeping."

AN OUTSIDER IN COLORADO

Swarm Control

BY DR. E. F. PHILLIPS

Continued from June 15

In comb-honey production in the East, all other problems fade into insignificance in comparison with the control or prevention of swarming. The number of colonies that can be kept is limited by the number that can be examined about once a week during the swarming season to do whatever is necessary to keep the bees at home and

working. It is, therefore, unusual to find men with 600 or 800 colonies run for comb honey in a number of outyards. Although some of the beekeepers of Colorado do not agree with the idea, it seems almost certain that conditions are not so conducive to swarming in Colorado as they are in the white-clover region. The usual methods of control seem to be about the same in Colorado as they are in the East. The best practice seems to be to examine every colony once a week for queen cells; and with several hundred colonies in yards scattered over the country this is no sinecure. A beekeeper who is kept busy with seventy-five or one hundred colonies should begin to suspect that he is wasting time and energy somewhere when he learns what is being done in Colorado. It is not exactly necessary to keep the grass worn away in an apiary in order to give the colonies the care necessary.

An important consideration in favor of the Colorado beekeeper is the fact that he is not interrupted in his work by inclement weather to the extent that the eastern beekeeper is. It is rather safe to plan for six days of work a week, with a chance at one more if the beekeeper can persuade himself that his bees have fallen into a pit.

NO WAX MOTHS.

As has been mentioned a number of times, the common wax moths which add interest to the monotony of beekeeping in the East are absent in Colorado. As Mr. Foster mentioned in a recent number of *GLEANINGS*, the Mediterranean meal-moth sometimes eats the pollen from stored combs. Messrs. Dyer and Burrows, of Boulder, brought a large number of colonies from Arkansas not long ago and incidentally imported the larger wax moth. Not being accustomed to thinking of damage from this source they were surprised to find a mass of webs in their workshop where the empty combs were stored. Since then the moths have entirely disappeared. Some entomologists would confer a favor by learning what there is in the climate of Colorado which is injurious to the bee-moth.

BEEES AND FRUIT.

The value of bees in carrying pollen is seemingly quite generally recognized by Colorado fruit-growers, and I learned of a number of instances where a few colonies were kept solely for that purpose. This is gratifying; but at the same time the practice opens up a source of danger to the professional beekeeper. It can scarcely be expected that a beeowner who is not a beekeeper will know how to detect and eradicate disease, and such apiaries may become

a worse menace than the almost universally neglected farm apiary, and almost as bad as that of the enthusiastic amateur. This is well illustrated in Massachusetts, where bees are used extensively in greenhouses to pollinate cucumbers. The practice offers a sale for colonies; but the discarding of weakened colonies is often blamed for the spread of disease. At the same time the awakening of interest in bees among fruit-growers will result in good beekeeping, especially in getting support in asking for new laws.

In most cases, when the loss of colonies due to the spraying of fruit trees is reported, it is safe to suspect that the beekeeper is mistaken. In the majority of such cases the trouble is probably a brood disease, and European foul brood is a safe guess. When such cases are reported, it is our practice to write for brood which may be affected, and it is usually easy to determine the cause of the trouble. However, several cases were reported in Colorado in which rather serious results to bees have followed spraying fruit trees in bloom. There is a State law prohibiting such practice, and in several cases it has been found profitable to use it as a club.

PURE MATINGS.

Apiaries are quite close together in the alfalfa section of Colorado, and pure matings are at least as difficult as in the East. However, there are, not far from the irrigating regions, places in the mountains where there are no honeybees. Mr. Foster informs me that he has seen white clover in profusion with nothing to work on it except wild bees. Such locations in the mountains are usually too inaccessible, and too limited for honey-producing apiaries; but they would make ideal situations for mating queens. This is an idea that belongs to Mr. Foster; but it may have occurred to many another beekeeper near the mountains. If queens can be mated without too great an expenditure of time and money per queen it would be a great thing for Colorado beekeepers if Mr. Foster can carry out his own suggestion in his capacity as State Inspector. The difficulty is that mating is the most expensive part of queen rearing, and many a man who has had visions of wealth from queen rearing has later found him selling queens for less than they have cost him. But we never know how a plan will work if we merely sit by and speculate. It is to be hoped that the plan may be tried.

THE COLORADO HONEY-PRODUCERS' ASSOCIATION.

Probably no phase of Colorado beekeeping has attracted more attention among the

beekeepers of the country than this co-operative association. Not having had much opportunity personally to study the workings of the organization, and not being particularly familiar with the methods of successful co-operative organizations, it would not be wise to discuss the merits of the various phases of the work. However, judging from the sentiments expressed by various beekeepers, and by the satisfaction which seems to prevail among the members, one is forced to the conclusion that it is a good thing, and that beekeepers in other localities would be benefited by a study of the plans of the association. So far as could be seen, there is no peculiarity in the conditions in Colorado which makes success in such an enterprise more probable than in other States. With the largest markets in the East there is the advantage in car-load shipments of a lower freight rate, but this applies equally to other localities.

The organization and enthusiastic management is doubtless largely due to the manager, Mr. Frank Rauchfuss. A question which promptly and naturally comes to mind is, whether the success depends solely on Mr. Rauchfuss or whether the organization would continue in as satisfactory a manner if he were to retire. This question is not of such vital importance to the Colorado beekeepers as long as Mr. Rauchfuss remains on the job; but it is of vital importance to beekeepers in other States contemplating a similar organization. Is it necessary to have a man of exceptional ability, or can any organization of beekeepers expect to find a man of sufficient ability and honesty to make a success of such a movement? Naturally we can not expect Mr. Rauchfuss to volunteer to retire, nor the association to retire him for the sake of answering this important question; but there is such great opportunity for the advancement of the interests of beekeepers by co-operation that the beekeepers in the several States should attempt to decide the question, and this subject should receive careful consideration in all parts of the country.

The association has very materially increased the price obtained by the producer for honey, especially comb honey, and has been instrumental in bringing about greater uniformity in the product and its grading. Sections containing bottom starters of foundation, and with full separators, have the sanction of the association, and the association's grading rules are carefully enforced. Bee supplies are sold at a reduction to all beekeepers, and other commodities are often obtained at a material reduction for members. Wax is sent to be

made into foundation in large lots for members. The association also carries on a local business in bottled extracted honey. These things in themselves are annually worth many dollars to the members; and, in addition, at the end of the year the profits of the association are equitably divided by a unique plan. The organization has been in successful operation for a number of years, and it is high time that beekeepers elsewhere were giving to this subject the consideration it should have. It certainly should be possible for the beekeepers in the best beekeeping States to organize on a business basis.

It should be mentioned that the Colorado Honey-producers Association is entirely distinct from the State Beekeepers' Association. It is obviously necessary to have money with which to conduct business, and unless some philanthropist puts this up it will be necessary for those who will reap the benefits to buy stock in the company. While a beekeepers' association can help its members materially, it is barred from many essential lines by lack of funds, and it will be just as well not to try to have the two organizations in one. If the business organization reduces the efficiency of the other, it matters little so long as the interests of the beekeepers are concerned.

COLORADO.

No normal outsider could write a paragraph on Colorado beekeeping without having something to say about the marvelous scenery. And yet it is utterly foolhardy to attempt a description that will not be a sacrilege. In our 1000-mile trip Mr. Foster and I crossed the Tennessee Pass, and re-crossed the mountains over the celebrated narrow-gauge route by Marshall Pass, passing through Eagle Canon and the Canon of the Grand River going west, and the Black Canon of the Gunnison on the eastern trip. The Royal Gorge was part of a night trip going west; but we came through by day on the return, so that it was not missed. Where there was no special feature to be seen, there was always still enough of interest to excite any but one surfeited with scenery. So many interesting situations present themselves that one is tempted to forget his mission and stop to fish, hunt, or simply enjoy the views. The first trip to the Colorado Mountains should be for pleasure only, so that one may become accustomed to the grandeur before any duties come to distract attention. However, a hurried trip on business infinitely surpasses none at all.

All the world knows that the climate of Colorado is especially exhilarating; but to

know this to the full, one must be there in early autumn. No wonder that those unfortunates who have gone to Colorado on account of pulmonary troubles become so enthusiastic in their praise of the place where health is restored to them. It is almost worth having tuberculosis for the opportunity of knowing the climate. If you get tuberculosis or an opportunity, visit Colorado.

Washington, D. C.

RENDERING PARTIALLY DRAINED CAPPINGS IN A SOLAR EXTRACTOR

A Plan for Getting All of the Honey by Partially Melting the Cappings

BY HENRY STEWART.

There has been considerable inquiry for a method of handling cappings that will do the work better than the capping strainer or melter. I have a plan which I have used for several years, which I consider ahead of either of these. It is a sort of modification of the solar extractor. I call it the *solar honey-separator*. While it is somewhat the same in principle as the regular solar extractor, it does work that can not be done in the latter, and the honey is still in a very good condition as it runs out, as it is only slightly if any impaired. The best feature about it is that it is ready for business any time when the sun shines from May to October, not only for cappings but for odds and ends, broken combs, unfinished sections, etc.

This separator may be built anywhere; but to secure additional reflected rays of the sun it is better to choose the south side of a building. Reference to the illustration will show that A is an enclosure built on a concrete foundation adjoining the south end of my honey-house. It is 44 in. long, 24 in. wide, 36 in. high in front, and 50 in. high at the back. This enclosure is covered by a glass door, the under side of which is lined with felt or woolen cloth around the edges to make it tight. A double glass adds to the efficiency of the separator, although if not too much is expected a single glass is sufficient. To prevent rain water beating in, the hinge side of the glass door should be covered with a strip of oilcloth.

About two inches under the glass is a galvanized iron tank, F, resting on a framework so that it can be removed easily. This is 36 in. long, 14 wide at the bottom, and 18 wide at the top. It is 15 in. high in front, and 20 high at the back. Four inch-

es from the left (west) end is a partition G, which is soldered tight to the sides and bottom of the tank F, except a narrow opening $\frac{1}{4} \times 3$ in the lowest corner. This acts as the separator, as the wax, being lighter than the honey, floats on top of it, and is, therefore, confined to the right side of this partition, the honey flowing over through the narrow slot at the bottom into the four-inch compartment between the partition and the left end of the tank.

A slatted bottom, H, which inclines toward the back of the tank, supports the cappings in the sun, as it is located in such a position that no part of it is shaded.

To catch the cappings from the knife, I use a galvanized iron stock-tank having a slatted bottom above the true bottom, and a honey-gate at one end. The cappings are allowed to accumulate and drain over night. The next morning, with a pitchfork I remove a wash-tubful of cappings from which most of the honey has drained, and dump them into this separator on the slatted bottom. If the sun is not shining very

hot I stir them three or four times during the day as they melt. If the sun is very hot, I shade the glass partially by fastening over the top of it a piece of burlap. As the cappings warm up, the honey and a little of the melted wax drops through the false bottom into the cool shaded portion of the tank beneath, the honey running through as the level rises into its own compartment. The bulk of the cappings remains in a semi-melted state on the slatted bottom. This mass is allowed to harden; and the next morning, by the use of a chisel, it is pried loose and stored away until a convenient time for rendering into wax with the ordinary wax-press.

The honey is usually drawn off while it is warm, into a sixty-pound can, and strained through a wire-cloth strainer at the mouth of the can. The melted wax that drops through the slatted bottom is allowed to accumulate until the time comes for rendering, when it is removed and put through a wax-press with the rest.

Prophetstown, Ill.

ALCOHOL FOR CLEANING SECTIONS

BY S. N. HATHAWAY.

I have noticed that all my late sections are soiled more than those used for the early crop. This probably comes from the natural desire of the bees to chink up every crack and cranny as a preparation against the cold winds of winter. Some swarms seem to try to daub on all the propolis they can make, while others are quite modest in the use of it, even to the last super. I had several supers this week that were so badly daubed that I nearly despaired of making them presentable in the shipping cases.

As I sat thinking how this could be entirely removed in some other way than by scraping so much, I chanced to see a bottle of denatured alcohol. Knowing that it would cut wax and propolis I made a swab by rolling some soft cotton cloth and tying it so as to make it convenient to use as a brush. I applied it freely, and then with a piece of cloth rubbed it off and scraped with the knife. When the sections were badly stuck up I repeated the dose and rubbed it again. It was a success; for when all had been treated, and were in the cases, they were as clean and nice as a newly filled super. This may not be new to the "old soldiers" in the business; but it is new to me, and is a time-saver.

GLASS NOT NECESSARY IN SHIPPING CASES.

It is my opinion that a one-tier 24-section case is the best for all purposes, with only a two-inch glass, if there must be any glass at all. The more glass used, the weaker the case is, and the more cracked sections in the cases. So I say, *no glass*. I think a bottom made of $\frac{7}{8}$ -inch board, cut to fit inside the case, would make it perfectly safe, as there would be no spring to the bottom, and consequently no chance to crack the honey unless the case should be dropped by some careless handler.

If the whole width of the front of a case is glass, a buyer sees but four sections, which may be extra fancy or No. 1; but if the packer is not honest and square, it's a guess as to the rest of the case. My verdict is, *no glass*. Take off the cover, and then you will know what is inside.

Each case should have a printed card, pasted on the top, reading, "Comb Honey, this side up. Handle with care." Following the above should be printed the several grades of honey, all of which may be crossed off with a pencil except the one packed in the case. The weight, tare, and net should be on the same card.

Waldron, Ill.

[You are entirely right in urging no

glass in comb-honey shipping-cases. More and more glass is being discontinued by the large producers, and we hope ultimately it will be a thing of the past. Shipping-cases with solid back and front are much stronger than the glass cases.—ED.]

A SWEET-CLOVER-SEED STRIPPER

BY C. A. BUNCH.

Last fall I made a seed-stripper for gathering sweet-clover seed, which I found very useful. The construction is explained very fully by the illustration. The nails shown in the crosspiece are ten-penny size, driven zigzag about $1\frac{1}{2}$ inches apart. The stripper should stand on a good-sized wash-tub or tight box, and the whole apparatus securely roped to a wheelbarrow.

It takes three persons to gather the seed to the best advantage—one to cut the sweet clover with a sickle, and carry it to the stripper; another to draw it through the stripper, and run the wheelbarrow, and a boy or girl to handle the lever. We gathered four bushels of seed last fall, and the cost did not exceed two dollars per bushel.

When we get ready to harvest the seed we move the whole outfit out to the sweet clover, with a wagon, then proceed to rope it to the wheelbarrow. I do not fasten the rope to the tub, but to one end of the frame, then down under the wheelbarrow floor, and up to the other end of the frame, which holds the whole thing firmly. The rope must be drawn tight so as to make every thing solid, as pulling the clover through under the lever requires considerable strength. It is a good plan to spread a grain-sack or cloth across the handles of the barrow to catch the seed that might fall outside.

Australian Honey Crop Harvested in Kerosene-cans

In reply to a question, Jan. 1, p. 18, the statement was made that if second-hand cans had been used for benzine, they would do to store honey in; but if for kerosene, they would be of no use for the purpose. I think you are wrong. Practically the whole crop of Australian honey is put up in second-hand kerosene-cans. By "second-hand" I do not mean dirty or rusty cans. They are quite bright and clean, but they once contained oil. Many beekeepers purchase them by the thousand at 75 cts. per dozen from the dealers in Sydney and other large cities.

The cans have first to be mended—that is to say, the holes made to get the oil out have to be patched; then the round bung is taken out, and then they are ready for washing. A good solderer will mend 400 in a day; but it takes two boys to wash the same number in the same time. The method is as follows: The cans are spread out on the ground in long lines, about six deep. Boiling soda water is used (15 lbs. of soda to 20 gallons of water). One quart of this boiling soda water is put into each of six cans. The cans are picked up one at a time, and vigorously shaken, care being taken to see that the water gets right around the tin. This water is thrown away. The washer has a pad on each hand, with a piece of cloth next to the tin, and a piece of thick leather next to the hand. He picks up the can so that the pad on the right hand closes the bung-hole, and this pad must be held tight, as shaking practically boiling water generates steam, and if a firm grip is not maintained there is every possibility of getting scalded.

After the soda water the same process is gone through again with boiling water, then they are rinsed with cold water, and turned upside down to drain. After draining they are placed right side up to allow the sun to sweeten them for a day, then they are packed away in an airy shed, and before being used each one is inspected, and if there is any smell it is rejected and washed again; but if the boss is around to see that the lads do their work well there are not many rejected.

The reason for using second-hand cans is one of price. They cost 72 cts. per dozen. The new tins cost \$2.64 per dozen, and they have to be given away with the honey; and as the returns are frequently less than \$1.92 per tin for the honey, you can see that relatively the price of the tin is a big item.

MAJOR SHALLARD

South Woodburn, Australia, April 16.

[See Editorial elsewhere.—ED.]

Using Gasoline-cans for Honey

Editor Root:—In regard to using gasoline-cans for honey, page 18, Jan. 1, are you not mistaken in advising their use? I once drew some gasoline out of the auto into a two-quart Mason fruit-can. It stood in the can for some time, and then it was taken out, and the can thoroughly cleansed and then used for canning fruit. When the fruit was opened it had such a peculiar flavor that we could not eat it. I asked my sister what made it, and she said she had used the can that had contained the gasoline. For this reason I should be afraid it would give the honey a peculiar flavor as it did the pears. Gasport, N. Y., Feb. 27. JAMES H. SPROUT.

[If the cans contained a good grade of gasoline we do not see how the honey could be tainted, but, at the same time, we may be mistaken. Certain it is that bright new cans are none too good for as expensive a product as honey. If kerosene-cans are cleaned as thoroughly as described by Major Shallard, above, they ought to be as good as new.—ED.]

Honey-crop Reports from Southeastern Florida

Reports from the titl region show that the surplus flow there was good. Reports from the black and white tupelo-gum section show that the flow from these sources was either a flat failure or very light, owing to the great flood and the amount of rainfall which occurred during its blooming season. Reports from the saw-palmetto region show that it gave only a very light flow, owing to weather conditions. The flow from the mangrove was not as good as was expected.

Citrus fruit in its region gave the bees a good

start in early spring by a flow a little heavier than usual.

The gallberry gave a good yield in its region.

The flow from chinquapin was very light.

The poplars, or tulip, gave a good flow over the middle and northern portion of its region; but it was very light over the southern portion. The prospects for the flows which are still to come are good.

Cordele, Ga.

J. J. WILDER.

Too Little Room for Candy in the Queen-cages

I notice very little said of the new queen-cage of late. I think many queens are lost by the candy being eaten out too soon. Many times the candy may be half eaten out by the bees when queens are received. If the old cages are to be used I think it might be well to make them as indicated by the

enclosed drawings of the different cages, and then use a comb instead of cardboard.

Worthington, W. Va., Dec. 15. L. H. ROBEY

[The only objections to your scheme of providing more room for candy is the increased weight, and, of course, increased postage. There are two standard sizes of queen-cages. The smaller size is just as large as it can be and still come under the weight for one-cent postage. In the same way, the larger cage is just large enough so that it will go for two cents. Of course, we might redesign the cages, and provide more candy room, and thus use less space for the bees and queen. This, we believe, would be a mistake. The longer the distance a queen has to travel in the mails, the more attendants she should have. But for export cages, the larger size will contain 50 to 60 bees, while the smaller size, for domestic use only, and for short distances, will accommodate 10 bees besides the queen. Taking every thing into consideration, it is our opinion that a piece of pasteboard, so placed over the candy that the bees have to gnaw it for 24 hours to get it away will practically secure the same results as the holes of candy.—ED.]

A Loud Warning to Beekeepers

Mr. Root:—Perhaps you can remember giving a careful warning, well worded and thoughtful, about looking well to harness and wagons. I was proud of your comments at the time; but although I had my harness and rig all right, we never use brakes here; and in coming down hill with a heavy load of

A Dust-proof Showcase for Honey in Shallow Frames

We have a large walnut showcase, formerly used for something else, that now stands in the grocery to hold shallow frames of honey. With its six glass doors it will accommodate 225 frames in each division, 15 deep on each shelf, so 1350 are provided for, and, at 4 pounds each, 5000 pounds can be put away safely, and thus protected against moth and dust. A little sulphur will protect a great many combs, empty or full—5% depth is shown. This case is an object lesson to beginners, and traveling men say that nothing approaching it in size of display have they seen in their travels.

We keep the front attractive, and store surplus combs at the back. It sells honey on sight, and some buy 4 who came for only a section. There was only one year when the crop more than filled it.

BEES HIVED FROM A SKYLIGHT
After unpacking supers of honey in the back room of the store, four miles from the apiary, we had a collection of homeless bees from 60 hives (more or less) that accumulated on an overhead skylight. Rather than lose them a hive with a division in the center, filled with combs of honey, was prepared, the bees were taken down and divided into two lots, and a spare queen given to each. This hive was set a foot from a window, having a hole in the glass, with a stick running up to the hive. The bees climb the same path, and divide to their respective sides, and are now as lively as any bees.

Evansville, Ind.

W. W. VICKERY.

Number of Bees in Nuclei

Gentlemen:—Please send me the following information: What is the weight of and number of bees in a one-frame and also a three-frame nucleus? In a pound package of bees how many are there, measured in bulk?

T. J. JACKSON.

El Dorado Springs, Mo., May 6.

[A one-frame nucleus contains about one-third of a pound of bees and about two-thirds of a frame of brood. A three-frame nucleus contains a little over a pound of bees and three frames of brood partly filled. The number of bees and amount of brood will vary. Sometimes there will be more brood in proportion to the number of bees, and other times more bees in proportion to the brood. A pound of bees will approximate about 4500, which would a little more than fill a quart measure.—ED.]

honey my harness breeching gave way, the load striking the horse, which got away. In falling under part of the load, I got my back partly broken. This was the last part of August, and I have never stooped or lifted since, and never will, likely. After 35 years of steady beekeeping and working up a honey market, and a home trade which will take 10,000 lbs. of honey from our house, I am forced to give up. My honey trade and good will are worth \$1000 cash, for which I shall never get a cent. My conscience has dogged me every week since I got hurt, to warn others. Every wagon used for bees or honey should have *brakes* on. I have never yet put a pound of honey on the market nor advertised or sold on commission. My trade is never filled.

CHARLES MITCHELL.

Molesworth, Ont., Canada, June 10.

Space Above and Below in the Shipment of Bees

We note your instructions in June 1st issue of *GLEANINGS* for shipping bees, which are good so far as they go; but I think that full colonies ought to have 1½-inch space underneath bottom-bars, and 2 inches above the brood-frames for clustering, and something across the top to prevent piling up, so as to shut off the air. No old field bees nor bees having the swarming fever ought to be nailed up. We recently received a bunch from the South practically all dead; not a good frame of brood in the bunch; enough bees for perhaps two nuclei. Express charges were \$30.75. The whole thing can be considered a total loss. I believe a comb of water ought to be added.

Bellevue, O., June 5.

H. G. QUIRIN.

[Your suggestions to have a space above the bees and below them are entirely in order, and we may say that in both carloads of bees that we shipped from the South to the North we had such space. There was also protection above the top of the screen. We thank you for calling attention to this matter, as it is very important to have these precautions observed.—ED.]

Hybrids Stood the Cold Weather Better than the Italians

Out of 210 colonies in ten-frame double-walled hives in Fairfield and Litchfield counties, I lost through the winter and spring 20. Of these, 16 were Italian, of which 6 were from Miller, in Pennsylvania; 6 from Doolittle; and 11 from George E. Hilton. I lost every one of the Italian colonies before March 1, on full combs of honey. They were frozen to death or killed by dysentery. We had three months of zero weather, with no cleansing flights.

Out of the 194 hybrids (half black) I lost 4 from starvation through April. The Italian colonies were in the same row as the hybrids.

Danbury, Ct., May 23.

JOHN NICKERSON.

[Were the Italians goldens or leather-colored?—ED.]

Our Homes

A. I. ROOT

I am come that they might have life, and that they might have it more abundantly.—JOHN 10:10.

They that wait upon the Lord shall renew their strength; they shall mount up with wings as eagles; they shall run, and not be weary; and they shall walk, and not faint.—ISA. 40:31.

Cast me not off in the time of old age; forsake me not when my strength faileth.—PSALM 71:9.

I am starting out, as I have told you several times, to try to live to be a hundred years old. How can I manage it? What shall I do, and what shall I cease doing? Mrs. Root said she had very little desire to be a hundred years old; but when some of the children reminded her that she could probably aid in prolonging my life better than any one else in the world, she added, "With that view of the case I would try hard to live to a good old age."* You see she takes an unselfish view of the matter. Well, friends, I too am trying to take an unselfish view of the matter. I not only want to live to see what is going on in the years to come, but I want *others* to live to a good old age. Mrs. Root has often reminded me that people who live to be up to ninety years or more are usually not only a burden to themselves but oftentimes they seem to be, at least in some respects, a burden on the rest of the world. Now, I think this need not be so. Our good friend Terry insists quite vehemently that it need not be. He too is trying to come up to the hundred mark; and he and I both have been for years trying to teach humanity how to "keep well and live long." One reason why I want to live as long as God's will is that I should live, is that I may see what is being accomplished in this line by our good men and women of this twentieth century.†

May God be praised for the assistance our Department of Agriculture is giving. In my hands are some recent bulletins sent

out by the Department. The titles are as follows: "How to Prevent Typhoid Fever;" "Tuberculosis;" "Facts about Malaria;" "Remedies against Mosquitoes;" "House-flies;" "Harmfulness of Headache Mixtures;" "Poisonous Mushrooms;" etc. These bulletins have all been sent out within the past year or two. There is just one more—"Habit-forming Agents—Their Sale and Use a Menace to the Public Welfare." A lady who gave an open-air address on our public square spoke about the recent legislation or ordinances against impure or deleterious milk. She said the number of babies that lost their lives in Cleveland, every summer, through the use of milk not fit for use was *greater* than the number of people lost on the Titanic. May God be praised for what has been done to save the *babies*; and I hardly need tell you that the mothers of these same babies have had much to do in securing this very just and wise legislation. This pamphlet about habit-forming agents informs us that the babies, through the agency of ignorant mothers, get an appetite for stimulants in soothing syrups, for instance, and things along that line. Later on, different things are put on the market, just to get the pennies from children so young that we might almost call them babies. The climax of this terrible work (just for the sake of the nickels and pennies) is the cigarette business. In the last number of that periodical called *Good Health* we find the following:

Not fewer than 10,000 persons die annually of chronic poisoning with alcohol and tobacco—six times as many as went down with the Titanic.

Well, this government bulletin on habit-forming agents does not *mention* cigarettes, scarcely mentions tobacco, and has not a word to say about beer and other *intoxicating* drinks, although it does have considerable to say in regard to opium, morphine, etc. As a rule it rejoices my heart when I get hold of these government bulletins, especially the reports from our experiment stations. By the way, our Ohio Experiment Station at Wooster is said to be doing a greater work, or at least a *better* work, than perhaps any other similar institution in any of the States. May God be praised for this. I have, however, a report in my hand just now from our Wooster station that did *not* "rejoice my heart" when I saw it. It is entitled "Tobacco Culture in Ohio." I asked the question recently through our journal if the people of Ohio generally

* Mrs. Root not only knows better than anybody else in the world what sort of food agrees with me best, but she knows better how to prepare it. She is also prompting me more or less every day of my life in regard to health measures. Wherever we are she makes provision for my naps before dinner, and exhorts me every little while to straighten up, throw back my shoulders, and expand my lungs. I hardly need remind you that she is almost fierce in this matter of pure air and abundant ventilation. Very likely I should not be alive and dictating these Home papers at this moment were it not for my untiring and indefatigable helpmate.

† I not only want to see what is going to be done in regard to sanitation, pure food, fresh air, etc., but I want to see the outcome of wireless telegraphy, flying-machines, electricity, and radium. By the way, my radium "*still radiates*." The little specimen I have, although it has for years been pouring forth a literal "bombardment of shooting stars," is at it *still*, winter and summer, week days and Sunday. I also want to see those "that wait upon the Lord" "*inherit the earth*."

felt that it was a wise thing to do to have our Experiment Station teach our Ohio boys "how to *grow tobacco*." I am glad to know that at least a few of the professors at our Wooster station are not in favor of experiments in growing tobacco, and, as a consequence, it is not grown on the grounds at Wooster, but at a sub-station in the southern part of Ohio. In a communication from the director of our station, just received, he said something like this: "Mr. Root, while the men of Ohio, two out of three, if not four out of five, are tobacco-users, what else can we expect than that tobacco culture will be taught?"

Now, friends, I think you can get a glimpse of the reason why I have been for long years praying that the mothers of Ohio might speedily have a chance to vote on questions where they are more deeply interested, and where their judgment is better and wiser than that of the *fathers* of our land, as a rule. A very young boy was recently found smoking cigarettes; but when a good lady remonstrated he replied, "My pa smokes too;" and as long as his pa continued to smoke a cigar, it would be hard to persuade the young urchin that it is not the thing to do. Our Department of Agriculture has been sending out bulletins in regard to the different kinds of food. One recently in my hands was in regard to "Fish, Its Healthfulness, etc." Now, why shouldn't we have a bulletin reading something like this? "Beer and Similar Intoxicating Drinks; Their Effects on the Health and Morals at Large?" Then Uncle Sam might give us another bulletin: "Tobacco—Its Probable Effect, Physical, Mental, and Moral, on the People of the Land."* Why do we not have such bulletins? Because the Great American Tobacco Company would not like it. They have got somebody stationed near the head of our government who is continually opposing any "fanatical" attempt along this line; and it is the same way with the rum traffic. Not one mentioned for the presidency has dared to say a word about this. Please notice I use the word "dared," for not one has even so much as dared to *mention* the drink traffic. Have you ever found in the voluminous "Presidential messages" any mention, rec-

ognition, or reference, to this "Great Destroyer"? If the women had a chance to vote, do you think this would continue? Surely not. May God be praised for the good and wise women who would save us from a multitude of ills and disasters if they were only permitted to have a chance. I am now hoping and praying that that time will soon come. Perhaps the dawn is just now before us, when we may see a President who fears God but does not fear the rum power—who will not hesitate about attacking what Hobson called "the great destroyer," in his bold speech in Congress.

Now just a word in closing, in regard to our texts. Obedience to God's commands will not only give us as a nation and as a people longer life, but it will give us the ability to enjoy life; to be more *alive*, and to have life "more abundantly," as expressed in our text. The *Scientific American* is not a religious paper. Sometimes I have thought when they were discussing every thing pertaining to human life and health, and yet carefully avoided any mention or allusion to the rum traffic, that they were quite a good way off from temperance and Christianity—that is, one phase of Christianity. Yet I was pleased to note their answer in their question department where a subscriber asked, "Where is the healthiest place on earth?" Let me explain that the *Scientific American* has been for 60 years, to my knowledge, answering all sorts of questions. No matter how ridiculous, the questioner gets some sort of answer; and in order to save time and space, some of the answers are very brief, and sometimes one might think rather abrupt. Well, they replied to the good brother who wanted to know where the healthiest place on earth is, something like this: "The healthiest place to live is where there are the most churches and church-going people."

The good brother was vexed at such a turn of affairs, and asked in the next issue if the querist editor was such an ass as to believe that the *churches* had any thing to do with physical health. The *Scientific American* came back at him by replying that people who observe God's laws would, as a rule, keep the laws of man; and that law-abiding citizens are, as a rule, a healthier lot of people than those who trample law under foot.

The last of our texts has been to me a comfort, especially as I was approaching old age. Physical strength, energy, and enthusiasm, are great blessings; and when they come to me, as they have been coming for the last few months, I praise God for them more than for almost any thing else.

* Not many years ago one of our Medina citizens, a man highly esteemed, got up in prayer-meeting, and confessed that he had been going blind; but when he cut off his tobacco his blindness disappeared. He broke off, and then commenced its use again, until he decided beyond question that the use of tobacco, and that *alone*, was making him blind, and nothing else; and yet that bulletin of toward a hundred pages, from our Ohio Experiment Station, has not a single sentence that even touches on the matter that the influence of tobacco-using has on the health.

A few days ago I was in a hurry, as I wanted to catch somebody before he got out of sight. I started off on a run, a good deal as I used to do when a boy. I caught my man, delivered my message, and commenced to walk back deliberately. Some old farmer on a wagon (I do not know who he was) said, "Mr. Root, it rejoices my heart to see you able, at your age, to start up like that and run like a boy." I told him it rejoiced my heart too, every day, and I was thanking God for it; and I hope that the beautiful text may induce a lot of my old friends to have more faith in Bible promises, to strive harder to obey God's laws, and to hold on to physical strength as long as possible. We must not let the idea get hold of us that we are getting past usefulness. Good sense, aside from Bible teaching, should prompt us to eat sparingly and to be sure to take plenty of physical exercise in the open air every day of our lives, whether we feel like it or not. The old saying,

Satan finds some mischief still
For idle hands to do,

will apply right here to elderly people who are liable to get the idea that they are too old to do some useful work, or that they do not need to work any longer, etc. That beautiful promise, that we shall "run and not be weary, and walk, and not faint," is not to people who sit still and do nothing, even if they are growing old.

SUNDAY EXCURSIONS, ETC.

I presume the great wide world, or at least a great part of it, will continue to laugh and make fun of me because I persist in believing that God's wrath falls on those who forget to "remember the sabbath day to keep it holy." During a Sunday excursion at Buffalo, on June 23, so many people piled on a wharf where the steamer stopped that the whole structure went down in twelve feet of water. I want to give you a newspaper heading clipped from the *Cleveland Plain Dealer*:

BELIEVE 40 DEAD IN NIAGARA CRASH; SEARCHERS
RECOVER SEVENTEEN BODIES WHERE DOCK
COLLAPSED; PARK EMPLOYEES REFUSE TO
AID RESCUERS, AND DRUNKEN MEN
HINDER

Now read the following paragraph:

EMPLOYEES REFUSE TO AID.

There was considerable disorder at Eagle Park after the accident. Employees of the place refused to lend any aid to Dr. Stocker, the deputy medical examiner, in his efforts to recover bodies, and his investigations were hampered by drunken men. No representative of the sheriff appeared, and Dr. Stocker finally ordered all the bodies sent to Buffalo as rapidly as they were recovered.

From the above it would seem that the physician, when he arrived, was hampered

by the drunken crowds—too drunk to care whether anybody lived or died. A list of those who lost their lives is significant from the fact that about nine out of ten of them were women. It has been frequently commented on that the women far outnumber the men in most of our churches; but may God forbid that the women shall outnumber the men in *Sunday excursions*. Perhaps one explanation of this state of affairs is that, unlike the Titanic tragedy, the men here took care of themselves, and let the women struggle and die.

By the way, there are just now several reports of women being drowned because the new-fashioned hobble skirt would not permit them to make a rational effort to save themselves. In fact, a young woman who was an expert swimmer has just lost her life in our nearby Chippewa Lake because she was so hampered by her modern skirt which prevented her from using her limbs at all. Of course, as a rational reason for the loss of life on this and every other Sunday catastrophe, the crowd who had no regard for the sabbath was composed largely of a class like those described in the clipping; and it is a risky thing for both life and limb (to say nothing of morals) to be found in such a crowd.

If you think I am "superstitious" in insisting that more accidents happen on Sunday than on week days, read the following, clipped from the *Cleveland Plain Dealer* of July 2:

Judging by the number of fatal accidents that occur on the first day of the week, a safe and sane Sunday is strongly demanded.

This is not the first time the *Plain Dealer* has uttered similar sentiments, especially after a long list of accidents and fatalities *Sunday after Sunday*.

Later.—Since the above was taken from the daily papers, I learn from a periodical published near the scene of the accident that the number of lives lost was about 40, many of them having been swept by the rapid current over the falls before there was a chance for rescue.

SHALL WE PUT TO DEATH THE INTOXICATED
MAN WHO COMMITS MURDER, AND AL-
LOW THE MAN WHO SOLD HIM THE

DRINK TO GO SCOT FREE?

The following letter has presented the matter of capital punishment to me, at least, in a new light. Read it:

Vengeance is mine; I will repay, saith the Lord.
—ROMANS 12:19.

A. J. Root.—Referring to the article in *GLAD-
INGS*, page 119, I doubt not that the paramount ob-
ject of our lives is that we may so live as to become
promoters of the Redeemer's kingdom among men,
and that we alike deplore the depravity and unre-

generate state of very many of our countrymen. That good, industrious, and useful citizens must and do fall at the hands of lawless and wicked men brings a deep and heartfelt lamentation, not only from each of us, as of one man, but also from every law-abiding and peace-loving citizen our country over. Again, we are as one in our belief that, behind this and almost every other form of vice, crime, and misery, stands that monster of evil, the American saloon—the blight of our nation and parent of nine-tenths of the poverty, wretchedness, and woe that pervade so many hearts and homes. Of the truth of this I am fully persuaded; yet from the introduction of the article from the *Chicago Advance* there is room for the inference that we as Christian believers have been somewhat differently impressed by parts of the New Testament teachings. Now listen: The people of this great nation tolerate laws which license a certain class to dispense to our sons—the young men of our fair land who ought to be the pride of our homes—this poison which debauches, debases, and ruins both the bodies and the souls of these children of fair promise. Now, as this infamous business progresses toward its culmination, where every passion has been inflamed to its utmost; when some heart-rending blood-chilling deed has been perpetrated, then it is that this same people again assert themselves with another law; and in effect they say, "Now hand over to us this poor unfortunate culprit who fell under this snare of his soul's enemy; we will cap the climax by taking away his life, and dropping him out of time—consigning his poor sin-laden soul, not to the fellowship of the saints but to an inheritance among those of whom it is declared they have no part in the kingdom of heaven." Now, what have we accomplished? We have not restored to the bosom of his family the one so brutally murdered. We have conferred no dowry on the widow and her children, nor have we in any degree mitigated their sorrows, but we have made an exhibition of a spirit, not of him who, in the agonizing hour, prayed, "Father, forgive them, they know not what they do," and who said, "If thy brother trespass against thee, rebuke him" (not kill him); "and if he repent,

forgive him." May you and I, dear friend, stand as with our armor on, contending for the right; may we, under the divine blessing, be made instrumental in hastening the coming of that time when "the knowledge of the Lord shall fill the earth as the waters cover the sea." But let us not assume that prerogative which belongs to God alone. No, brother, we who "can not make one hair white or black" may not take away the life we can not restore. We will "rebuke" them, not kill them. But detain them in solitude and servitude till that time when infinite goodness shall sever the tender thread and consign to such place as unalterable wisdom shall decree. Then will our hands be clear of the blood of all men; time will have been given for repentance and forgiveness, if such be yet possible.

Much might be said regarding the evils resulting from executions; but such is not the purpose at this time. Suffice it to say, men whose passions have been so inflamed pay little heed to the punishment that may follow, and perhaps it may be more the certainty of its infliction than its character that deters.

Barnesville, O.

THOMAS DEWEES.

I confess the above has given me a new suggestion. On the impulse of the moment I would say no. Do not put to death any more men who commit murder under the influence of drink; but if anybody is to be electrocuted, let it be the man who *sold* the drink. I have asked the question whether there are fewer or more murders where capital punishment has been abolished in the different States of the Union; but I have not yet seen a conclusive answer. I wish to thank our good brother for his able letter that, without question, was inspired by the spirit of the Master.

Poultry Department

NATURAL-HEN INCUBATORS; HOW TO GET GOOD-SIZED DUCK EGGS, ETC.

My Dear Mr. Root:—In GLEANINGS for June 15 I find the poultry department unusually valuable, not because of the quantity of the matter you use, but the quality of it. That ancient but profitable fraud, the "natural-hen" incubator is treated in exactly the right manner. I wrote an article at least twenty years ago describing exactly the same thing, and I got my plans from some one I had seen in my travels, I now forget where. If there is any patent on such arrangement it is on some insignificant detail that adds nothing to the effectiveness of it.

The longer I keep Indian Runner ducks the better I like them. Have you noticed that they are about the most intelligent of all our fowls? Mine are allowed to run at will, during the time they are out of their yard, in the irrigating ditches on the ranch. They frequently go to the further limits of the place; but at any time in the day if I go out and call them, and they hear me, the ducks answer; and in a few minutes they come as fast as they can for the house. I invariably give them something to eat when they get home. At night they always come up; and when I go out to the yards they stand around and "talk" to me and follow at my heels until I give them their regular night feed. They go into their yard and stay there contentedly until they are released the next day. They are ravenous eaters when confined; but when they have the run of the ditches they do not eat overmuch. Mine prefer a mixture of bran and shorts with beef scrap added. I can stop them from laying in a week by cutting down their feed and reducing the size of their eggs by underfeeding. So far as hatching in an incubator is concerned, I will say that I have just had a hatch come off that satisfied me very well. I had 62 eggs in the incubator, and every egg but three start-

ed to hatch. They went along all right until a week before they were due to hatch, when I filled the lamp, turned the flame up rather high, and *forgot it!* I also forgot to close the cellar door which opens to the east, and the morning sun shone directly in on the incubator. I went out to see about a field that was being irrigated, got busy with a flood of water, and never once thought of the incubator until noon. Then I found the temperature 110 degrees, and said to myself those ducks were cooked, sure. However, I did not give them up, but let the machine run its course. The ducks began hatching the 26th day, and by the end of the 27th I had 36 ducklings, 34 of which were all right. One was a cripple, and I killed it; and the other was weak, and died before a day old. The others are in fine condition now. I examined the eggs that did not hatch, and found three infertile and the remainder with ducks dead in the shell, apparently having died about the time I ran the temperature up on them. As a rule my poultry gets my first attention; but when an irrigating ditch breaks, the results may be serious if the break is not attended to at once. I have very good reasons for believing that a good incubator, supplied with an abundance of moisture from the beginning, will beat a hen or duck as a duck-hatcher.

The cause of blood-streaked eggs is usually overfatness, which weakens the blood-vessels of the ovaries, and they break, exuding a drop or two of blood which follows the yolk down the egg-passage, and becomes incorporated with the white as it is formed. The "bloody piles" described is prolapsus, caused by weakness in the muscles on the egg-passage. Hens in which this condition appears should be killed.

Peotone, Ill., June 22.

MILLER PURVIS.

We are very glad indeed to get the above indorsement, both on the incubator and the

way to get big duck eggs, etc. If a three or four pound duck is going to produce a good-sized egg every day, and, in extreme cases, *two* in a day, good common sense teaches that she must have an abundance of the very best and most nutritious food; and I for one can not see why ducks during the night may not have easy access to all the corn they can consume. To head off the rats and other animals, put their supplies of corn under water each night as they are shut up. Where they have the run of a stream of water, as ours do, the beef scrap is not needed, and the bran and shorts ration can not well be given liberally without danger of rats. Besides, there is no better egg and meat than "corn-fed" eggs or meat. I am glad to have friend Purvis tell us something about his mishaps as well as his successes. His closing sentence indicates there are two kinds of blood-streaked eggs—blood on the inside of the egg, and blood streaks on the shell. The latter can be washed off, but it is some trouble.

BLOOD-STAINED EGGS, ETC.

Mr. Root:—C. F. Childs, in your last number, page 392, speaking of blood-stained eggs, asks for a remedy. A while back, when I had quite a few hens, I had the same trouble, and talked with a poultryman about it. I followed his advice, and in a week or so had no more trouble. Like Mr. Root I can not say whether this would be considered "according to Hoyle."

In the drinking water I put old nails, or, rather, in another dish, and mixed the water I gave them with this iron solution. Tincture of iron probably would be as good or perhaps better. The iron rust has a tendency to strengthen the egg receptacle, and generally giving tone to all the hens in other ways—at least no harm can be done, and it is a good tonic for man or beast. I like a little of it myself.

Cleveland, O.

R. V. MURRAY.

As all of our poultry-yards in Florida are supplied with water through common iron pipes, I can hardly think there is any lack of iron. In fact, when the water comes through the iron pipes, drop by drop, a sort of iron rust accumulates more or less in the drinking-vessels. I notice by some of the poultry journals that mention is made of blood streaks *inside* of the egg. I have never had any thing of the sort. It is blood streaked on the outside that we have been considering, if I am correct.

FLORIDA IN THE SUMMER TIME, ETC.; THE INDIAN RUNNER DUCKS UP TO DATE.

Mr. A. I. Root:—The ducks are doing finely, except one, which was injured by a dog about ten days ago. When I got to the yard where the 26 should have been, about 8 in the morning, I found only two there. I went down to the lower gate and found a dog in the creek after the ducks. The dog was with Mr. R. Knight's cattle, which he was in the habit of following. I went around by the bridge and drove him and the cattle away, and sent Herbert to see Mr. Knight, who promised to take care of the dog; but I am afraid the duck will die. I have caught quite a number of late, and one skunk. The day before the skunk finished up those little chicks I tried to find a trap, but failed. After the

chicks were all dead I found a trap in your tool-house, and set it in the coop with the dead chicks. About nine o'clock that night the whole neighborhood knew that a skunk was in trouble. Raymond put him out of his misery with a charge of shot next morning. Since you left, the three old ducks have laid in 52 days 114 eggs, and one of the 11 young ones began to lay May 22, and has laid four to eight eggs a week since, about the size of a small hen's egg.

The ducks have not been out in the stream for a week, on account of the heavy rain that has converted the stream into a raging torrent. A week ago the ducks would not try to cross the water to get into their yards, so Reginald had to get into the water and drive them up two or three rods above, and then rush them into the water. After several failures he succeeded in getting them all across. The next day the water was nearly knee deep on the bank, and washed over the fences, crowding them over so that there was danger of the ducks being washed off into the torrent. I tied the fences with cord to the opposite side, and have kept them all in so far. There is no danger of their going into the flood willingly. They are afraid of it.

The rain began on the first, and continued until the 11th, most of the time very heavy. Sixteen inches fell in that time. The ducks now get nothing from the water, so I do not expect them to lay many eggs until they can get out again. I was afraid the fiddlers would be carried away by the torrent, but the other day, at low tide, I saw a little *lank o. sand*, a few square feet, covered by thousands of them.

That old duck of yours wanted to sit about three weeks ago, and when Reginald turned the door of her box to the fence she sat on the sand, so we turned her into the water and shut her out, two days, and she gave up and began to lay again in ten days. People who have lived here 30 years say they never saw such a rain before. As a result of the unusual rain fall, the bridge is a wreck, and the road between here and Manistee Ave. is impassable, so teams have to be driven west to Sarasota Ave., and then north to Manatee. But we are to have a steel bridge soon.

C. A. MORGAN.

Later, June 19.—The duck recovered. The old ones are laying about the same; young one also; four to-day; weather fine ever since our 22-inch rain.

C. A. MORGAN.

Bradentown, Fla., June 12.

THE FLORIDA EVERGLADES; A BRIEF REPORT FROM A VISITOR THERE.

Mr. A. I. Root:—On the occasion of my visit to Bradentown in March you expressed a desire to know what I thought of the Everglades after seeing them. Last month my friend Mr. Everett and myself made a trip across the State in a small launch. We were 16 days on the trip.

Leaving here May 8 we ascended the Caloosahatchee River to Lake Hiopchee, then across it through three miles by canal, across Lake Okechobee, to the hotel at the mouth of the south (Miami) canal. We had had an accident, breaking our propeller shaft. The only place to get any repairs was at a dredge, so we went 16 miles down the south canal to the dredge Hiopchee. However, this gave us a chance to see the country.

The soil is deep muck, pure black. We stopped at Mr. Bryant's place, five miles out. He had several kinds of vegetables growing—beans, sweet potatoes, and strawberries. But his sugarcane seemed to make the most remarkable growth. No fertilizer was used.

At the Callahan place, on the south shore of the lake, quite extensive experiments have been made. He had a nursery of grape fruit and orange trees, bananas, vegetables, red clover, alfalfa, rhodes grass, etc. They looked healthy and thrifty.

It is 64 miles from the lake to Fort Lauderdale. For perhaps half a mile from the lake the custard apple thrives. Beyond this, for perhaps 30 miles, one can see nothing but sawgrass. Of course, it appears absolutely level. Two dredges and the drill boat are working above the dam, and a suction dredge below. The dam is 28 miles from Ft. Lauderdale.

The glades are being cultivated along the canals about 6 miles out on the north, and 14 miles on the south canal.

The colony at Zona, on the South Lauderdale canal, appears prosperous. They have a canning fac-

tory to care for surplus fruit. Large quantities of beans, tomatoes, potatoes, and celery were shipped this season.

We were up the Miami canal several miles. There is not much doing there yet.

And now for my conclusions. The land is rich.

It will be drained. It will require fertilizer for best results for some crops, because deficient in certain elements. Its drainage is a big job, and will require some time yet. It is not all surveyed. The water is healthful for drinking, but tastes a little of the soil.
Olga, Fla., June 21. WM. SNYDER.

Temperance

OUR CHURCHES AND THE LIQUOR TRAFFIC.

I have already had something to say about the efforts of the Baptist Brotherhood of Cleveland (God bless them) in their efforts to have law enforced in regard to having saloons closed on Sunday. I am glad to know that the Congregational Brotherhood not only endorses the Baptist movement but are doing something themselves along that line. See the following:

"We are in the fight against saloons keeping open on Sunday to stay," said W. H. Whitney, president of the Congregational Brotherhood, in an address last night at the East Madison Avenue Congregational Church.

A civic committee composed of members from brotherhoods of different denominations is prosecuting violators of the Sunday-closing law.

"Obedience to the law must prevail in Cleveland," said Whitney. "The city won't help us. People must realize that law is more important than success in any political party. The laymen must help in the work, and not leave it all to the ministers."

And finally I said, "May God be praised" when I saw the following heading in the Cleveland Press for May 3:

PRESIDENT IS ASSAILED BY METHODISTS; GENERAL CONFERENCE DENOUNCES TAFT BECAUSE HE DID NOT PREVENT WILSON'S ACTING AS BREWERS' CHAIRMAN.

May the Lord also be praised for the following resolutions which, we are told, were adopted amid cheers:

Whereas the President of the United States, the Secretary of Agriculture, and the Secretary of State, his authorized representatives, were petitioned by the millions of Christian people of the nation, individually and through their respective representatives, to desist from all national indorsement of said brewers' congress, and that the Secretary of Agriculture decline said position of honorary chairman because of the indorsement such position would give to the business represented, and the evident purpose in view by said meeting, viz., to increase and extend the sales of beer and thus encourage the increase of drunkenness; and

Whereas the said United States authorities utterly disregarded the expressed wish and prayer of the Christian manhood and womanhood of the nation, with the exception that the Secretary of Agriculture sent out in reply a most frivolous, fallacious, and stereotyped excuse; and

Whereas the reply is an insult to the intelligence of Christian people, inasmuch as the writer must have known that the sole and only purpose said congress had in view was to secure the seal and approval of the United States authorities to their part in the beverage-liquor traffic, which is the greatest curse and blight to the nation;

Therefore, be it resolved by the general conference of the Methodist Episcopal Church, in conference assembled, that, while we pledge ourselves to remain loyal citizens of the United States, and to support those in authority in every laudable, lawful, and legal way, we do hereby announce as our conviction that in so aiding the beverage-liquor traffic by their persistent endorsement of the said brewers' congress in the face of our most earnest protest, those in authority have forfeited all claim and future franchise of the Christian and sober manhood of the nation.

God grant that every other Christian denomination may unite with the Methodists and indorse the resolutions as above.

"PREVENTION BETTER THAN CURE."

I have had considerable to say on this subject of late; but the following, clipped from the *American Issue*, pointedly directs our attention to a fearful thing that is going on and on in our United States of America, and for that matter, more or less, in the whole wide world. Read it and see if you do not agree.

VOICE OF THE LAND. WHY NOT REMOVE THE CAUSE?

New York is spending hundreds of thousands of dollars for a sanitarium for inebriates. Agitation is on for similar institutions in Pennsylvania and other States. At the same time, commonwealths are spending vast sums in reform farms, penitentiaries, and other penal institutions. But why not prevent crime instead of punishing it? Why not devote time, money, and energy to keep the youth from becoming criminals rather than in taking care of them after they become criminals? Why not remove the cause rather than continue to burden taxpayers with the effect? Why not grow good citizens instead of bad ones?

Now, the saddest part of the above is that not one of the candidates for the presidency of the United States—that is, one with any prospect of election—dares open his mouth in regard to recommending prevention as being better than cure. In other words, we have not had a president's message for many a year, if I am correct, where he even touched upon the question as to whether the *prince of all evils*, that afflicts all nations, shall continue his reign or not. I am watching and praying for the time to come speedily when all good men and women will rise up in their might and demand a president who fears God, but does not fear the liquor power.

LAW ENFORCEMENT WHERE IT STRIKES THE LIQUOR DEALERS.

I clip the following from the *Cleveland Plain Dealer*:

Another obstacle in their campaign against the saloons of Cleveland was encountered by the Baptist brotherhood yesterday afternoon when Chief Prosecutor McKay, of municipal court, flatly refused to issue warrants against two saloonkeepers who, the Baptists said, had violated the Sunday closing law.

Attorney John A. Chamberlain, of the brotherhood, applied for the warrants. He presented affidavits purporting to show that the two saloons in question had been open on Sunday.

In refusing issue McKay told Chamberlain that, if every request for a warrant was granted, half the

population of Cleveland would be in jail most of the time.

The "chief prosecutor" says, in other words, if a warrant was granted for every trifling(?) offense, like *keeping a saloon open all day Sunday*, "half the population of Cleveland would be in jail most of the time." I think I recognize Roosevelt's good qualities, and I believe he is strong on "law enforcement;" but when I vote for a President again, God helping me, I will try to vote for a man who has the courage to insist on law enforcement, even when it runs up against the brewers and distillers with their millions. May God bless, guide, and sustain the Baptist Brotherhood, and may all other denominations fall in line, and back them up.

THE RISE AND FALL OF NATIONS.

On page 64, Jan. 15, I asked the question, "Why can we not have Hobson for President?" Now to-day a printed speech delivered by him in the House of Representatives, Feb. 2, has just been put into my hands. The speech occupies 16 pages. From the first page I quote as follows:

ALCOHOL IN HISTORY.

History is a record of a sad procession of world tragedies. Nations and empires in turn have risen to greatness only to fall. Before the deathblow was struck from without, the evidence shows in every case the ravages of a titanic destroyer within, under whose operations the vitality and strength of the nation were submerged in a general degeneracy.

For centuries the world's philosophers and historians have looked on appalled, overwhelmed. Only in the last few years has science taken up the question. Following her patient, rigid methods, under which nature and life have slowly yielded up their secrets, science has at last cleared up the mystery and identified the great destroyer as alcoholic poisoning.

If you think the above is extreme, read the pages that follow. Now let me quote another extract from the last page:

THE SPIRIT OF THE MEN.

The enemy by ruse attempts to shake the spirits of our forces by saying, "Prohibition does not prohibit." Let us not only show up how it does already prohibit to a marked degree, but let us realize that getting prohibition is but part of our war. The second part is its enforcement. Let us turn the whole power of our organization throughout prohibition territory into such complete enforcement that all the world must see. Shrewd word is also passed along our ranks, especially to the worrying, that "Prohibition can not prohibit." Let us fling this back in the teeth of the enemy. It is nothing less than a boast that the nation is already lost. Let us put it before our ranks as the cry of pirates who have boarded the ship of state, and with jeers are trying to hoist the black flag, with its skull and crossbones, above the Stars and Stripes.

Let me quote from the above. The oft-repeated expression, "Prohibition does not prohibit," is really, as Hobson says, "a boast that the nation is already lost." When you hear anybody say again that prohibition can not prohibit and prohibition can not prohibit, consider that this means virtually to say that our just and righteous laws can not be enforced. That is what the mav-

or of Cleveland said in regard to shutting up the saloons there on Sunday. If that is true, our nation is already lost. And, dear friends, the responsibility rests on you and me to say that our just and righteous laws shall be enforced.

"RATTLESNAKES"—SHALL THEY BE TOLERATED IN OUR HOMES?

My daughter, who is a teacher in the public schools here, came to me and handed me a list price requesting me to send for the *Review of Reviews* for her. I looked up an advertisement I had seen, offering to send this and two others, *Success* and the *American*. I think it was, for about the price of the *Review*. I took all three. When they came I found two of the trio were carrying liquor advertising.

Now, Mr. Root, I should like to have you believe me when I tell you I had rather see a man offering rattlesnakes for sale than to offer liquor, as but few persons would be bitten by the snakes, as they understand the deadly character of such reptiles; but as to the "snake of the still," alas! there are too many who are deceived thereby.

Can not GLEANINGS give us a black list of all magazines and farm papers that carry these whisky advertisements, so that the unwary, like myself, need not be trapped into subscribing to such papers? I do not even want them to come into my home. Possibly you would not like to make up and publish a black list. Well, you could make up a white list of those like GLEANINGS, *Practical Farmer*, etc., that set their faces against furthering the well-being of any periodical that will help the Devil in such work.

If you can not give us a long list at once, give us a small one, and add to it as you become better posted. Send a copy of such list to other publications that you have reason to believe would be glad to publish it. This move would not amount to much at once, but it would soon bring about a line up that would soon compel every journal to show itself on one side of the fence or the other.

To put the matter plainly, there is now no means for a person in the country to ascertain the standing of any paper on the temperance question without investing blindly, and then getting something he would be ashamed to have a Christian person see in his home.

Ozark, Mo., Dec. 4.

S. S. LAWING.

TOBACCO-GROWING IN OHIO.

After what I said in regard to the above in our issue for June 15, I submitted the matter to my good friend the director of the Ohio Experiment Station. Below is his reply:

..Mr. A. I. Root:—You can not be too emphatic in condemning the wastefulness of the tobacco habit; but the facts remain that at least two men out of three, probably four out of five, are users of tobacco, and that the production of tobacco is recognized by custom and by law as being as legitimate a branch of agriculture as the production of corn or wheat.

As long as this is the condition of public sentiment, an institution supported by the State, and conducted for the benefit of the agriculture of the State as a whole, can not refuse to consider the production of tobacco, merely on the ground of personal detestation of the use which is made of it.

CHAS. E. THORNE, Director.

Wooster, Ohio, June 18.

I think I have heard somebody say in times past that "facts are stubborn things;" and I suppose my good friend Thorne is right. But may God be praised that the number of good sound business men of established reputation, who do not use tobacco in any form whatever, is daily increas-

ing. Whatever may be said in the way of criticism, just now especially, in regard to Mr. Roosevelt, let us keep constantly in mind that he does not use tobacco in any way, and, as we are told, he probably never will. And even if what Professor Thorne says is true, as I look abroad and see what the churches, the Y. M. C. A., the Endeavor societies, the Salvation Army, etc., are doing for the youth, not only of our blessed land, but for the whole wide world, I fell like bursting forth in the words of that grand old hymn:

Hail to the brightness of Zion's glad morning;
Joy to the lands that in darkness have lain;
Hushed be the accents of sorrow and mourning—
Zion in triumph begins her glad reign.

Just here my stenographer suggests that the growing of poppies for the production of opium is not so far out of the way as an illustration. And yet "heathen China" has mown down her poppies, in spite of their "poppylarity," and has imposed a penalty for those who still persist in their cultivation that I hardly dare put in print.

TOBACCO CULTURE—SHALL IT BE TAUGHT BY OUR EXPERIMENT STATIONS TO THE YOUNG MEN OF OHIO?

After my remarks in regard to growing tobacco in Ohio, p. 390, June 15, were printed, I found the following in the *Practical Farmer*, written by our good and wise friend T. B. Terry:

Our telephone company has a board of five directors, besides secretary and treasurer. The capital employed is nearly \$30,000. Our national bank has a board of four local directors and two cashiers, and they have the care of about one quarter of a million of other people's money. Now please notice, my young friends: Every one of these officials, from presidents down, attends church. There is not one of them, so far as I know, who drinks any intoxicating liquor. There are not more than two or three, I am told, who use tobacco in any form. Although an officer in both institutions, I have never yet seen these men either smoke or chew. Would that I could give you a clear record on tobacco-using, instead of one slightly clouded. All this is told you so you can see what sort of men are called to positions of trust in our community. And you will find it is getting more and more this way the country over. Young men with sound healthy bodies and clear brains are in demand. The poisons from liquor, tobacco, and overmuch food, in a measure stupefy the brain of any man. He is not so clear-headed as he might be. A large army of young men will graduate from college or high school this year. Others, with less education, will be starting out for themselves. We earnestly beg of you all to start rightly. Don't touch any tobacco or liquor.

ENTERTAINING ANGELS UNAWARES, ETC.

Dear Mr. Root:—I have read GLEANINGS for 25 years, and found much spiritual food in it, especially in Our Homes and Temperance. But to-day, when reading page 63, I find a letter from Mr. Cohenour, that is very indigestible. I won't even swallow it. In behalf of the Scandinavian race I want to protest against it. I am one of the hundreds of

your Scandinavian readers, and I think there is not one of us, not even one in the whole Scandinavian race who deserves to be classed among Eskimos, Chinese, Hindoos, and Pecheras of South America, even if we do eat fish once in a while.

As a contrast to the "fish-eating Norwegians," Mr. Cohenour put the Americans as a superior race, living on mixed food "like birds on bugs and worms until they are grown up." I want to say frankly, if the American in any way is a superior race (it is hardly proper to call them a race) their superiority consists in living on bugs—humbugs—and worms imported from China, Japan, Hindostan, and other countries.

As to the fish-eating people of Norway, I can inform Mr. Cohenour and other ignorant Yankees that the people in Norway do not eat more fish than people do in America, proportionally. The Norwegians are not afraid of getting wet and cold, and they may fish more than the Yankees; but most of their fish are shipped to England, America, and Germany.

I have lived in Norway 30 years and in America 39 years, so I know a little more about it than this shining jewel, Mr. Cohenour. As to mental strength, I think (and every educated American knows) that the Norwegians stand on a full level with any nationality; and as to physical strength you will find a greater number of centenarians in Scandinavia than you can find in America's ninety millions; and some of them would easily come out victorious in a tug-of-war with a 70-year old humbug-eating Yankee.

Yes, I have, in the last 25 years especially, seen hundreds of occasions similar to what this German boy, Mr. Bernhard Kunz, tells us on page 29. These superior Yankees have no use for the foreign worms, if they can't squeeze dollars out of them.

Please let us all try to live up to Paul's teaching in Rom. 12:3 and elsewhere.

Tacoma, Wash., Feb. 1.

E. O. TEFFRE.

My good friend T., I humbly beg pardon for allowing the expression you refer to to get into print. We should all remember that here in the United States, "the land of the free and the home of the brave," as we are wont to call it, we are made up of *all* nationalities. We have bright boys and men who came from *all* quarters of the earth; and we should all be careful about making use of any expression that will reflect on our neighbors. Friend Cohenour used the expression he did because he was a little vexed, as I take it, because I suggested that he, with a large family, might make ends meet by living on "boiled wheat." He resents this, and declares that neither a vegetarian diet nor a meat diet will produce great men of superior education. In speaking of fish, let us remember that the great Master, when he made his banquet for his beloved followers, gave them first a fish broiled on the coals; and after that, honey in the comb. In view of this, who can think of casting a slur on a nation, the inhabitants of which use a large quantity of fish as food? Our stenographer suggests that friend Cohenour does not refer to the Norwegians as we know them, but to the inhabitants of the northern part of Scandinavia who necessarily use a large quantity of fish. He contrasted the Hindoos as vegetarians with other nations who use meat almost exclusively, in order to prove that a mixed diet is better.

NO. 15

Editorial

THE FRONT COVER PAGE OF THIS ISSUE.

The front cover page of this issue shows a characteristic apiary seen on the mountain sides in California. The picture was originally taken by Mr. W. Z. Hutchinson. The locality is apparently one of mountain sage.

HONEY PROSPECTS.

THERE is not much to add to what we have already given on page 430 of our last issue, except to say this: Reports would indicate that clover has yielded tremendously in some large areas. Michigan is beginning to show some good reports. Illinois and Indiana continue to show that the season has not been very good. Reports from California are still unfavorable. Many letters show a lack of bees to gather the crop of clover where it is yielding well, and this fact will make a slight shortage in some localities.

A FREE BEE BOOK FOR TEXAS.

THE Texas Department of Agriculture has just issued a bulletin on bees, entitled "Texas Beekeeping," by Louis H. Scholl. It is, in fact, a complete text book on the subject, for it comprises 142 pages about the size of this. We presume that all Texas beekeepers can obtain a copy free of charge. Apply to the Commissioner of Agriculture, Austin, Texas.

As nearly as we can judge from a rapid scanning of the pages here and there, the matter seems to be carefully and well written, particularly with reference to the conditions as they exist in Texas. The book is well illustrated, many of the cuts having been taken from this journal.

SOWING AND REAPING; WAITING FORTY YEARS FOR A CROP.

SOME of the old gray-headed veterans will remember the time when we got short of barrels to contain our extracted honey, and your humble servant borrowed the wash-tubs of the neighbors; and when these were all full we borrowed the wash-boilers.

Wash-day came, and the good women came around wanting their utensils. But there was no place to put the honey. Mrs. Root asked, "Oh! won't those bees *ever* stop bringing in basswood honey?" It was about ten years after the war, and new "extracted" honey was selling in Cleveland as a novelty for 25 cents per pound. I finally told "Sue" that we would pump the water out of the cistern and scrub it up nice and clean, and fill it with honey. Well, under the stimulus of this great yield of basswood and clover I scraped up money enough to purchase a ten-acre lot in which I planted 4000 basswood trees; and we have waited patiently *over forty years* to see if another such harvest from clover and basswood would come, and now we have it. Pretty close to ten tons of honey, both comb and extracted, have been taken off during the past three or four weeks. (The two carloads of bees from Florida have "paid the freight," anyway.) Praise God, from whom all blessings "flow;" and if you too, my friend, have also been getting a great "flow" of honey, can't you say amen to the above?—A. I. R.

ABSCONDING SWARMS; TRAPPING THEM BY MEANS OF DECOY HIVES, OIL OF ANISE, ETC.

AFTER the article and picture on page 482 was in press I recalled that the matter was already touched on in the A B C and X Y Z of Bee Culture, at the close of "Swarming." An instance is there mentioned of a beekeeper in California who secured 17 swarms by having his empty hives stacked up near the apiary.

In regard to the oil of anise, some years ago a fellow in the South was getting a lot of money by "selling secrets" for capturing swarms. So far as I can recall, his secret was oil of anise to attract the runaway swarms. Referring to the article on page 482, the writer says he never saw a swarm of bees until that spring; and then he states, as I understand it, that he and his

brother secured 72 swarms by putting out 75 boxes. There must have been a terrible stampede of runaway swarms just then in that section.—A. I. R.

HAVE THE QUEEN-BREEDERS OF THE COUNTRY BEEN DEFYING THE LAWS IN REFERENCE TO MAILING QUEENS?

REFERRING to the recent ruling of the Postoffice Department (see page 492), that all queen-bees sent through the mails shall have a certificate from the State inspector showing a clean bill of health, Mr. J. F. Crowder, of Pasadena, Cal., has this to say in the *California Cultivator* of July 4:

Until the postal department came to our relief, the queen-breeders paid no heed to the laws of the various States, many of which had very good ones; but owing to the leniency of the mails they had never taken the trouble to look them up, nor to see whether they were carrying on a legal business. They had been defying the law of this State for eleven years, as the law was amended in 1901, and in the editor of GLEANINGS' own State for eight years. Shipments of full hives or colonies could be made in conformity with the laws, but shipments where made through the mails were difficult to regulate until the department came to the relief.

Italics ours. A little further on, Mr. Crowder quotes what he supposes to be a copy of the Ohio foul-brood law, which the queen-breeders, including ourselves, he says, "defied." This law was repealed two years ago. It had always been a dead letter, for the reason that it did not make a proper provision for the payment of the salary and expenses of an inspector; and even if it had been operative it made no requirement that queen-bees sent by mail should have a certificate, or a copy of one, from the State inspector. But just as soon as an effective foul-brood law was passed in Ohio (and we believe the beekeepers of the State will acknowledge we had as much to do in getting it passed as any one), our apiary or apiaries where queens were reared were regularly inspected and a certificate granted. But the new law does not require a copy of the certificate to be sent out with every package of queens sent by mail, neither did the old one. We were not aware of the provision in the California law. We, therefore, do not understand why Mr. Crowder should make the charge that the queen-breeders of the country have been "defying" the laws of his State and of Ohio. The word *defy* means a willful act. If they or we were ignorant of the special provision of the California law, Mr. Crowder is grossly ignorant of the provisions of the Ohio law. Before he makes the serious charge he does, he should make sure he is quoting from the right law. It has been published in GLEANINGS as it now stands, pages 171 and 306, for 1910, and has been sent broadcast over the State.

Section 1155-7 of the new law referring to queen-breeders reads:

SECTION 1155-7. It shall be the duty of any person in the State of Ohio, who is engaged in the rearing of queen-bees for sale, to use honey in the making of candy for use in mailing-cages which has been boiled for at least thirty minutes. Any such person engaged in the rearing of queen-bees shall have his queen-rearing apiary or apiaries inspected at least twice each summer season; and on the discovery of the existence of any disease which is infectious or contagious in its nature, and injurious to bees in their egg, larval, pupal, or adult stages, said person shall at once cease to ship queen-bees from such diseased apiary until the inspector of apiaries shall declare the said apiary free from all disease. Any person engaged in the rearing of queens who violates the provisions of this section shall, on conviction thereof, be fined not less than one hundred dollars nor more than two hundred dollars.

We have always complied with the spirit and letter of both the old law and the new one, and yet Mr. Crowder says in closing:

Mr. Queenbreeder, have you been living up to the laws of these two States? I for one say no. Get right.

We join hands with Mr. Crowder in the desire to protect the industry, not only in his State, but in every State in the Union; but we think he is a little rough in his implied references, especially when he quotes the wrong law, and one that was always a dead letter.

EDUCATING BEEKEEPERS WHO DO NOT TAKE BEE JOURNALS ALONG THE LINE OF FOUL BROOD AND FOUL-BROOD INSPECTION.

REALIZING that comparatively few beekeepers see the discussions on diseases of bees in the various bee journals, and at the same time appreciating the need of education, especially in case of slipshod beekeepers, Mr. Norman Gute, of Owosso, Michigan, has had published in a local paper a series of five articles on foul brood, the titles of which are as follows:

- 1.—Contagiousness of the disease; its spread over Michigan and the United States; its ravages to bees and honey crop.
- 2.—Symptoms of the disease, and how to detect it.
- 3.—Cause of infection; precautionary measures to prevent spreading.
- 4.—Foul-brood laws of Michigan.
- 5.—The cure of foul brood.

We regard this as a step in advance, for the old-fashioned beekeepers are unquestionably the ones who spread the disease through carelessness, and it is just this class that it is hard to reach through the channel of the ordinary bee journal. We think it would be well for beekeepers in other localities to adopt this plan, where disease is spreading rapidly. The material for the articles can be taken from the various text books if necessary, or some local well-known beeman can write the articles in an interesting way. Mr. Gute is himself

a newspaper man, and he would doubtless be glad to furnish copies of the papers containing these articles to anybody who might wish them, providing stamps were sent to cover postage.

A good deal rests upon the man who writes the article. Lengthy, technical discussions will not be read by the careless beekeepers, for they are uninteresting. The article should be short and to the point, and should be written in a wideawake, interesting manner.

TEXAS AS A HONEY STATE.

THE *Texas Magazine* for May, an illustrated monthly, contains an exceptionally interesting and valuable article by William Harper Dean, Assistant State Entomologist under Prof. William Newell, State Entomologist and Chief State Foul-brood Inspector of Texas. We should like to reproduce the whole article, but space will permit us to make only a few extracts here and there that will speak for themselves.

He gapes his astonishment to learn that there are more than a quarter of a million colonies of bees in the State, and that their annual honey production is estimated to run upward of 7500 tons. *

The value of bees can in no wise be computed by the amount of wealth they create through their production of honey and wax, for without bees there would be imperfect pollination of blooms, consequently poor crops of fruit, truck, staple crops—even failures. On the enormous alfalfa ranches of R. J. Smith, "The Alfalfa King" of Texas, you will find colonies of bees, for though Mr. Smith is not a beekeeper, by profession he knows well that the little workers will pollinate the alfalfa blooms, assuring a good crop of seed and a table supplied with the choicest of sweets. * * * *

TEXAS HAS BEES ON 38,000 FARMS.

Some 38,000 farms in Texas keep bees. Many of these, the majority in fact, keep but a few colonies to fertilize the cultivated bloom and to supply honey for home consumption. There are a great many beekeepers who are professionals, relying well nigh exclusively upon their colonies as a source of income. But professional beekeeping is not a common find. Those who rise to this point do so only by the closest observation, the most painstaking methods, and good business management, as will be readily understood when one takes the trouble to investigate the depth of complex life in these little socialistic communities. * * * *

The Goliad Bee and Honey Company, of Goliad, last year operated 1050 colonies of bees which produced 42,050 pounds of honey and 300 pounds of wax. At Beeville, Mr. W. H. Laws operated 1200 colonies which stored 21,000 pounds of honey. But Mr. Laws is not primarily a honey-producer. His primary occupation is the rearing of queen bees for supplying other apiarists. At La Pryor, Zavalla County, Mr. J. E. Chambers harvested 70,000 pounds of honey and 800 pounds of wax from 1000 colonies of the little freebooters. In the light of these few instances "waste" hardly seems a fit nickname for shaparral. * * * *

BEE FACTS.

Uvalde County alone has more than 15,000 colonies of bees.

Texas honey is rarely found on the Northern markets; it is practically all consumed in the State, though some shipments are made to Oklahoma and other close points.

It is not an uncommon occurrence in Texas to see a whole car of bees shipped to some locality where a new apiary is to be started, or where the beekeeper wishes to increase his honey output without waiting for natural increase in the bees on hand. * * * *

Both Central and East Texas reap a titanic honey harvest from principally cotton and horsemint, the latter a wild, generally distributed plant which furnishes nectar for a deliciously flavored product. Here the rainfall is quite heavy, and we find the honey darker in color than that of the chaparral sections. Located in Williamson County is one of the bee and honey kings of the State, T. P. Robinson. Though he operates a considerably less number of colonies than many of his brother "kings"—800 to be specific—he took from them last season nearly thirty tons of extracted honey. His output during a good average year is about 80,000 pounds. A "bumper" crop would raise this to the neighborhood of 100,000 pounds. This man is perhaps one of the wealthiest beekeepers in the country. During the last ten years he figures a total income of \$100,000. "And," says Mr. Robinson, "I have made this wealth by creating wealth, not by trading and scalping"—a philosophy which carries with it something lasting and good for a heritage. * * * *

CONDITIONS SAME IN TWO EXTREMES.

Uvalde County is one of the greatest honey-producing counties in the State, relying principally upon huajilla, catsclaw, and mesquite—chaparral growth in semi-arid latitude. As far west as El Paso County the beekeeping industry yields abundant returns. At Clint, El Paso County, W. J. Stahmann last year managed 800 colonies. They stored a total surplus crop, over and above their own needs, of 83,000 pounds of honey and 300 pounds of wax. * * * *

SOME OF THE FAILURES AND SUCCESSSES.

A novice in the art of beekeeping started out with thirty colonies of bees. At the end of his first season he took a surplus of 3000 pounds of honey and counted 110 colonies as the result of natural increase. This man gave his bees attention and kept them in modern frame hives.

One of the best-qualified beekeepers in Texas in discussing failure and success in this calling cited an instance in which a certain acquaintance of his farmed 200 acres. He loses money on cotton and pays all his expenses from the revenue of his bees. This man's custom is to work with his colonies two hours each day when he is "resting" from plowing.

In Waxahachie there lives a business man by the name of Mr. Tom Burlison. In 1910 he owned forty-one colonies of bees and kept them in the back yard of his home in the city. After business hours he found there was a world of relaxation and rest in attending to them. That year they averaged 100 pounds of honey and netted him exactly \$450.

Of course one must always take into consideration the fact that a poor season or a poor locality often means failure, but the man who studies his little corsairs and makes it his business to understand their habits and needs is better qualified to stand the attack of drouth and other setbacks than the man who puts his bees in a box hive and lets them stay untouched until he is ready to "rob" them.

IS A PROFITABLE SIDE LINE.

But if one has a reasonably good locality and season he should find it a profitable side line. Thousands do so, though it is a common thing to find a beekeeper who will tell you the venture does not pay in his particular locality and then in the very same section discover a man who will sign his name under the statement that beekeeping is profitable as a side line or a profession to the exclusion of other occupations.

For twenty-three years Mr. Z. S. Weaver has been a beekeeper. His home and apiaries are located at Courtney, Texas. During these years he has had two failures in the honey crop. For ten years his average production of surplus honey was 100 pounds extracted to the colony; for eleven years 75 pounds per colony. Mr. Weaver conducts a general merchandise business and says:

"I find that bees pay a better dividend than any investment I have ever made."

Mr. Weaver takes the best of care of his bees, and in return they do their very best for him.

The *Texas Magazine* is well illustrated and worth reading, especially by any one who contemplates going to Texas for a home. The price is \$1.50, published by the Texas Magazine Publishing Co., Houston, Texas.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

WHEN I READ, p. 375, that it remains to be seen how the fight for bee territory will be settled in California, I couldn't help thinking how much nicer it would be if pasturage for bees were owned the same as pasturage for cattle.

J. E. HAND has it about level as to swarm cells and supersedure cells, p. 267. Bees may start swarm cells, and then there's a let-up in the flow and they supersede; or they may start supersedure cells and a good flow comes on and they swarm. But they're the same cells in either case.

F. DUNDAS TODD writes that two years ago Henry Kacer, near the mouth of the Fraser River, B. C., took 400 pounds of honey from one colony, and netted \$72.00 for it! That would be \$7200 from 100 colonies. Looks like a scheme of that man Todd to cajole some of our best beekeepers across the line.

EDITOR HERROD, *British B. J.*, p. 53, advises beeway sections $4\frac{1}{4} \times 4\frac{1}{4} \times 1$ 15-16. Couldn't you concede that 1-16, Bro. Herrod, making the width $1\frac{1}{8}$, so as to keep company with your Yankee cousins? [Our British cousins use almost exclusively the sections referred to by Mr. Herrod. It is their standard. Why should they change their standard just to please their Yankee cousins?—Ed.]

WHITE CLOVER still keeps at its best, July 13, and colonies may yet average better than usual. Even so, there will not be half a crop, for the bees are lacking to gather it. [If the clover season is as backward about developing in your locality as it was here, you may yet secure a crop of clover. It yielded here nearly three weeks before it made much of a showing. Then all at once it began to pour in.—Ed.]

BEE-POISON is spoken of in GLEANINGS as formic acid; but Dr. Langer found that the poison was something separate and apart from formic acid, and latest research shows that formic acid is developed in honey by mere exposure to air. [This confirms the work of other investigators if we are correct. There has been altogether too much loose talk about formic acid in honey being derived from the bee-sting. We never had any patience with the old sting-trowel theory; and the older we grow the less inclined we feel to accept any theory unless it comes from a well-trained scientific man who is also a practical beekeeper. Some of

our bee literature of the past is ridiculous in the light of modern scientific investigation.—Ed.]

"IT IS QUITE an easy matter to have a lot of choice and vigorous queens reared by the time the swarming season begins," p. 380. I wonder if we could find out how generally that applies. How is it at Medina? In this locality I wouldn't give two cents apiece for queens reared thus early. [A good deal will depend on *when* the honey-flow comes on. It is possible to rear good queens before the honey-flow in Ohio, and, in fact, most of the Northern States. We venture to say that most of the Northern queen-breeders rear 25 per cent of their best queens before the main flow. You say you would not give two cents for early-reared queens. You possibly have in mind queens reared from cells built during chilly or cold weather, when the colony can not protect them properly. Such queens, if they live and lay, would not be worth much more than two cents; but in our locality we usually have conditions so we can raise the finest kind of queens, and have them laying before June 10 or 15, when our first flow comes on.—Ed.]

ACCORDING to figures given by Alex. As-tor, *L'Apiculteur*, 180, there are, in 1 lb. avoirdupois, 4536 young bees just born; 5040 field bees in April; 5465 field bees in May; 6043 robbers in time of dearth; 2926 gorged bees secreting wax. According to those two last items a bee may carry a trifle more than its own weight of honey. [Figures made by Profs. B. F. Koons, Lazenby, and Gillette do not altogether confirm those here given. They find that bees bringing in nectar run about 4000 to the pound, and empty bees a trifle over 5000. While the figures here given indicate that a bee *can* carry more than its own weight of honey, the figures made by Koons show that the most that a bee can carry would be half its own weight. On the other hand, we have seen a single bee carry away its own comrade; and if the honey-sac would distend enough it might carry its own weight of nectar. But while the bees can carry one of their own comrades in flight, it carries it only a short distance, and when it is fresh. But no bee could carry one of its own companions probably a mile or a mile and a half after having flown, we will say, a mile or more to get its load and then carry a weight equal to its own body.—Ed.]

NOTES FROM CANADA

J. L. BYER, Mt. Joy, Ont.

Drouth is very severe in many sections of Ontario at this writing, and the honey crop will be greatly cut down on that account. Personally we are more than satisfied with results up to date, as we really expected little if any honey at the apiaries here in York Co.

* * *

That picture on page 406, where 11 colonies of bees are shown with over 100 lbs. per colony piled on them, and gathered from milkweed, forces one to the conclusion that the plant must be a great secreter of nectar. There is very little at our home yards; but at the one yard recently moved north we have abundance. It is just opening, and it would be a pleasant surprise if it were even half as generous in yielding nectar as it is in friend Kirkpatrick's locality.

* * *

When sending copy for July 1, I stated that, by the time my next lot of stuff was sent, we would know if friend Crane's prophecy as to a good honey crop was correct or not. Although, as we have said in previous issues, clover was extremely scarce in our locality this year, yet what little we had yielded well from June 24 till July 7, then shut down at once, owing to drouth and the very small acreage which was rapidly ripening. Strong colonies stored a nice surplus; but many colonies in Ontario this year were not ready for the flow when it came. This fact is gleaned from a lot of correspondence with beekeepers of the Province. Nearly all the honey came in during the afternoons, and from 2 till 7 the flow would be heavy. At this date, July 13, basswood is not open. What little we have looks well, as trees are very full of buds. At both my east and north yard the trees are plentiful, and we are hoping that basswoods will be in good humor this year and give us a crop.

* * *

E. W. Peirce's arguments for cheaper honey are readable, and on the face of it appear *reasonable* too. Briefly capitulated, they sum up about like this: More bees to be kept, better management, and, as a result, more honey can be sold cheaper than at present. That is all right, friend Peirce; but why not apply the same argument to all other produce as well? Get other things cheaper, and then honey can be sold cheaper too. But with steak around 25 cts. per pound, and all other food values in about

the same proportion, it is a poor time to ask the beekeeper to take a less price for his honey, particularly when there is a ready sale for all he can produce; and it is not a question of what we will give you for your honey, but, rather, a statement on the part of the producer as to what he wants and expects to get for it. My honey is sold already, though it is all on the hives ripening; and, needless to say, I got what I asked, although I might say that my price is subject to the price that will be recommended by the crop committee of the Ontario association, which has not as yet had its annual meeting. This may show a little what a benefit such a committee is, when large buyers have confidence enough in them to be willing to buy honey in big lots subject to their ruling.

* * *

During this past two weeks the writer of these notes has been just about busy running back and forth from one yard to another, trying to keep things in shape and to avoid losing any swarms. We have had very little swarming; and what we had was mostly caused by superseding queens, and in this respect old failing queens during the honey-flow are a great nuisance, as you hardly know how to treat a colony that is preparing to supersede their queen; that is, when the colony is at an outapiary and no one in charge. However, I had only one swarm to skip out, and that happened day before yesterday. The next day I was at the yard, and young queens were piping in great shape. I opened the broodnest and cut out about a dozen ripe cells, one queen being noticed as leaving the cell when I lifted out a comb. She ran down in the hive; and I thought that, after shaking all bees off combs and destroying every cell, no second swarming would take place—particularly so, as little honey was coming in. I closed the hive, and in less than ten minutes they swarmed, the swarm alighting in two clusters about 50 feet apart. As the old queen had been a good one, the two small swarms were hived for the sake of the young queens. They certainly had the swarming fever in bad shape, and I suppose that, when I went through the hive, a number of young queens hatched when the bees' attention was called away from guarding the cells; and with three or four virgins loose in the hive, it was a case of swarm at once or else give up the notion and let the queens fight it out.

BEEKEEPING IN CALIFORNIA

P. C. CHADWICK, Redlands, Cal.

There has, perhaps, never been a season in California that showed such spotted results, even in reach of the orange belt, where the bulk of the season's supply was secured. This is due very largely to the failure of the filaree to mature early enough to aid spring breeding, owing to the extreme dryness of the season up to March 1. A few apiaries in reach of filaree in irrigated sections, or where willow or other plants were available for an early supply of pollen, built up rapidly with good results. This only proves what I have previously said, that bees travel a much greater distance when there is some special attraction that excites the entire flight in one direction than they will where there is nothing more than pollen or a hard-earned load of nectar to be secured.

* * *

The following records begin on April 26, and were discontinued on May 2, owing to unfavorable weather and little progress being made by the bees. On May 13 the scales were moved to another colony, and records carefully kept until May 28. The object in this record was not so much to ascertain what the daily increase was as to test some theories of my own as well as those of others, though the former was a factor. The keeping of this daily record has in some respects been a revelation to me, and has disproven some ideas I had held almost as law, and decidedly upset some theories of others. I had always held to the idea that the orange yields most on moderately warm days—that is to say, those days when bees could fly freely, but when there was a lack of intense heat and direct sunshine. To my surprise the best record of any day was made with the temperature running up to 96 degrees at 2 P.M. The most ideal day, according to my previous notions, the temperature was about 75 degrees. The bees tumbled all over themselves in alighting, there being a constant stream crawling up the alighting-board where they missed the entrance; but the record this day was three pounds short of high-record day. So I learned that, when bees come in apparently over-laden with nectar, they are in reality no heavier laden than when the weather is sufficiently warm to enable them to alight promptly, but are retarded in flight by being more or less benumbed by cold nectar and air. The amount stored after 12:30 P.M. was double that of the forenoon, no matter how favor-

able the weather. The highest record of any day was 11½ lbs. Only 4 lbs. had been gathered up to 12:30 P.M. Another observation was that the heaviest gain was during the last 1½ hours of the day; also that, during the first two hours of very favorable days, the shrinkage was often greater than the increase from the field. Arthur C. Miller says that the evaporation is greater up to 2 A.M. than during the remainder of the night. I find differently, in fact, under my observation the evaporation was continuous and nearly equal at all times, continuing until far in the forenoon on foggy mornings. The early morning flight to the field causes a noticeable decrease in weight, while at the day's end, with the retiring of the workers, it adds decidedly. On one cool cloudy day, when there was what seemed to be a fair flight, the evaporation of the previous day's heavy gain was actually four ounces more than was gathered all that day. My conclusion was that the evaporation is continuous until the final sealing of the cells.

I give below the weights taken during five successive days, with weather conditions for each day:

May 22, at daylight, weight 147 lbs.

May 22, at dusk, weight 155¼ lbs.

Gain for the day, 8¼ lbs.; partially cloudy, with cool west wind.

Daylight, May 23, 153¾ lbs.—a shrinkage of 1½ lbs. for the night.

Afternoon, May 23, weight 164½ lbs.—gain for the day, 10¾ lbs.; fine day.

May 24, daylight, 162½; shrinkage for night, 2 lbs.

At dusk, 173½ lbs.; day's gain, 11 lbs.; fine day.

May 25, daylight, 171¼ lbs.; shrinkage, 2¼ lbs. At 12:30 P.M., 170 lbs., showing a loss of 1¼ lbs. for morning. Dusk, 171 lbs.; loss for day ¼ lb.; cloudy, dull, cool, with fair flight during mid-day.

May 26, dawn, 169 lbs.; loss for night, 2 lbs.

Note that the loss for the previous day was ¼ lb., and previous night 2¼ lbs., or a total loss of 4½ lbs. for 48 hours. Though the flight on the 25th seemed to be fair, the weight did not come with it, indicating that the workers, after a short time in the field, returned more to warm up than because of being honey-laden.

Dusk, May 26, weight 177 lbs.—a gain for the day of 8 lbs.; cloudy, clear afternoon, with heavy flight forenoon.

Beekkeeping Among the Rockies

WESLEY FOSTER, Boulder, Colo.

Just to show the variations and the different kinds of climate in the one State of Colorado, and the difficulty of getting an early crop report, consider that comb-honey supers have been put on hives and filled during October. This is done frequently in Montezuma Co. I have seen supers filled in May at Boulder. There is a variation of six months for the one State. Supers are not often taken off until August in Montezuma Co., and more came off in September than in August.

* * *

The premium list for the Kansas State fair is out, and includes \$200 in premiums for bees and honey. The premiums for honey-producing plants is the only class that is limited to Kansas exhibitors. Mr. J. P. Lucas, of Topeka, is superintendent of the bee and honey department, and is making an effort to have a good showing. If you are interested, write to Mr. Lucas and he will see that you get a premium list; and if you care to exhibit he will gladly welcome you.

* * *

THE SEASON SO FAR.

Frequent rains and abundant supplies of water for irrigation have made a fine showing on the alfalfa and sweet clover. The first cutting of alfalfa has made as high as three tons to the acre in the best fields. Rush of farm work has delayed many in cutting alfalfa, and the bees have had a chance. Sweet clover is now in bloom; and with a continuance of the showers we shall get honey between the bloomings of the first and second growth of the alfalfa. Every wild flower yields honey this year; and the way the bees were swarming the first of July would lead one to remark that swarming sometimes is a problem in Colorado. Horsemint always yields abundantly when rains are copious, and the bees give their whereabouts away when working on the horsemint by coming in with the silver-colored pollen dusted over their backs. Colorado should make a good start at retrieving her winter losses this season, and we hope that a honey crop will be also forthcoming. To-day, July 7, the bees are entering the supers in a generous way, and a few finished sections have been taken off.

* * *

The Grand Junction fruitmen are adopting the layer pack, and have opened schools to teach the packers how to pack their fruit. This shows the trend of the grad-

ing problem. The apples will be counted, and the number stamped on the outside of the box. The Northwest is now grading apples for color, size, and shape; and the adoption of this new method by the Colorado fruitmen will mean practically the same thing. Here is a clipping from one of the dailies, The *Denver Post*, regarding the new move.

GROWERS ADOPT LAYER APPLE PACK; EACH BOX TO CONTAIN A CERTAIN NUMBER MARKED ON THE OUTSIDE.

The layer pack for apples has been adopted by the Grand Junction Fruit-growers' Association, and schools of instruction are being held at different points of Grand Valley, where the growers are shown the advantages.

By means of this new pack it is expected practically to revolutionize the fruit industry in this State. The chief advantage in the new standard, which will eventually be adopted all over the State, is the fact that the apples are layered and counted. Each box will contain a certain number of apples, which will be marked plainly on the outside. The purchaser, therefore, will be able, whether he is dealer or consumer, to ascertain just what he is buying when securing a box of Grand Valley apples.

Demonstrations of the new pack are being given daily by the inspectors of the association. The young women who do most of the packing will be given exact instruction as to how each apple must be placed in the box.

* * *

BEE-INSPECTION

Dr. Phillips says that it looked to him as though the two bee-inspection laws of Colorado were both in force. This was my opinion at first; but the intention of the legislature was doubtless to repeal the old law, and I think it is repealed by the new one. This does not hinder the county commissioners from paying the salary of a deputy county inspector, but takes the appointment out of the hands of the county judge. The beemen can reach the commissioner easier than the judge, and the commissioners feel better to have the say as to whom they will pay for doing the inspection. If the beemen take interest enough they can and do tell the commissioners whom they want for county deputy inspector, and the office of State entomologist has been able to co-operate with the selections made by the beemen and commissioners, and has commissioned them as deputies of the State entomologist, to whom they report, and under whose general direction they work. We want some changes in the law, but are getting some results as it is.

From reports already received, the percentage of foul brood has been materially reduced over last year's percentage in the counties of Mesa, Delta, Montrose, and Fremont. Other counties are to be heard from, and it is hoped that the reports will be equally good.

Conversations with Doolittle

At Borodino, New York

DRONES OUT OF SEASON.

Please give me a practical way of raising drones during a dearth of nectar. Then also tell how to care for them so the bees will not drive them out.

Nashville, Tenn.

W. F. MORRIS.

The first question is a hard one. When there comes such a dearth of nectar that all the drones are killed, especially if it comes at the close of the white-honey harvest, it is almost impossible to make any colony start to rearing drones again in this locality. The bees seem to know that no more drones are necessary for the remainder of the year, and, no matter how regularly or liberally we feed, the queen will not deposit eggs in drone comb, even if we make half the cells of the combs of that size. But, strange to say, should there come a yield of nectar from buckwheat three or four weeks later, the queen will lay in the drone-cells, as we often have swarms issue when there is a two or three weeks' yield from that source. But, as I said, we may feed as much as we please during the period when the buckwheat should secrete nectar, and it seems to have no effect on drone-rearing, even though the amount stored may be twice as great as though the honey were stored from buckwheat.

In some cases where the bees were bent on superseding their queen I have succeeded in having a few eggs laid in drone-cells by feeding in a time of dearth. The older the queen, the more drones will be reared; therefore if we try for drones out of season we must use old queens or those on the point of failing, even though young in years.

If there is a drone mother at an out-apiary, or one is taken with her colony three or four miles from home a week or two prior to the close of the main nectar flow, her drones may be made useful in the home apiary in this way: Take the bee-funnel and a box having queen-excluding metal on one side of it to this colony as soon as the flow from nectar ceases. Then look over the frames till the comb is found that the queen is on. Set this aside, and shake all the other frames in the funnel, so that the bees will "rattle" down through it into the box below. The combs do not have to be shaken very hard to dislodge drones, for they do not stick as tenaciously as do the workers. If there are many drones on the comb with the queen she can now be picked off and placed on one of the combs, when these can also be shaken down through the

funnel into the box. Now close the funnel hole in the box and place it near the entrance to the hive, having the queen-excluding metal so that the workers can run out near the entrance and into it, while you are getting the hive properly closed. A few workers should be left in the box to care for the drones on the way home; and when the right number remain, close the queen-excluder side with wire cloth.

Arriving home, take the box of drones to the prepared queenless colony; open the funnel hole of the box, turning that side of the box down over the frames, when the drones will run out into the queenless colony, where they will be at home till they are used for mating purposes or die of old age.

In order to have drones clear to the close of the queen-rearing season, I prefer the following: A day or two before the nectar flow has entirely ceased I go to the colonies having my best drone mothers, which were prepared for drone production at the opening of the season by giving two or more frames of drone comb, and take out these drone combs, substituting frames of worker comb. These will have more or less drone brood in them, from the egg to the maturing brood, if we do not wait till the flow ceases, and they should be set in the prepared queenless colony. In this way we gain from 24 to 28 days, having young vigorous drones all the way through. This colony having these drones and the drone brood must be kept *queenless* all the time after we select it for keeping drones; for with the great number of drones it will contain in proportion to the workers, the drones would be slaughtered on the least provocation when there is a dearth of nectar. I used to allow such a colony to rear and fertilize a queen; and as soon as she got to laying I took her out and gave another ripe cell; but as the season waned the bees would go to persecuting the drones as soon as the queen became fertile, even before she had laid an egg. Frames of sealed worker brood must be given this colony every two weeks to keep up sufficient force to care for the drones, and regular feeding resorted to, so that there will be a vigorous flight every fine day. If a two or three story hive is used, better results will be obtained, especially if the third story is filled with frames of sealed honey. A large colony *rich in stores*, and a daily "ration," will always give a vigorous flight at any time the queens can go out.

General Correspondence

AN EFFICIENT COMB-MELTER

Something to Sterilize the Honey as well as the Wax of Foul-broody Combs

BY WESLEY FOSTER.

Mr. R. W. Ensley, of Read, Colorado, operates about 700 colonies of bees in a district where foul brood is prevalent. In building up his apiaries he has bought many hives from his neighbors, and, as a result, has many old combs and diseased

FIG. 1.—Back view of Ensley's comb-melter.

ones to melt up. One or two hundred hives of comb is not an unusual amount to be rendered during the year. Mr. Ensley designed and had built for him a comb-melter to render the honey and wax from these old combs. He wanted an apparatus that would separate the honey from the wax and leave both in good condition.

First he has a double boiler set over his furnace; then above this is the comb-melter proper, which is nothing more nor less than an alternating series of steam-chambers and comb-receiving chambers. The comb-chambers are about $2\frac{1}{2}$ inches high, 20 inches wide, and 30 or more long. Each comb-chamber will take three Hoffman frames at a time, and there are six in all. More can be added if wanted, by building the melter higher. The comb-chambers slope toward the back, the lower end of each being open so that the honey and wax can run off into the double boiler below. A piece of coarse screen wire across the lower end of each comb-chamber keeps the coarsest of the refuse from getting into the boiler. This refuse is raked out and run

through the wax-press. The fronts of the comb-chambers are closed with wooden drawers fitted with wire handles, and beveled so they will slip out easily.

The steam-chambers are all connected with live steam from the double boiler below by means of the pipe shown in the illustration. The steam passes into the lower steam-chamber (below the first comb-chamber), and on the opposite side is led out and up into the next higher space for steam, which is just below the second comb-chamber. The steam is led back and forth and up till the top is reached, where there is a hole by which the exhaust steam escapes. There is some condensation in each steam-chamber, and a small hole is made in the lower corner where this water can run out. Fig. 2 shows that these holes are all in line, and the water drips down upon a tray, and a trough leads back into a funnel feeding this water back into the double boiler. The condensation is not enough to keep up the water-level in the boiler, so a pail is placed on this tray, with a small hole in it, feeding water into the boiler as fast as needed. To prevent the steam from escaping from this hole a small cloth is placed into it, the water soaking through, but the steam does not come out. Of course, there would be trouble if the pressure were great; but heavy pressure is not necessary with an apparatus of this kind. The small boxes on the side of the melter are to carry the steam from one steam-chamber up past the comb-chamber to the next steam-chamber above.

FIG. 2.—Front view, showing the doors to the comb-trays.

A tray is attached below the comb-chamber doors to catch the refuse when removing frames and raking out the chambers. The double boiler is tipped slightly forward and to the side upon which the faucet is

FIG. 3.—A, wax-compartment; B, first honey-compartment; C, second honey-compartment; D, honey-exit; E, honey-exit, opening into second part; F, honey-exit, opening into first part; G, wax-exit.

placed, facilitating the draining of the honey and wax. The comb-melter resting upon it slopes straight back level from side to side. I did not measure the drop, but I should judge that it is about three inches.

From the double boiler the honey and wax are drained off into a galvanized-iron wax and honey separator illustrated in Fig. 3. Mr. Ensley tells me that this honey and wax separator works well, but that the sides should be made sloping so that the wax cakes forming when the flow is stopped will be easily removed. The cost of this whole outfit was about thirty dollars. It was the first one he made, and he had to pay the tinner for the time they worked, and for the changes that were made that had not been counted upon. Another machine would not cost as much as this one.

The steam-chambers were first made, and the comb-chambers were formed by soldering on tin strips about three inches wide on the sides. The back was then closed with tin, and the front with the doors, etc.

Boulder, Col.

[We understand that the object of this melter is to save the honey. If the combs were in shape so that they could be run through a honey-extractor first, it is probable that a good wax-press would save time and would cost less besides. But the outfit here shown would sterilize the honey in the first place.—Ed.]

WOULD THE NATIONAL ASSOCIATION BE OF BENEFIT TO BEEKEEPERS OF CALIFORNIA?

BY P. C. CHADWICK.

On page 154 of the April issue of *The Beekeepers' Review* Editor Tyrrell takes a shot at our State Association. From the trend of his remarks Mr. Tyrrell seems to think the California Association is out after blood, and tells how he is receiving individual memberships that are being placed in other National branches outside of our State, and also how the National, if they can not get the support of local associations, will go calmly to work and organize their National members in that State.

It is a pretty easy matter to sit at a desk in Detroit and tell how all this work is going to be done; but doing it is another proposition; and if calmness prevails long I fear the editor's work would not progress very rapidly.

We have no fight on the National; and whenever it is shown that we can receive more for our money there than from our State Association we will surely be there. Personally I love the "Old National," and have no crow to pick with it; but I do not consider this talk about what big things the National is going to do as idle, from the simple fact that it is the consensus of opinion here that we have never received benefit commensurate with what we have paid in.

The men at the head of our State association have their work at heart, and have paid expenses from their own pockets, running into the hundreds, to get the beekeepers together in this State, and they are going to succeed so far as the progressive element of the State is concerned. My advice to the National is to keep hands off. When we get thoroughly organized, if the National can prove to us additional benefits we will not hesitate to come in; but threats will only make the breach wider and our return more impossible.

Redlands, Cal.

[We could not feel that Editor Tyrrell meant to cast any reflection on the beekeepers of California, and we therefore offered him the opportunity of replying to the foregoing, which opportunity he accepted, as shown by the following:—]

Brother Chadwick, I wish I could answer your article by drawing my chair right up alongside yours and talking this matter over instead of putting it down in cold type. Somehow or other it is hard to get things in print just as I mean them.

If any thing I have said gives the impression that I am in any way against the

California Association, I want to say that I am sorry, for that is not the feeling I have. Far from that, I realize that every help should be given these different associations, and I realize the fact that they are doing a good work.

But you must not forget that I am serving the National Association; and as such servant I must advance its interests and that of its members wherever possible. Proper organization means a branch in every State; and if a State association said, "We won't join the National," you would hardly expect me to lie down and say, "It's no use trying to do a thing in that State." We must protect our members there the same as you do yours.

You are right in believing it is easier to sit at a desk in Detroit and tell how this work of organization is to be done than it is to do it. My twelve years' work along organization lines, from a local solicitor to general field manager for a farmers' organization now numbering 70,000, proves this. But, friend Chadwick, it can be done; and the fact that many think it can not makes the work that much more interesting.

After all, I believe we are together in our desires, even should we differ in the methods. Both you and I would like to see your State association prosper. Both of us would like to see the National prosper. And I believe we both agree that, if the California State and National could be pulling together in double harness, neither taking from the other but rather adding to, a great deal more good would come of it than for either or both to travel alone. Then why can't they?

Detroit, Mich.

E. B. TYRRELL.

BULK-COMB-HONEY-PRODUCTION POSSIBLE FOR NORTHERN BEEKEEPERS

BY J. J. WILDER

I have enough tangling and knotty problems to solve in beekeeping in my own part of the country without soaring away to the North, and there trying to help the beekeepers over their rough places; but allow me to offer a few suggestions that might make bulk-comb-honey production possible in the North as well as here.

The greatest fear seems to be that honey thus packed would soon granulate, or candy, and that there would be no demand for it in this condition. This would certainly be the case, for it is true that in the South we have no market for such an article, and perhaps never shall have. Such honey must keep in a liquid state until it is sold and

consumed — that is, the extracted honey which is poured in around the comb honey to fill the package and make it uniform in weight. Now, if this extracted honey would retain its liquid state the chunks of comb honey packed in it would not granulate or candy; and all the contents of the package would remain liquid and transparent. It would be, in fact, a very attractive package, bringing the highest possible price in any honey market.

Now, it would take a fancy article of extracted honey (and of a good mild flavor too) to pack up the light comb honey of the North as bulk comb honey, else it would spoil it; and I am not familiar enough with the honeys of the North to know whether there is such an article of extracted honey produced there that would not candy or granulate. If not, this would be another great obstacle in the way; but this could be averted by obtaining it from other beekeepers in other sections of the United States. It could be bought at the prevailing prices of extracted honey, transportation charges paid, and packed with comb honey would bring on the market the prevailing prices of comb honey, which would net the buyer a good profit after these expenses. If it were desired to pack up an off grade of comb honey into bulk comb honey in cans and pails, an off grade of suitable extracted honey could be obtained for this purpose.

The question might be asked, "Could a sufficient amount of suitable extracted honey be obtained for this purpose?"

I will answer yes. If the comb honey is packed properly in the proper size of jars it would not take much extracted honey to pack up a lot of comb honey. I have tried all sizes and kinds of vessels for packing bulk comb honey in for a number of years; and I have found the pint or 24-oz. Mason fruit-jars of the flint variety the best all-around package for packing up fancy honey in this manner. These jars are just as high as a comb of honey cut from a regular shallow extracting-frame is wide; and all that is necessary is to cut it across the proper width, which should be nearly as wide as the mouth of the jar; and when two of the pieces thus cut are placed in properly there is not much room for the extracted honey, and therefore a small amount of honey would go a long way. And it could be packed in cans and pails of a suitable height, in a similar manner.

But coming closer to the supply of suitable extracted honey, and how to obtain it, in our great Southeast there are many beekeepers located in the tupelo-gum regions who make a specialty of producing extract-

ed honey from this plant, and carloads of it are put on the market each season packed mostly in 30-gallon barrels. This honey is in every particular suitable for the purpose, and the bulk-comb-honey producer of the North could get in touch with the producers of this honey, and contract with them for so many barrels each season to pack up their honey in. There is no question about this honey being suitable for the purpose, for I have been using it for a number of years with perfect satisfaction. Our honey from the cotton plant is quick to granulate if extracted, and will gradually do so in the comb as cold weather comes on; but if it is packed in tupelo honey it will not. I have a jar of it which I have had packed for several seasons, and it has been in my refrigerator now for several weeks, and it shows no signs of granulation, but remains clear and transparent. I don't know whether the test is severe enough; but I believe it will stand any climate almost indefinitely and not granulate. No doubt beekeepers in other sections of the United States produce a similar article that would be equally satisfactory, which could be obtained for the same purpose and in the same manner.

Cordele, Ga.

To be continued.

MUTABILITY OF THE DOMESTICATED BEE

Parthenogenesis Should Prove Helpful

BY LEO ELLIS GATELEY

I was asked recently if, during the past half-century in which we have been importing Italian bees, any thing has been gained above the regular strain. Replying to that, I beg to say that, in respect to the *possibilities* of breeding, a great deal has been gained. While the yellow bees of this country in general fall below the average compared to the darker bee it is, without any doubt, the result of faulty breeding. The original strain has for many years been kept in large apiaries devoted to honey production, and bred accordingly. Extra-yellow bees have been confined to less extensive apiaries devoted to queen-rearing, and selection in breeding made for color alone. By taking this bee as it is, and improving it along general lines, it would soon equal the strain from which it originated. The important fact, however, in regard to the goldens is that it marks clearly an epoch in bee improvement, and illus-

trates the mutableness of the species. In condemning this strain for points upon which it has not been bred, beekeepers apparently fail to realize that, while the older countries from which the bee was introduced into America are still content to keep the same old varieties of that period, we have developed a new and distinct type. It is a deplorable fact, that just how the development of this American product was begun and carried out is not on record, but was doubtless accomplished through a long course of selecting highly colored mutations for breeding stock. The modesty and simplicity of American queen-breeders is exemplified, also, by the fact that this product of unrecorded thought and painstaking is a nameless quantity, satisfied to appear under such impressive titles as "Golden," "Beauties," "Nutmeg," "Five-banders," and "Golden-all-over." Nevertheless, the development of this distinctive strain but emphasizes the mutability of the Italian bee, of which there has never existed reasonable grounds for doubt.

In the opinion of some, the parthenogenetic development of drones will prove an obstacle to progress in breeding for improvement. Parthenogenesis should be incalculably helpful in so much that relief is here found from having to see that all drone-producing queens are purely mated. Were it not for parthenogenesis the task of breeding would be indeed complicated; for if any of our young queens should prove to be mated it would work havoc with our breeding operations. Let us be thankful, then, that we have this invaluable aid, found absent in the breeding of other live stock. Though the mating of queens has many difficult points, one can, in the average locality, control the flight of drones to an extent that, for all practical purposes, there will be no haphazard mating.

Unquestionably the one real bar to progress is in making intelligent selection of breeding queens. The few who take adequate interest in breeding bees fail to realize the necessity of seeking improvement along general lines; and colonies are so deceptive at honey-storing that only by possessing a clear understanding of how outside conditions affect the amount of surplus gathered can one make judicious choice. The colony storing the least yield may, under certain circumstances, be the one most desirable when breeding for honey; and that producing the enormous yield, if it is not a black or hybrid one, may result in any thing but a mutation in the sense expected.

Ft. Smith, Ark.

F. B. Cavanagh's two-cylinder Jackson automobile, with the carrying rack at one side, the latter being tipped over so as to give a top view.

CONSTRUCTION OF THE AUTOMOBILE TRAILER

BY F. B. CAVANAGH.

In response to inquiries regarding my auto and its different sets of "harness" I wish to give the following description:

Fig. 1 shows the machine with a top view of the carrying rack, which was placed on its side at the rear. The back fenders must be removed for use with either trailer or rack, both being built out over the rear wheels. The projecting side-boards of the rack also extend forward and form extra seats when we have a five-passenger load. This rack could be improved by making it about 18 inches longer, and building wide double doors in place of the narrow door which, as shown in the photo, is propped up with a stick.

This picture is shown for the purpose of making clear to the reader the means of connecting the trailer to the auto. This connection must, of course, be very flexible, both laterally and longitudinally, otherwise difficulties would arise when driving on uneven ground.

The drawbar, or "fifth wheel," if we may call it that, for lack of a better name, is built on a 2x6 secured with four bolts which extend through the frame of the automobile, and which are easily removable. In the middle of this piece is a one-inch piece with a V-shaped slot cut out and covered with a solid plate of steel $\frac{3}{8}$ inch thick. This plate draws the trailer with the $\frac{3}{4}$ inch steel bolt which is shown in Fig. 2, and extends in order through the crosspiece of the

trailer, the steel plate, the reach of the trailer, and finally the automobile deck, where it is secured with a $\frac{3}{8}$ bolt and nut.

The hole is made large in the deck of the auto and in the 2x6, to allow flexibility in all directions. It will be observed that the pulling tension is all on the steel plate with the auto and with the trailer jointly, from the reach and the $\frac{3}{4}$ -inch machine-steel kingbolt. Lateral stability is secured by contact with an upper plate on the cross-piece of the trailer, corresponding in size to the lower one. These parts must be made of the best material, and must be strongly built.

Fig. 2 shows the trailer reared up to give the reader a general idea of the construction. Two strong carriage wheels and springs of suitable weight are required. The reach extends upward at an angle to within a foot of the connection to which it enters on a parallel with both trailer and auto decks. The 2x4's supporting the deck are about 11½ ft. long, and crosspieces are 1¼x5x6½ ft. long, and of white pine. The deck is tongued and grooved, $\frac{5}{8}$ inch yellow pine. A strip of $\frac{3}{4}$ x4 pine is nailed to the edge, forming a 1½-inch ledge when used for hauling. The iron loops around the edge hold the cover, which is used in hauling bees and to hold the wire-cloth canvas trailer top.

Those who have seen the picture on page 500, Aug. 15, 1911, showing the trailer with a load of supers, will understand how the top is connected to the two-foot wire-screen framework. A canvas cover with ample windows on each side is secured by strips

Cavanagh's automobile trailer. View from under side.

nailed all around the upper edge of the screen framework. A light frame with gable top is hinged at each end to the screen frame so as to swing toward the center when the top is collapsed for traveling. When extracting, the ends are held upright with removable braces at each corner, and the cover stretched in position. It will be observed that, if the ends were hinged directly to the trailer deck, instead of to a two-foot stationary frame, there would not be room for the top to be folded down flat on the machinery.

Hebron, Ind.

SELLING HONEY DIRECT TO THE CONSUMER

Should the Selling Price be Increased to Meet the Growing Demand?

BY HARRY LATHROP

In an editorial, page 35, Jan. 15, I note the following: "But the scarcity of comb honey and its higher price should make producers wake up to the importance of

producing more section honey." Present conditions would not seem to justify me in changing from the production of extracted to that of comb honey. My extracted honey nets me 10 cents, and is sold at that price direct to consumers, or to merchants or distributors. I am unable to secure more stock, even at 9 cents cents in job lots delivered here; and having sold out I must tell my customers that I am unable to fill orders before the new crop comes in. I have a letter from President York in which he advises me that some lots of fine comb honey are being sold in Chicago at 12½ to 13 cents. Those prices do not look good to me in view of the fact that I can not buy western white extracted honey in that city at less than 9 or 9½ cents. We ought to work toward uniformity of price and a stable market for our product. I advocate

selling direct to consumers, and at as low a price, or as near first cost, as possible. This will increase the consumption of honey, and make it a popular food, as it deserves to be.

I will explain why I ask jobbers or merchants one dollar a pail for a ten-pound package, the same as the one who buys only one pail. If a customer comes to me for a single pail of honey I hand it to him and take his dollar. I have no boxing to do, no shipping, and many times do not even put a label on it. He gets the honey at a wholesale price by coming after it. If a customer writes for a single pail by express he incloses one dollar. The express charges on the honey will be 35 cents. This leaves a margin for the distributor or merchant who will buy by the dozen and have the honey shipped by freight. When I am asked to make a lower price on lots I tell the purchaser to make his own selling price and get his profit out of the consumer, and not out of me. There may be some weak points in this method, but I can't see where it is unfair to any one. True, it gives my home

customers the advantage of a minimum price, and that is what I want. I wish to sell as much around home as I possibly can. If I could sell it all at home I would not ship any to help glut distant markets. My honey nets 10 cents, as the pail is weighed in.

I made only one mistake in my management, as I see it, the past season. I sold 3000 lbs. of amber fall extracted to a cracker-factory at 7 cents on cars at my station, and lost the cans in which it was stored. I reserved a thousand pounds of the same honey, and sold it out the same as the white at ten cents net. I find quite a number of customers who prefer this amber honey straight. Others think that a blend of half white and half amber is just right. This latter is, indeed, a very pleasing honey, and I believe we have no need to take a greatly reduced price for a good quality of amber honey from heartsease and the general autumn flowers of the middle States.

I think it is a good thing to discuss prices and to let each other know what we are doing. I have reached a point where I must either keep more bees and produce more honey to supply my growing trade or raise my price in order to cut some of it off. I can't buy honey at a price that would allow

me to make any thing for the trouble of re-packing and selling—at least not this season. I know that farmers would raise the price of eggs to one dollar a dozen if there was a scarcity and they could get that much; but I don't feel like raising the price of honey in that way, nor do I believe it would be good policy. Tell me, if you can, editors or readers, what would be the best thing to do.

Bridgeport, Wis., Feb. 7.

DINE'S METHOD OF RAISING QUEENS

Where the Scheme Originated

BY I. HOPKINS.

Under the above heading there appeared in the *Canadian Bee Journal* for March last, page 75, an article by Mr. Oscar Dines, on the plan he has adopted for raising queen-cells, and also an editorial introduction to the article, in which it is claimed that Mr. Dines is the originator of the method. The plan is also described by Mr. Holtermann in *GLEANINGS* for March 15, page 177, Mr. Dines' experience being given as set out by himself.

FIG. 1.—Portion of comb prepared for cell-building in New Zealand.

Now, it is not often that American editors are caught napping; but I think I can prove that they do indulge in a nap sometimes, and that Editor Hurley, of the *Canadian Bee Journal*, must have been sleeping soundly when he wrote that editorial or he would certainly have known where the scheme really had its origin, which was neither in America nor Canada. SCHEME FIRST ADOPTED IN NEW ZEALAND

AMONG ENGLISH-SPEAKING PEOPLE.

Although not the originator, I believe I was the first to adopt the method among English-speaking beekeepers. During the season of 1909 I made my first attempt at one of our state apiaries, which resulted in 60 fine cells, and on the second venture 80 grand ones were obtained. I took photos of both combs (one of each of which I am sending you); but as they were taken in a very bad light, inside, to avoid draft, they are not very clear. Being a staunch advocate of the Alley plan of raising queens, the method appealed to me, and we still carry it out in the government apiary.

On October 23, 1909, I wrote Dr. E. F. Phillips, giving him a brief description of the method, telling him where I got it, and sent him a photo of the first batch of cells. He afterward informed me that he had explained the system before, I think, the New

York convention of beekeepers. In the August number of the *New Zealand Farmer* for 1910 (which you, Mr. Editor, may have in your files) I published the process in full, with illustrations; and when revising for the fifth edition of my "Australian Bee Manual" in June, 1910, I included it, so that the method, though apparently having failed to reach the majority of beekeepers in America, has been well ventilated in this part of the world for over two years and a half.

Possibly Dr. Phillips may have forestalled me in this matter; but as I am ignorant whether he has or not, I can not be blamed for repetition if he has. I hope Editor Hurley will not get too great a shock when I tell him that it was out of his own journal for July, 1909, page 255, I got the information, contributed, I think, by Jacob Habera, or Habbera, and translated from an Austrian bee journal. This, I think, will clear up the mystery.

THE PRACTICAL USEFULNESS OF THE METHOD

You, Mr. Editor (page 178, March 15), express a doubt about its being wise to allow more than two dozen cells to be attended to in one colony. That was about the number I considered enough at one time; but more mature experience has convinced me that a strong two or three story

FIG. 2.—Sixty good cells obtained on this comb at the first attempt. First week in October, 1909.

FIG. 3.—Eighty good cells—second attempt, second week in October, 1909.

colony, overflowing with bees, with many thousands of nurse bees, and plenty emerging every day, deprived of all unsealed brood, can readily attend to and bring to maturity more than twice that number (as I have abundantly proved) of first-class queen-cells. All our cells at the government apiaries are raised in such colonies. I never did believe in the "swarm-box" and small-colony system of raising queen-cells.

Mr. Dines describes his plan of supporting the frame of comb in a horizontal position, the trouble connected with which seems to me unnecessary. All we do is to lay an empty frame on its flat, over the lower frames; place the frame of comb on this; cover the latter with a light mat; put on an empty half-story, and the top box or boxes above it. In four or five days we return the queen to the brood-chamber; place on a queen-excluder above, and the cells and top boxes as before.

PREPARING THE COMB FOR CELLS.

I prefer a last season's built comb that has been bred in, after getting it well filled with eggs from one of my breeding queens in the usual way. I cut down on one side to the midrib on each side of every fourth row of cells with a thin budding-knife, and scoop out the three intermediate rows with a broad bradawl; then one out of every three eggs in the rows is left, and the others killed with a splint that has been dipped into wax. I don't touch the other side of the comb. In very hot weather the

comb may need a center support. Securing such a large number of cells, one can well afford to discard any that appear to be below a high standard.

Auckland, New Zealand.

[Dr. E. F. Phillips, of the Bureau of Entomology, after seeing our footnote calling attention to the similarity of this plan to the Alley method, stated that he obtained it from Mr. I. Hopkins, of Australia. He thought so well of it that he placed it before the beekeepers of the New York State convention some two or three years ago.

While we admit that as many as eighty or a hundred good cells *may* be secured in one batch, experience in rearing thousands of queens every season has shown us that it is better not to try to raise over two dozen at a time. One may suppose that the cells are all good; but our experience seems to indicate that queens raised from the cells where so many are built at a time are likely to be short-lived. We *can* raise a hundred cells in a batch—have done it time and again, years ago.

There may be some advantages in the method here described, particularly for beginners and professional honey-producers who have not the time to learn the intricacies of the art of raising cells by the grafting plan in wooden cell cups; but our men who raise queens by the thousand say the other plan is too slow. But we are going to get them to try it over, following very carefully Mr. Hopkins' directions as here given. We will report results.—Ed.]

A SWARM CAUGHT BY THE USE OF OIL OF ANISE

BY EDWIN A. SMITH

My brother and I once caught 76 swarms in one month. We take any kind of box that will hold frames, put starters in them, then put the prepared boxes in trees. We put a drop of oil or anise in the box long before a swarm finds the place.

I never saw a swarm of bees until last spring. When my brother and I started, we thought we would try it, so we put out boxes and caught 72 swarms. We sold \$136 worth of comb honey, then sold the bees, and started in new last month. California is the place to catch runaway bees.

I get the oil of anise at a drugstore. Before I start out I put a drop or two of anise in the box, then I locate the boxes in trees, under brush, or any place where the sun doesn't strike them in the heat of the day. I can catch twelve swarms by the use of anise where I could catch only one

without. Last year I put out boxes without any thing in them but the anise, and caught 72 swarms out of 75. I look at the boxes every week, and in those that have no bees I put another drop of the anise on the alighting-board.

Whittier, Cal.

[The use of oil of anise is mentioned in the A B C book, under the head of "Bee-hunting." I have used it, but did not find it of more benefit than burning combs, etc. As the perfume from the anise, however, would last for several hours, and perhaps days, it would be an advantage for the decoy.—A. I. R.]

SOME CALAMITIES IN THE APIARY

Flood and Suffocation

BY E. F. ATWATER

The first serious mishap which occurred among our bees was in 1905, when, in addition to a crop failure, an entire yard was almost destroyed by water. This apiary was located in a bend of an irrigation canal, where it was a little low; but as the ground was dry, and had never been irrigated, we did not even have the entire yard on the four-inch Miller stands which we were using at that time. Just as the flow was due we visited that yard, and were greeted by a stench not unlike that from foul brood, and almost overpowering in its intensity. Upon examination we found that almost every colony had suffered severely, while some were dead. During the night a rancher had turned into this canal 400 inches more water than it was built to carry, and the overflow came to our apiary. The weather was warm, the colonies strong, so that every tight hive had its entrance closed by the water. The bees had all but suffocated, and the brood was scalded by the confined

A large swarm caught by the use of a little oil of anise in a box located in a tree.

One of E. F. Atwater's yards, Meridian, Idaho, that was practically destroyed by fire started by a spark from a passing train.

heat. The colonies in hives that were old and gaping were but little injured.

Another experience which is little less than a calamity is when an entire yard must be shaken for foul brood. This has happened twice in our 16 years of beekeeping.

In June, 1909, a spark from a passing train ignited the grass in our Taylor yard. The tenants on the ranch fought the fire as best they could, so that we lost but few colonies outright, though a large part of the field force was burned as they came in from the fields and tried to enter their hives. Where there were open ventilators the flames sucked in at the entrances and up like a chimney. Part of the debris is shown in the picture. The three children standing at the left are the son and two daughters of the good German tenants who took an active part in fighting the flames. Notice the utilitarian costume of the two girls.

In March, 1910, we were hurriedly called to the phone and informed that our Bennet yard was fast being flooded. It was almost night, but we secured help and drove to within a mile of the yard, where the road became a torrent of icy water, with an ice-jam just below. Here we left our team and took to the track of the electric railway, and finally arrived at the yard where the water raged, from a few inches to two feet deep.

The wintering sheds were demolished, tar paper torn away, and, leaving one colony in the water, two or three were piled on top over the entire yard. As we lifted each hive, gallons of icy water poured out of the

entrance and down my clothes as I handled the front ends of the hives. After we piled up the entire yard in this manner we went back to our team where we partially dried our clothes over a fire and drove home.

The results were surprising. The flood abated soon after we left the yard, and only one colony was lost outright; and as there was but little brood at that time, the yard built up and yielded a normal crop. We found that the water simply drove the bees to the top of the hives (part were two-story), and if any little opening was found in quilt or cover, a part of the bees would be quietly clustered on the outside of the hives.

Meridian, Idaho.

CLIPPED QUEENS AND ARTIFICIAL SWARMING

A Clipped Queen that Lived to be Eight Years Old

BY J. W. NICHOLS.

Having been interested in the articles on clipped queens by H. E. Harrington, p. 143, March 1, and by Harry Lathrop, p. 285, May 1, I wish to add a word in line with what Mr. Lathrop has said. While I am a beekeeper in only a small way I have clipped queens for fifteen years, and have always been successful. Unlike Mr. Lathrop, however, I clip both wings on both sides short, so that, when a swarm issues, the queen will not leave the entrance-board, but will be found in front of the hive where she can be easily caged, and the hive exchanged for a new one, ready for the re-

turn of the swarm, which occurs soon after they find themselves without a queen.

I think that, in many cases, the disposition to swarm is clipped with the wings. I once clipped a two-year-old queen that lived and worked for six seasons, without taking out a swarm or having a queen-cell built. She worked seven seasons with her own bees—two seasons unclipped and five seasons clipped—and in the eighth season she was put with a weak stand; and in July, after they were strong, she died of old age. Can Mr. Harrington tell why those bees did not discover in all those years that she was maimed?

I clip my queens in the queen-rearing hive, and introduce them clipped and without caging. Caging queens in the hive belongs to the methods of the past.

I cage the queen in the afternoon, and leave the cage on the frames of the small hive; then, after sundown (always), when the field workers are all in, I take the queen in the cage to the large hive; open it, and give the bees a little smoke; then let the queen run down with the bees, shut the hive, and do not open it for three days. The queen then will be safe. I have not lost a queen, introduced by this plan, for ten years.

TWO PLANS FOR MAKING ARTIFICIAL SWARMS.

I am not a lover of natural swarming, so I clip all my queens, cut queen-cells, and make my swarms artificially by two plans. The first is old, and the most simple, and is one which I use only after the honey-flow is in, which is usually some time in July. At nine o'clock some fine morning, when the field workers are beginning to come in, I take from a strong stand a frame of brood having fresh eggs, paying no attention to the queen, and place it in a hive with seven frames filled with full sheets of foundation, putting one frame with foundation in the old hive in place of the frame I have taken out. Then I remove the old hive to a new stand, and place the new one on the old stand in time to catch the field workers. If the queen is left in the old hive she will have no disposition to swarm when robbed of her bees, and will destroy the queen-cells, if there are any. If she is in the new hive on the old stand, the first young queen out in the old hive will do the same.

With the other plan, which I now use the most, I do not disturb the working colonies. Early in the season, as soon as there are drones, I take four queen-rearing hives that hold three brood-frames each, dividing among them the frames from an eight-frame colony, giving each hive one frame having fresh eggs. I then put in each hive a third frame having comb or foundation. The old

queen will be in one of the four hives. When the other three parts of the colony find themselves queenless they will build queen-cells and rear a queen for themselves. As soon as the old queen has the three-frame hive filled so that she wants more room I place her in an eight-frame hive having five frames of foundation. When the queens in the other three hives have hatched, mated, are laying, and want more room, I place them also in eight-frame hives having five frames of foundation. By this plan I disturb only one colony and add three; but if I have a colony that has the swarming fever and will not stay, I take it to a new stand and place one of the young queens with her bees on the stand which has just been vacated. The field workers will go into the hive with her, and live happy ever after.

Dayton, O.

AN EARLY TYPE OF STEAM-HEATED UNCAPPING-KNIFE

BY ARTHUR C. MILLER

The accompanying photograph is of a steam-heated uncapping-knife which the writer had made and experimented with in the summer of 1896. A rubber tube led from the steam-generator to the nipple nearest the handle, and the steam was allowed to blow freely from the other nipple. Later the second orifice was reduced with a

Arthur C. Miller's steam-heated uncapping-knife which he had made in 1896.

grooved plug. So far as the writer knows, it was the first steam-heated uncapping-knife in existence. It was far from being the perfect device now on the market, but it served to demonstrate the principle, also to inflict sundry burns, and was soon laid aside for a good old-fashioned Bingham knife. It was experimented with on two or three subsequent occasions, but was finally put among the "curios" of the "has been" collection which all good bee veterans possess.

Many persons saw this knife in operation when I first made it, and I exhibited it at Toronto several years ago, and I think at Amsterdam, N. Y., the year before. The man who made it for me is in business just across the street from this office. I recall

the date, because it was the same year I sold some real estate.

I do not use any knife now—too slow.

Providence, R. I.

[Mr. A. C. Miller was probably the first one to use steam for heating an uncapping-knife; at least we do not find any record of any earlier user. Some ten years afterward the steam uncapping-knife was used in Europe, as is seen in one of the European bee journals (*Apicoltore* for June, 1907, page 110, but the principle of heating a knife by steam for meat-chipping purposes was patented by O. Gardner, July 8, 1873). It was not till two years ago that a steam knife for uncapping was placed on the market in this country.

It is but fair to say that some like it and some do not. Steam will keep it hot continuously; but the rubber tubing, which is more or less in the way, and the extra weight of the knife, are objections with some. We have been testing the steam knife alongside of an ordinary Bingham knife dipped in a pan of hot water. Some of our boys prefer the steam knife, and others prefer to be unfettered by any attachment. We have about concluded that the man who starts with a steam knife would not use any other; and one who starts with one of the common kind, heated in a pan of hot water, may or may not want to change over to the steam knife. There are many (and they have worked the old way) who believe that the steam-heated uncapping-knife is miles ahead of any other form of uncapping-device.—ED.]

NUMBERING POSITIONS INSTEAD OF HIVES

Record-Book Method of Numbering Hives

BY S. E. MILLER

On page 328, June 1, Dr. Miller is still hammering away on the hive-number question. I am surprised that he will continue fussing with numbers attached to the hives when there is a better and simpler way, and no hive numbers are needed except in the record-book. That one-inch nail driven one-third of its length into the hive, and two-thirds out—why, doctor, if there is a nail sticking out of a hive that I am working about I do not feel well until I get the hammer and pull it out. Then why bother with a tag of any kind that has to be changed every time there is a change of some kind, caused by swarming, etc.?

If Dr. Miller can pick a flaw in my system of numbering hives, let him fire away. Some years ago my method of arranging colonies in the apiary was illustrated in the

A B C of Bee Culture. They are arranged in groups of five colonies, and I may here state that I have made a slight change since—that is, I have no colonies facing north—thus:

The group in the southeast corner of the apiary is A (letter A), and the southeast hive is A1. The next west is A2; still west, A3. North of this is A4, and the one at the northeast is A5. B is the next group west of A, and the numbers 1 to 5 are repeated in each group, the groups being arranged like this:

etc.	K	J
I	H	G
F	E	D
C	B	A

Now, the hives are not numbered; but the spot where each hive stands has an imaginary number. These numbers are recorded in the book in alphabetical order, and are indexed for each group by cutting away a part of the page of each fifth set of leaves, similar to the way a dictionary is indexed.

B2 casts a swarm, and I see it issuing. I open the record at B, which is B1. I turn one leaf and have the record of B2 before me. At a glance I can see whether the queen is clipped. I see that she is, and proceed to the hive with a cage; find her, and place her in it. While the swarm is in the air I remove the colony and place a hive prepared as I see fit in its place, and lay the cage containing the queen at the entrance. I have simply set B2 a little out of the way for the present.

I now look over the yard and see a vacancy at G5. Note here that G5 has its proper place of record in the book, and it is also fixed in my mind so that if I should consult the book without being in sight of the apiary I see that G5 is marked vacant.

G5 is some little distance from B2, so that the new colony or swarm is not likely to locate the parent colony; and some of the field bees leaving G5 will likely return from the field to B2, thus further strengthening the new colony. Now for the record:

B2 is practically a new colony, but it is still B2, and will read like this: "June 10, cast swarm; have clipped queen; hived

her on 10 frames with 3-in. starters;" or, to make it as I do in practice, it would read: "6-10 east swm.; have el'p — hived on 10 frames with 3-in. starters." (A dash is my abbreviation for queen). I will now write the record for G5: "6-10, parent colony from B2; have 2 or more sealed queen-cells, and several unsealed;" or to abbreviate again, it would read: "6-10, par. col. B2; have 2 sc and several unsl."

Queen-cell is written c, and I may state that I have quite an extensive code of similar abbreviations.

In looking over the record some four or five days later I see when I come to G5 that I must, within a day or two, remove the surplus of queen-cells unless I want to take chances on having after swarming, which I certainly wish to avoid.

It will be readily seen that this method may be easily adapted to any arrangement of hives. If placed in straight rows the numbers can run 1, 2, 3, up to any number.

By preserving the records it is possible to trace back any colony to its original stock or parentage, provided there has been no break in the record by supersedure unknown to the beekeeper. This would not make any material difference unless superseded by a queen of inferior stock entering the hive, and killing the reigning queen, which, I dare say, does not occur frequently.

Now, Dr. Miller, do not let those tags worry you any longer. If my memory serves me well it was your writing which caused me to discard slates and adopt the book record. Why, then, do you not make use of the book to its fullest advantage and greatest availability? I can locate any colony in the apiary from any direction. It is not necessary to walk around to the side or end of the hive that the number is on. There is no number on it.

Rhineland, Mo., June 10.

[If there were a hundred or more colonies in an apiary this scheme would hardly be practicable. Anyhow why not use your scheme and number tags both?—Ed.]

BEEKEEPING IN JAMAICA

Drouth Causing very Poor Crops

BY F. A. HOOPER.

This country, once famous for the production of fine honey, and in large quantities, is now producing less and less each year. Up to the year previous to that of the earthquake, which occurred in 1907 (when the city of Kingston was totally de-

stroyed and hundreds of the inhabitants of the island perished), a failure of the honey crop was unknown.

This year, 1912, is the worst that beekeepers have experienced since beekeeping was introduced in the island on a commercial scale by Hooper Bros. in 1892.

Taking an average of the whole island, each colony has produced only 14 lbs. of extracted honey this season. Beekeepers are now anxious to know if the poor seasons will continue as the years roll on. In my opinion we have arrived at the climax, and beekeepers will see a change for the better, commencing next year. Our weather prophet predicted five years of drouth would follow the earthquake, and so far he is right, especially this year.

During our best months for honey, which are February, March, and April, the weather was so dry that there was not sufficient moisture in the earth and atmosphere; hence the few flowers that did open had no nectar. If we had had our usual rainfall last year, the early drouth this year would not have affected the honey crop, for there would have been sufficient moisture in the earth; but as it was, even the deep-rooted trees failed to bloom.

Beekeepers need not fear about not ever again securing large yields of honey. The flowering plants and trees are all alive, and are just waiting for the regular rainfall to bloom again as they have done before.

The rivers which are now mere streams will be rivers again; and the streams which are now nearly all dry will again trickle down the mountain sides. It is only a matter of a little patience.

Four Paths, Clarendon, Jamaica.

THE AVERAGE CROP IN CALIFORNIA

Are Mr. Chadwick's Figures Too High?

BY J. W. KALFUS

On page 297, May 15, P. C. Chadwick gives some figures in regard to the honey yield of California. I am afraid if his figures could be proven it would cause such a rush to our State that there would not be standing room for beekeepers. While I have heard that 1884 was an exceptionally good year, we must not overlook the fact that that was a long time ago, and there were probably not one-fourth as many bees in the country as at present. However, I am of the opinion there are not many beekeepers in other States, at least, who will believe that 700-lb. story. In 1905 I was living at San Luis Obispo, and, of course, can not say as to what the yield was in

Southern California; but I know of a number of men whose crop fell short of 300 lbs. average. I heard of several men who got 300 lbs., and one who got 350; but I afterward heard he extracted his honey so green the cans "blew up" and he had to put it back in the tank and ripen it. I have no doubt that a few apiaries made more than the 350 mark, but they are few and far between. My average for 1905 was 52 lbs. per colony. In regard to his estimate of 100 lbs. average, I think he has put that entirely too high. In making these estimates for publication I think we should be very careful, and not put them too high and thereby mislead any beekeepers who may want to settle among us. Now, I don't want any one to think I am trying to keep other men out, for I am not; but I believe in giving the facts just as they exist; and if we have no way of knowing the facts we had better put the figures a little below the average than above; and then if any eastern beekeepers should settle among us, and not do quite as well as they expect, they would always be blaming us for misrepresenting things.

During the last five years I had an apiary in Los Angeles County in what is considered one of the best sage locations in the State, and my average for the five years was 71 lbs. per colony. But methinks I hear Brother Chadwick say, "The trouble was with you. You don't know how to keep bees." While I admit this is true to a great extent, still when I look around me and see such men as L. E. Mercer, M. H. Mendleson, and J. F. McIntyre, who have not done any better in that time, I am led to think the fault is not altogether my own. I mention these men because they are among the foremost beekeepers of the country, and are well known to the readers of *GLEANNINGS*. About a year ago Mr. L. L. Andrews, of Corona, who has several hundred colonies, wrote me his average yield for five years was 60 lbs.; and Mr. Geo. L. Emerson, who operates several hundred colonies at Fullerton, wrote me his average for the same length of time was 58 lbs. I also had letters from several other men in the Southern part of the State whose names I can not recall; but not one of them claimed an average of 100 lbs. There is no doubt but there are some men who have had an average of 100 lbs. for the past five years; but there are so many whose average has fallen below 50 that it cuts their average down considerably. For my part I think an average of 60 lbs. for Southern California during the last five years is nearer correct than 100.

Bishop, Cal.

[Mr. Chadwick replies:]

The chief apprehension in the above criticism seems to be that it might cause an influx of Eastern beekeepers who would be disappointed in not getting so high an average after casting their lot with us. Referring back to the issue above mentioned, note this sentence, "taking into consideration that some years, outside of the orange and alfalfa districts, there is practically a total failure."

This estimate was based on information gathered from many beekeepers from various points, together with the experience and observation of the writer—not for a period of five years, but since 1884. Quite true, conditions have changed since the latter date, and no such phenomenal yield may be expected again, because of a lack of flora then bountiful, and because there are many more bees now.

Mr. Kalfus quotes Mr. Geo. L. Emerson in producing his proof, Mr. Emerson being the man who informed me of the 700-lb. yield for Orange Co. in 1884, and I have no reason to question so eminent an authority.

My average for the past five years has been under 100 lbs.; but for the past seven years, including 1905, it exceeds 100 lbs., though in 1905 my average was only 250 lbs., while others, to my knowledge, more favorably located for a late flow, secured nearly 400.

The occasional (not frequent) heavy seasons are what runs up the average, and should not be taken by any means as a season's average.

These heavy seasons are what keeps up the hopes of the California beekeeper who waits for the realization through seasons of dearth and heavy loss and is finally rewarded when his forces are depleted, and in the poorest possible condition to realize the most from them. I still believe my estimation is not far from correct; but it must not be forgotten that this includes some *very* thin and a *few* very fat seasons.

P. C. CHADWICK.

AN ANALYSIS OF BEE-BREAD

BY RUTH L. PHILLIPS

The following analysis of bee-bread was made by me during the summer of 1911 in order to ascertain the nature of this substance and its relation to the growth changes in the nerve cells of the ordinary Italian bee.

As one would expect, there is a large proportion of water, 12.75 per cent, in bee-bread. The bulk of the substance is pro-

teid, the nitrogenous portion of the food. Of this there is a percentage of 64.4 per cent. This high proteid content is not strange when we consider that pollen is mainly protoplasm, a substance largely made up of proteid. There are 9.23 per cent of fat. This fat is remarkable in that some of the oils composing it are very volatile, and have a penetrating disagreeable odor. There is a sugar content of 9.5 per cent. This is 1.3 per cent cane sugar and 8.2 per cent sucrose. A large part of this sugar comes from the honey used in mixing the bee-bread. An analysis of pollen alone would be necessary to ascertain the exact amount. I was surprised to find considerable wax, 3 to 5 per cent, in the bread. Dr. E. F. Phillips believes this to have come from careless removal of the pollen from the cells in which it is stored. However, as I was particular to avoid that very thing I believe that most of the wax was a part of the bread. Dr. Phillips maintains that pollen will keep without preservatives being used. I endeavored to preserve dandelion pollen in the laboratory, but failed because of mold, and it would seem that the controlled conditions in the laboratory would be better adapted for keeping pollen than those obtaining in the hive. I therefore believe the wax is used as a preservative.

The following is a tabulated *resume* of the analysis:

Water, 12.75 per cent; proteid, 64.4 per cent; fat, 9.23 per cent; sugar, 9.5 per cent (cane sugar, 1.3 per cent; sucrose, 8.2 per cent); wax, 3 to 5.00 per cent.

Syracuse, N. Y.

WHY THE BEES DID NOT EAT THE FRUIT

BY BENJAMIN W. DOUGLASS

[Mr. Douglass was formerly State Entomologist for Indiana. Politics threw him out of office. He is now largely engaged in fruit-growing, and is editor of *The American Horticulturist*, published at Indianapolis. He ought to know what he is talking about, and does.—Ed.]

Bill was always a hard person to get along with, and all of his neighbors avoided contact with him just as much as possible; so I was not unprepared when he came to me with his tale of woe. I keep bees, and Bill has a few peach trees and some grapevines. I also have a few peach trees—in fact, several thousand more than Bill; but that does not keep Bill from thinking that he is the original and only fruit grower. Bill was angry. His peaches were being eaten up by my bees, and his grapes were being ruined. Something had to be

done about it. His entire crop was threatened with destruction, and he demanded justice. I realized that I faced a diplomatic problem, and so I proceeded with caution.

"Bill," said I, "how many times did you spray your peaches this spring?"

"Nary a time. My peaches don't need sprayin'. They was always all right until you brought your pesky bees out here."

"Well," I pursued, "was not this past season a particularly severe one on peaches, inasmuch as the warm wet weather has caused them to rot more than usual?" He admitted that it was. "Now, Bill," I said, "did you ever actually see a bee eating a hole in a perfectly good peach?"

Bill is fairly truthful, particularly when he suspects that you have the drop on him, and he hesitatingly admitted that he had never seen a bee at work on a perfectly sound peach, but that their first work was, without exception, at a rotten spot where the skin was soft or even broken. With this admission I took the liberty of crowding Bill into a corner where he could not get away, and proceeded to give him a lecture on the way bees "damage" fruit.

It is practically impossible for a honey-bee to "eat" through the skin of any of our common fruits; and if they do any damage it is purely secondary in nature. If the fruit grower would turn his attention to the proper methods of caring for his crop he would find that the bees will not bother him; and in place of fighting the beekeeper he would welcome him to his locality.

The experiment has been often tried, of keeping hungry bees in a cage with some perfect fruit. They will not touch it. This is not because of any angelic disposition on the part of the bees, nor because they are possessed of more than human sense of property rights, but simply because the Creator did not intend that bees should eat hard things; and the skin of fruits is hard. The bee's mouth is a soft structure, built for sucking the nectar of flowers. It would be quite impossible for such a mouth to "bite." Imagine boring a hole in an apple with a soft-rubber tube. That is what a bee would have to do if it did not depend on other insects to break the skin on it first. Some fruit growers argue that bees "sting" the fruit and then suck the juice. While such a performance is anatomically possible, there is no record that bees ever use their sting for this purpose.

Of course, Bill offered objections from time to time, and in the end I do not think that he was altogether convinced that the peaches had not been "eaten" by my bees. Just to keep peace in the family I gave him a couple of sections of new honey, and he

went home feeling satisfied that he had done his duty by his orchard. At the same time I knew that a spray-pump was lying out back of his barn, rusty with neglect. His peaches didn't need it. He had tried it, and he knew.

SPRAYING IN BLOOM KILLS BEES

Half the Bees in Pecos Valley, N. M., Killed this Spring

BY R. B. SLEASE

The editorial, June 15, on spraying fruit trees while in bloom, makes my blood boil. Of course, these men claim that, under certain atmospheric conditions, the spraying did no harm to the bees. Now, there are only three conditions under which it would not hurt bees: 1. Plenty of other flowers that bees would rather work on; 2. Weather so cold that the bees were not working; 3. Weather too wet for bees to be out. Now I have had bees right beside 600 acres of orchard for the past 15 years, and the last 9 years the orchardists have been spraying, and during this time I have had a little experience. In 1904 they tried spraying in bloom. I lost about half of my bees and brood, but only about 25 colonies perished outright. Bees did not get in shape to do any thing till Aug. 1. After this I did not have any serious loss (as the orchardists did not spray quite so early) till 1909, when I lost about 25 or 30 per cent of my bees and brood, and some 30 good queens; but by requeening promptly I lost only a few colonies, and the bees got in shape to make honey by July 10.

In 1910 and 1911 I had some loss, but not very serious. In 1912 I went over all my bees the first of fruit bloom, and found I had 163 hives in fair condition, with from two to six frames of brood. Now (July 2) I have 121 hives with some bees in. At least a third have a patch of brood from two inches in diameter to as large as the hand. The rest have from half a frame to six frames of brood.

I have never had foul brood in my yard, and find dead brood only when fruit trees are sprayed in bloom. I then find plenty of dead bees all over the yard. I had some chilled brood one spring when we had a cold wave and snowstorm April 20 and 21, 1907.

So far as I can learn, at least half of the bees in Pecos Valley were killed by spraying this spring. If spraying in bloom does not kill bees in New South Wales it is very different from the Pecos Valley of New Mexico.

Roswell, N. M., July 2.

HIVES NUMBERED BY POSITION OCCUPIED

BY LOUIS MACEY

I see Mr. Scholl, May 15, is voicing the need of a satisfactory hive number "that is cheap and readily transferrable from one hive to another."

When I got above 20 hives the "identity" question began to bother me, and I went to work and painted numbers on the hive fronts in consecutive order as they then stood; but as time went on, and I found myself putting colony No. 1 into hive No. 32, so as to clean the propolis and burr combs out of their old home, and setting hive 6 away off in another place, and the swarm in a hive numbered 41 on the old stand, etc., I found I was getting a good many different kinds of mixups, besides giving my apiary a very much jumbled-up appearance.

Some of our beemen tell us they are doing such a rushing "big business" that they can't afford to bother with any such thing as a record-book; but I think most of us find time to keep track of our queens and the different colonies and their changes; and in any case the main thing we want to identify is not the hive but the *hive location*, or what some call the *hive stand*.

I have evolved a plan for this that is simple, inexpensive, convenient, and as nearly everlasting as the apiary itself; moreover, this number automatically puts itself on. My hives are in pairs in parallel rows, "breaking joints" like this:

```

□ □      □ □      □ □      □ □      □ □
    □ □      □ □      □ □      □ □
□ □      □ □      □ □      □ □      □ □

```

Each hive has two numbers—an individual hive number and a *row* number. That the hive number comes first is all I have to remember. The north row is 1, and the first hive is 1-1, or "first hive, first row;" and the 14th hive in the first row automatically numbers itself 14-1, as the next to the last hive likewise proclaims itself 13-3.

I occasionally paint the number on some of the alighting-boards to save counting; but unless the rows are very long, that is unnecessary. I now have six rows, and find it easy to increase either the length or the number of the rows without throwing the numbers "out o' kilter."

The even-numbered hive is always the east hive of the pair, and the odd numbers are always the west hives in each pair.

There are also several other advantages; and the longer I use this plan the better I like it; I don't expect it to suit all conditions, but give it for all it is worth.

North Platte, Neb.

Heads of Grain from Different Fields

Hive Numbers Printed on White Enameled Metal Tags

On page 296 Mr. Scholl asks for a hive number which is satisfactory besides being cheap and durable. I have for some time been using a number of my own make which calls for a very little outlay of either time or money, and which has given entire satisfaction. I got a piece of heavy galvanized tin, and with a pair of tin shears I cut it into rectangular pieces about $2\frac{1}{2} \times 3\frac{1}{2}$ in. (though for numbers of more than two figures the tags would have to be longer). I rounded off the sharp corners; then with a large nail (about 16 penny) I punched a hole in the middle of one of the long sides about $\frac{1}{4}$ inch from the edge. I then dipped them in white enamel paint and laid them on a board to dry, with the rough edge of the holes up. The numbers should go on that side, as the tags will then lie flat against the front of the hive. When the enamel is dry, but before it gets hard, paint the numbers in black with a small marking-brush. A little practice on a board or a paper before beginning on the tags will result in better figures.

To hang on the hive, select small wire nails, the heads of which will just pass smoothly through the holes in the tags. Drive the nails into the hive fronts so that about $\frac{1}{4}$ inch projects. The rough edge of the hole in the tag prevents the latter from jarring or blowing off, yet the tags can be slipped off or on by the apiarist in a moment.

Louisville, Ky., May 28. J. B. CHRISLER.

Hiving a Swarm Quickly

Seeing an account of hiving a swarm by an expert, in the May 1st number of GLEANINGS leads me to write an account of the quickest work in hiving I have ever done. On May 4, this year, I was called on the telephone and informed that a large swarm had settled in the rear of a friend's residence about three city blocks from my home, and that the bees, being strays, were mine if I would have them. I had an engagement in less than an hour, so my first idea was to decline the offered bees because the time was so short; but the bee fever was too strong to be overcome, though I have had it for more than forty years, so I rushed home from my office, quickly secured a frame of unsealed brood, laid it flat on the bottom of a very light box having a hinged lid on it, walked rapidly to the scene of action, where I found the swarm clustered on a small branch of a chinaberry tree, in easy reach. Without veil or smoker I quickly cut off the limb without jarring off a single bee; laid the cluster in the box still on the limb, closed the lid, and away I went with my prize. Arriving home I secured a single story, filled with empty combs; placed the limb over the frames, after having inserted the frame of unsealed brood; gave them a slight shake, and after some of the bees had begun entering thus from the top, and when they got well to going, I shook the remainder off the chinaberry limbs, and they were in the hive almost instantly. There remained nothing but to put on the top and rush to the meeting, where I arrived with five minutes to spare.

It is well worth while to emphasize the use of a light box, made of tough wood, and hardly as thick as pasteboard to catch and carry to the proper place a swarm, and also the great advantage of a frame of unsealed brood laid flat on the bottom. I just happened to have this box, and it had never occurred to me to use it this way until this occasion arose.

Carrollton, Ga., May 14. L. K. SMITH.

A Quick Way of Killing a Surplus of Drones

I have read in the bee journals a description of a queen-sieve and its uses, but never saw a drone-sieve described, although the occasion for its use may arise in every apiary sometimes. Here is one that I have been using with good results. I nail a queen-excluder to the bottom of an empty hive body, and set it on top of another empty hive body close to the hive to be operated on, and shake into this sieve bees and drones from every comb except the queen, and cover it as quickly as possible. After replacing the combs I put a Porter bee-escape on

top, and on this the sieve with the drones, after having brushed off the bees that have clustered on the under side of the sieve. Next morning you find all the bees that remained with the drones have passed down the escape, and the drones on their backs kicking the bucket. To shorten the agony of death I put the sieve over a teaspoonful of burning sulphur, and in a minute it's all over.

Monterey, Cal., May 14. WM. A. SEDDING.

Queens Caged in a Hive

1. Is it safe to keep ten or fifteen untested queens in an upper story (caged) separated from the old queen by an excluder for, say, a week or ten days, until convenient to make nuclei? 2. Is there any preventive or cure for white diarrhea in young chickens?

Slate River, Ont., May 15. J. M. MUNRO.

[The longer you keep queens caged, the worse it is for them. Sometimes they will die in less than a week, and again they will live a month or so. It depends a good deal upon the bees of the hive, and also upon the vitality of queens themselves.]

The poultry journals for a year or two past have been full of remedies for the white diarrhea, but I believe the general decision has been that prevention is better than cure. I have never had any experience with it, and my impression is that if the chickens are put often enough on new ground, not too many in one lot, and kept out in the open air and in the sunshine as much as possible, there will be no such trouble. Filthy quarters and rearing large numbers of chickens on the same ground are pretty sure to start diseases of this sort.—A. I. R.]

Dual Introduction

Please give the plan of dual queen introduction as invented by Mr. Alexander, and printed a few years ago in GLEANINGS. JOSEPH BRAUN.

New York, June 30.

[Briefly, the dual plan of introduction is as follows: You introduce a virgin queen by the usual cage plan, and at the same time cage another virgin in the hive with a piece of tin over the candy. When the first virgin has been released, and is laying, remove her, and at the same time remove the tin from the candy of the other cage. Then cage a third virgin in the hive with tin over the candy, etc.]

If you have reference to the plural-queen plan, as mentioned by Mr. Alexander in his book, we may say that this is quite a complicated method; and, although it has been tried out by a good many beekeepers for several years, there is practically no one in the country who is following it at the present time, the reason being that in almost every case the surplus queens will be killed after the honey-flow.—Ed.]

A Stubborn Colony that Will Not Accept an Introduced Queen

I have a colony of bees that are kind and gentle. They never seem inclined to sting, but they simply won't have an Italian queen with them. Last year I purchased three tested Italian queens and introduced them according to directions on the cage, and a few days after they released them we would find them carried out dead in the drone-trap.

Last fall I purchased one of your A B C books and went according to directions. This spring I got a tested Italian queen. About two months ago they let her stay with them about four weeks, then I found her carried out dead. As I am anxious to get a colony of Italians, two weeks ago to-day I received another queen, and all seemed well until today, when they carried her out; but I happened to be there, and rescued her all but dead. Now I write to you for advice. There is no queen in the hive, as I looked them over several times. Before they killed the first one this spring they started nine queen-cells. Some of them were sealed over when she died. They are a good quality of hybrids.

Marietta, Ohio, July 2. GEORGE AMANN.

[One in a great while we run across a colony like the one you describe, that seems determined to kill every introduced queen within a short time after she gets to laying. We recall we once had such a col-

ony; and as often as we would introduce a queen they would kill her as soon as she had laid a few eggs. We finally let them rear a queen of their own from the eggs left by the last queen; and this one they allowed to stay in the hive; but why, we can not understand. We do not know of any thing better you can do than to let this colony raise a queen of its own. If they kill her, we would brimstone them. Hybrid colonies are more apt to cut up capers of this kind than pure bees of either race. —ED.]

Uniting by the Newspaper Plan

I have ten colonies of bees—six strong, one fair, and three small ones, about a gallon or a gallon and a half, and I want to join the fair one and one of the small ones and make a strong one out of it, and the other two together will make a fair or strong one. The one that I am going to join is in an eight-frame hive I made myself. It has a movable bottom. The fair one is in an eight-frame bought hive, and the other two are in a box. The one that I am going to join first is in the hive that I made. I am going to make a hole in the bottom about two inches across, and put it on top of the small one in the box, and put a hole in the lid of the box about the same size, with a screen on top of the box, and set the other hive on top of it, and leave it on two or three days or a week—long enough so that the bees on top will have the same smell as the one in the box, and then take the screen off and put a perforated zinc so that the bees will go from the box to the hive on top, then the queen can't go up; then if they don't go up I can shut up the bottom doorway in the box, and they will have to go up to fly after they get joined. Then I want to transfer them to a ten-frame double-wall hive. When will it be best to join and transfer them?

The other two, I want to put one in the box with the one in the eight-frame bought hive. What is the best way to join them? The ones that I want to transfer into the double-walled hive, will it be best to put them in the frame full of foundation or the frame with the bees and combs on?

Leigh, Neb., June 26.

WM. F. GLANDT.

[We are not sure but that it would be better for you to follow the newspaper plan rather than the wire-cloth plan which you refer to. The newspaper plan is really simpler. Remove the cover of the lower hive, place a single thickness of newspaper on top, and set the second hive on top minus the bottom-board. By the time the bees gnaw through the paper the uniting will be so carefully and slowly done that there will be practically no fighting, and the moved bees, says Dr. Miller, will stay where they are put. A little later you can easily transfer the bees to a 10-frame hive by picking out 10 of the best combs that contain brood and some honey, and merely lifting them into the ten-frame hive. Then shake the bees from the rest of the combs from the empty hive before the entrance of the ten-frame hive which should now stand on the old stand.]

Regarding the other colony that you want to transfer to the double-walled hive, if the combs are straight and practically all worker size of cells, it would not be necessary for you to shake the bees on new frames of foundation; although if there were any trace of disease or suspicious brood in the old combs it would undoubtedly pay you to shake the bees on to the new foundation.—ED.]

Supersedure of Queens; How to Recognize Supersedure Cells from Swarming Cells

I have a colony that is an exceedingly powerful one, built up from a swarm in the latter part of May. They began working in splendid style, drawing out foundation, and then for some unaccountable reason they began building queen-cells, which I as persistently continued to cut out. As I know now, it was a case of supersedure. I found the queen, only a year old, clipped, ten or twelve feet in front of the hive one day, surrounded by only a half-dozen bees, and as she seemed to be in good condition I went through the hive very carefully, cut out every appearance of a cell and restored her. There was absolutely no pretense of swarming, as one or two people were in the vicinity of the hive all day. About three weeks later I found the clipped queen lying in front of the hive dead; and in going through the colony I found no eggs, no queen-cells, and no queen. Naturally I then concluded the

queen had died, and that there was nothing left in the hive from which to raise a young queen. Imagine my surprise the other day, after putting the bees through a "strainer," to find a magnificent young queen just beginning to lay. Where they raised her, and how they did it, I can not conceive, as I made it a custom to go over every comb in the hive once a week, and I did this very thoroughly and got out every cell I could find.

The new queen I introduced by caging her on the face of the comb, and every thing is lovely. The bees are working splendidly. In the meantime, I could not make up my mind to destroy the young queen, so gave her a couple of sections of honey and young bees, and started her to housekeeping in another hive.

This matter of supersedure is one of great interest to beekeepers, and incidentally must be one of the most puzzling problems by which the beekeeper is confronted—not as to why the bees supersede the queen, but rather how the beekeeper is to determine whether the bees are building cells with the intention of swarming or with the intention of superseding the old queen.

Detroit, Mich., July 10.

J. M. FRANCIS.

[Supersedure may take place almost any time of the year, or at any time when the queen shows disposition to fail. This failure may be due to old age, to injury received while in the mail, or to rough treatment she receives at the time she is introduced.]

It is not possible to detect the difference in appearance between supersedure cells and swarming cells; but when we find cells built during the swarming season we naturally conclude that they are swarming cells—that is, providing there is a good queen in the hive already. But when we find a laying queen apparently failing, and nicely built cells in the hive at any other time of year, we usually call such cells supersedure cells.

The size of worker bees will vary a good deal according to conditions. During the midst of a heavy honey-flow, and especially at night, after the bees are quiet in the hive, they will appear to be very large, because they are well filled with honey, and putting it through the process of digestion—or, more exactly, inversion.

The young queen you found after putting the bees through a "strainer" (perforated zinc) was probably from some cell which you missed.—ED.]

Moths in Comb Honey after it Leaves the Hives

Dr. Miller says, page 36, Jan. 15, "You said moths are liable to lay eggs in S. D. House's combs, or his nice comb honey, after either has been taken from the hives. I supposed his nice comb honey was in sections, so I ventured the guess he never had an egg laid in them after they were taken off, since the moths don't lay eggs in comb honey here after it is taken from the hive. J. E. Crane practically says they do with him. The question now is whether my, moths or Bro. Crane's are the exceptional ones."

I can not answer as to whose moths are the exceptional ones; but if Mr. Crane's are exceptional, so are mine; for nearly all my trouble consists in trying to keep the moths out after the honey is off the hive. In the yard they never bother unless I am so careless as to leave a colony for some time in a weakened condition. But in the house, especially after about the middle of July, it's a fright all the time. Of course it is the larger moth that gives me the trouble in the comb honey, the smaller variety working on old combs alone. But these large moths will get in and lay their eggs all around the wood of the sections, and many times right on the face of the combs.

My only salvation is to use sulphur at least once a week, and even then they sometimes get the better of me in some corner that I have overlooked.

HONEY AS A MEDICINE.

Yes, honey is being used for medicine, and people are not so slow after all in learning to use it and to appreciate it for that purpose. A large number of my customers use it for medicine alone. I attribute it to the fact that, when selling honey through the neighborhood, I have always mentioned in particular that honey is one of the best cough and sore throat remedies known. I often mention, too, that honey is cheaper than butter if used in place of that commodity, and that the food value of it is greater than that of almost any other food. By means of

this and other advertising I number probably two-thirds of the people in this community among my honey customers, although there are several other beekeepers in this vicinity, and some of them sell their extracted honey two cents a pound cheaper than I do.

Barryton, Mich.

LEON C. WHEELER.

The Proportion of Sugar to Water in Nectar

I should like to know how much evaporation is to nectar gathered from clover. We have a hive on the scales that is running in an average of ten pounds a day; but it lightens up a pound and a half each night. Would that be equal to eight pounds and a half a day, or not?

Brook Park, Minn., June 29.

BELL BROS.

[It is not possible to give a definite answer to this question, for the simple reason that so much depends upon general conditions. Some nectars are very much thinner than others, and of course there would have to be more evaporation or ripening in order to reduce it down to a honey that will run between eleven and twelve pounds to the gallon. Ordinary nectar, we should say, would run anywhere from two to ten parts of water to one part of solid saccharine matter. The evaporation that you discover in your hive, where they gather ten pounds per day and lose a pound and a half at night, we should say was very nearly normal. Of course, not all evaporation takes place in twenty-four hours.

It is possible and probable that some of the excess of water is discharged by the bees while on the wing before reaching the hive. You will find some interesting facts bearing upon this subject by referring to *CLEANINGS* for Sept. 1, page 514, and Sept. 15, page 549, 1911. Refer to what is said on the subject of feeding outdoors sweetened water of a sugar of about nine parts water to one of sugar.—ED.]

To Get a Swarm Out of a Box

A drone-trap I bought last year let the queen through every time, and the two last swarms I saved I put the perforated zinc over it. Can you tell me which is the best way to get a swarm out of an old box now? I intend to put the combs in the new hive. I should like to get new queens; but it will be a hard thing to put them in the new hive that I hived this summer, for they build the combs crosswise. I had no foundation.

Ft. Wayne, Ind., June 30. JNO. W. HOEVEL.

[As the queen and drone traps all have standard width of perforation, your letter shows either that the queen in question was abnormally small or else that the trap had been bent or injured in some way, allowing an opening for the queen to get through.

If we were in your place we would treat the hive in which the combs are built crosswise just as though it were a box hive, and drum the bees out according to the plan described in the enclosed circular on transferring bees.—ED.]

When the Giving of Foundation Causes Swarming

I have six colonies of bees; and, although the past winter on Long Island was the coldest we have had for thirty years, my bees came through the winter in better condition than ever before. I did something I never did before—namely, left the entrance wide open and put one super on the top of each hive. The result has been at this date, May 23, that I have had more swarming than ever before. A swarm has issued from each hive, and in some cases two already.

What is the best way for me to prevent swarming? I use the ordinary eight-frame dovetailed hive, and do not think much of it. It seems to me that a Jumbo hive would prevent swarming. I understand that the Dadants do not have swarming, but do not know what they use.

E. GRISWOLD.

Great Neck Station, N. Y., May 23.

[Mr. A. B. Marchant, of Sumatra, Fla., one of the largest honey-producers in the United States, believes that the giving of supers of foundation will start swarming when the giving of supers of *drawn combs* will check it. Beginners will often give section supers to a colony before it is strong enough to enter. This may or may not have a tendency to check swarming; but nothing is accomplished by giving supers too soon. On the other hand, when a weak colony has filled its brood-nest clear full of

honey, the giving of a super of sections will not help much. If the colony is too weak to go into a section super, a better way is to take away the combs that are full, providing they contain no brood, and substitute empty combs. Or this may be done: Give a *s. allow* extracting super of *drawn combs*; but don't expect a weak colony to draw out foundation in sections or shallow frames unless there is a very strong honey flow on, for they will probably sulk just as soon as they get the brood nest full, and then swarm. Before bees will enter a super containing foundation the colony must be strong enough so that the super will be filled with bees. And even a strong colony will refuse to go up unless there is plenty of bottom ventilation, and it may even be necessary to set the hive up on four blocks.

The question whether the hive is eight or ten frame or a jumbo, in your particular case, had nothing to do with swarming, except that the jumbo or ten-frame would have a little more storage capacity, and according as it is larger it would delay swarming.—ED.]

Springs to Hold the Brood-frames Close Together

As I have had a great deal of trouble in reaching the brood-chamber, owing to the fact that the frames have a tendency to spread out and fill up the hive until there is no room to break the first frame loose when cutting it out, I have adopted the following plan: I take two sections, cut them down to the length and width of the spacing part of the frames, and tack them on the hive body so that the frames will come against them, making a full beespace between the top-bar and the body. On the other side I use super springs to press the frames together. I cut the spring long enough to make the pressure half way on the spacing part of the frame. I also equip my shallow supers in the same way.

Ashville, Ala.

W. D. PRICKETT.

[It is seldom or never necessary to use springs to hold brood-frames together; and although springs are very useful in a comb-honey super, we think the more you use the arrangement you describe, the less you will like it. Mr. Danzenbaker provided springs in the brood-chamber of his hive; but in actual practice we do not use springs in the brood-chamber, for we consider them not only unnecessary but too much extra machinery to handle every time the hive is opened.—ED.]

Stock Eat Sweet Clover Down to the Stubble

I noticed on p. 324, May 15, that the stock referred to do not eat sweet clover readily. In this vicinity all kinds of stock eat it down to the ground, and the only trouble is that there is not more of it to be eaten. This, however, is a dry locality, and there is not much natural pasture. The plant does not grow on the high land here, but along creeks and in canyons.

Mohler, Wash., May 25.

To the Discouraged

Come, you discouraged ones; why should you murmur,

Mourning for bees that will gather no more?

Look not at hives that are piled by the corncrib;
Smell not the odor that comes through the door.

Clean up the old hives; of dead bees make compost;
Bury them well in the rich garden soil;

You can replace them by carefully trying—
A little less mourning, a little more toil.

See! the white clover lies thick on the hillside;

Basswoods so budded the branches will bend;
Harvests like this may be often repeated;

Do not be thinking of what might have been.

Gather the combs for a careful assorting;

Melt up the poor ones and care for the rest;

Keep your heart fixed on the main proposition—

Mayhap these losses were all for the best.

One thing is certain; the prices of honey

Now will be better than ever before;

Work, in the future, may bring you more money;

Then work with the vim and the courage of
yore.

Bridgeport, Wis., June 13. HARRY LATHROP.

Our Homes

A. I. Root

CHARACTER BUILDING; SOME SUGGESTIONS TO EMPLOYEES OF THE A. I. ROOT CO.

Seek ye first the kingdom of God, and his righteousness, and all these things shall be added unto you.—MATT. 6:33.

My good friends, I suppose every one of you would be glad to get better pay; and I want to tell you that the A. I. Root Co. would *also* be glad to see you get better pay, and this is why I offer some suggestions. First, I want you to read the following, which I clip from the Chicago *Advance*:

A few years ago a prosperous business corporation applied to a bank president whom we knew, asking him to recommend to the house a young man "who could be trusted." The reply was, "Every Wednesday evening at the hour when the church bells are ringing a young man passes my house on his way to the prayer-meeting of his church. I like that. If I were you I would look him up." And the business man did look him up, and made him an offer of double the salary he had been receiving—and he is now getting more than he had ever dreamed of. We know the parties, and knew of the incident at the time. The prayer-meeting habit is a valuable business asset—better in some respects than a college diploma. Another incident came to our knowledge in regard to the week-night service. One of our city pastors recently went into the wholesale section of the city and asked to see one of his "boys." "Have we any of your church members here?" said the manager. "Yes, six." "Are any of them Christian Endeavorers?" "Four." "How many go to the Wednesday night prayer-meeting?" "One." The next morning that "one" was sent to a distant State upon an errand calculated to test his honesty, ability, and zeal. On his return, having successfully performed his duty, his opportunities were enlarged and his salary quadrupled. The prayer-meeting habit is a good asset; but the Sunday-baseball passion will cost any young employee dear. We know a bank president in the West who dismissed a clerk for attending the races upon a track in which the president was himself a stockholder. The business man is made or marred usually before he is twenty-five.

The above is a fair illustration of the way in which clean straight young men often get an advance in wages. I do not by any means recommend that you should go to prayer-meeting or Sunday-school, nor even to church, solely with the idea of getting *better pay*; but a consideration of the matter may prove to be at least one incentive. The habit of these young men had built up character; and this world needs clean men and boys more just now than ever before.

Now, in order to get back to what I have had in mind for some time past, will you excuse me if I mention that, when the whistle blows at quitting time, quite a number of our employees get out their pipes and tobacco just as soon as they are off our premises? There is a very good reason, that I need not mention, why it would be unwise to have smoking of any sort around the combustible material that most of you

work with. From the clipping I have given you; you will see how a small matter fixed the wage value of a man or boy. Really, do you think *any* institution would pay *more* for the boy who lights a pipe every day when he starts home for dinner? Would not almost any employer of men decide against the boy who smokes a pipe?

Our State of Ohio has passed stringent laws, as you may know, against selling or furnishing tobacco to boys; and it is now pretty well known that boys who are ambitious to excel in physical strength have cut off their tobacco, or else never used it. Our schools and colleges not only give us abundant evidence of the effect that tobacco has on the intellect, but I believe it is generally conceded that tobacco in any form is a stepping-stone to stronger stimulants.

What has particularly called my attention to this matter just now, is the statement that a boy in our employ recently took his pipe out of his mouth and went around to other boys, big and little, and urged them to "take a pull" at his pipe—the pipe he had just taken out of his tobacco-stained and dirty mouth! Now, most of you know (better than I do) how much truth there is in it, and it prompts me to appeal to your best and most manly sentiments in regard to the matter. I think, if you will look about you, you will find that as a rule our leading men who occupy high and important places are not tobacco-users. Abraham Lincoln never used tobacco. Roosevelt does not use it in any shape or manner; neither does Bryan, and it is very unlikely that either of them ever will use it.

When we recently installed convenient and pleasant closets for men in our different buildings, a kind request was posted up, not to spit tobacco juice on the floor nor in the corners of the room. Notwithstanding this, it has pained me to see the disagreeable accumulation, little by little, more or less, in every one of our men's closets.

Let me ask in closing, dear friends (for I hope you are all my friends), will you not consider the matter, and help your employers in their efforts to keep up the reputation our establishment has long enjoyed, for not only being up to date in every sense of the word, but for setting an example of cleanliness and decency?

I have given you in the above a word-picture of two boys—one on his way to

prayer-meeting, which he attends regularly, and probably *invites others* to come with him. The other boy goes along the street puffing a pipe. He is not going to prayer-meeting, however, you may be sure; but he takes his pipe out of his mouth, and also "invites others" to take a pull on it. Which of the two boys will have the better chance, and get the best pay for his services here in this world? And, finally, when he comes to die, what then?

There is no man that hath left house or parents or brethren or wife or children, for the kingdom of God's sake, who shall not receive manifold more in this present time, and in the world to come life everlasting.—LUKE 18:29, 30.

The above was printed on a leaflet, and one of these leaflets was put into the pay envelope of each one of our between 200 and 300 employes when they got their pay on Saturday noon. We hope and pray that it may bear good fruit. While we are on the subject of tobacco I wish to submit to you a clipping from the *Sunday School Times*:

WHAT IS TOBACCO?

In the terms of the physician, and told in brief, tobacco is purely and simply a poisonous drug, having no beneficial influence, and for this reason removed from the authorized list of medicaments in which it once had room. It has no food value, it is a narcotic similar to opium in many of its features, its use seldom fails to constitute a drug habit.

Now, you who use tobacco, and everybody else whose eyes rest on these pages, I submit the question: Is it not true, as stated above, that tobacco is not food and is not medicine? It is simply a poisonous drug, and probably forms the worst drug habit that has ever afflicted humanity if we except intoxicating liquors; and how many ever began the use of liquor without first using tobacco as a stepping-stone?

Here is another clipping, from the *Cleveland Plain Dealer*:

GAINS 300 SALOONS.

H. H. Schleman, in charge of the liquor-tax collections in the county treasurer's office, said yesterday that 300 more saloons are doing business in Cleveland than last year.

Licenses have been issued to 905 cigar dealers—an increase of more than 100 over last year.

What do you think of the above? There may be differences of opinion in regard to whisky and tobacco; but I am sure there is a pretty general agreement in regard to cigarettes; yet the above clipping informs us that the city of Cleveland and the State of Ohio grant licenses to sell the deadly "coffin-nails;" and not only that, during the last year one hundred new licenses have been granted. "Lord, help!"

Now, lest you take it for granted that I am a "calamity-howler," and hunting up all the sad and mournful things, let me give you another clipping from the *Sunday School Times*. Perhaps I should explain

first, that over in "Merrie England" it used to be the fashion for the mother of the home to carry the purse; and I wonder if it would not be a good fashion to adopt here right now in our "land of the free and the home of the brave." Well, this clipping that I am giving you is English, as you will notice by the talk; and I am sure it will interest our people who love poultry as well as temperance. Read it yourself and see if I am not right about it:

THE EX-MISERABLE'S BEER MONEY.

Mr. Harold Begbie tells the following in *The Century Magazine*: I was introduced a few months ago to a painter by trade, an ex-fighting man, an ex-drunkard, an ex-miserable. Religion has restored his soul, given him new birth, and made him a useful citizen. He told me how his mates "get at him" for being a teetotaler, and how they are continually asking him, "Don't your missus ever give you any beer money?" "To which I answer them," he said, grinning, "Hoh, yuss; my old lady gives me plenty of beer money—shillings and shillings. And where do you think I keep it? In my garden. Ain't that artful of me? And some of my beer money has got feathers and lays eggs, and some has got fur and makes lovely pie, and some has got flowers and smells a bit of all right. Yuss, if you'd like to see my beer money, drop in some Saturday afternoon and take a walk round my garden. I'll show you last week's beer money, the week's before—yuss, and last year's—hopping and clucking and crowing and smelling beautiful. By the way, old friend, where's *your* beer money? Where is it? Can you show it to me, or is the publican keeping it for you till Christmas?"

Now here is just one more clipping, which I take from the *Union Signal*, that makes me happy every time I think of it. Read it:

GOVERNOR WEST'S CAMPAIGN OF LAW ENFORCEMENT TO SAVE THE SONS AND DAUGHTERS; OREGON'S CHIEF EXECUTIVE CALLS OUT MILITIA.

"Hasn't the governor authority to use the power placed in his hands to protect the God-given property of some poor helpless mother or father? I think so. Anyway, I know one governor who is going to put the question to the test mighty soon," announces Governor West.

Probably no State has ever been more surprised at the act of its chief executive than were the citizens of Oregon when Governor West announced his campaign of law enforcement, which he stated he would carry out through regular channels if his warnings were promptly heeded; otherwise by invoking martial law, with himself as commander-in-chief. He declared that his efforts would be largely directed toward the saloons and road houses, and that the shipment of liquor into dry territory must be stopped at once.* A few days after the issuance of this warning through the press, the platform, and the pulpits (the latter have been freely opened to him) he called a meeting of the saloon-keepers and brewers, to whom he planned to deliver his warning and ultimatum. Because of the absence of the manager of the biggest brewery, the liquor men sent him word that they greatly desired a postponement of the meeting, doubtless hoping that the Governor's action would also be deferred. Evidently, however,

* Once more may God be praised that we have at least one governor who realizes not only the harm but the awful inconsistency of permitting brewers and distillers to continue to ship liquors into territory made dry by the wishes of the people. Manatee Co., Fla., has never had a saloon; and the good people there, I think, will never permit one; but liquors are being shipped in by express constantly, despite any thing we can do; and these shipments go mostly to the colored people. Only a few days ago for the first time that any thing of the kind had occurred in that part of Florida, a negro was taken out of jail and lynched, when it was not quite

this meeting was considered by him only an incident in his campaign, and on the day set for its opening he fired the first gun.

Among a number of roadhouses that are to be reached on the various drives from the city (all of which have been a serious menace to the morals of the city for years, not only in encouraging drunkenness but as links in the white-slave chain) was the Milwaukee Inn. Many attempts have been made to close this place, or at least to mitigate its evils; but as it is beyond the corporate limits of the city, and just across the county line, it is out of the jurisdiction of both the city and county officials: and as Portland and Multnomah Co. were the chief sufferers, the officers of the county in which the house was located, after the manner of some officials, preserved themselves in peace and official blindness.

At ten o'clock on the morning of the day which our young Governor had announced as the opening of the war, he appeared at the Milwaukee Inn, with a company of about fifty carefully picked men of the Oregon militia; and after reading a military proclamation to the proprietor, reciting in clearcut language the unlawful character of the place, warning all persons against frequenting it, he took charge of the establishment. There was placed at

clear that he was guilty of *any thing*. The sheriff was on hand, but he declared himself helpless. Without question it was the work of *liquors*, shipped in to dry territory.

the gates a guard sufficiently large to enforce the martial order which was affixed to the door. Governor West states it is his fixed purpose to proceed against other roadhouses and liquor concerns, saying "I do not care who is responsible for conditions; they have got to obey the law. It makes no difference whether it hits the big breweries or the lessees; they have got to be good, or they will see their finish before I get through with them."

Being questioned recently as to his right to invoke martial law, he replied that no one doubted his right to call out the militia to protect property against lawlessness, and he considered the children of the State as valuable assets as houses and stocks, and he proposed to test his right to give them the protection derelict officers had failed to give. What the next move will be one can not tell; but our governor is aroused; he is made of stern stuff; he will have the support of good men and women, and, so far as we can decide, he has the law on his side. It is needless to say we will keep *The Union Signal* informed as to the progress of this war.

May the Lord be praised that we have at least *one* governor who is not a *coward*, and afraid of the liquor men. If we could have this man or such a man for President of the United States I should begin to think the millennium was at hand.

Health Notes

FERMENTED MILK; ALSO SOMETHING IN REGARD TO MILK AS A HEALTHFUL FOOD.

A good friend of GLEANINGS has placed in my hands a pamphlet of 30 pages, from the Department of Agriculture, entitled "Fermented Milk." It discusses buttermilk, lactose, yoghurt, kumiss, kefir, etc. It is well known that the people of Russia, Turkey, and other northern European countries, have for ages lived largely on fermented milk. Many of those who live to be a hundred years old or more have been in the habit of subsisting largely on various preparations in the line of fermented milk.

There are many valuable hints and suggestions in this bulletin; and I am glad to know that public attention here in our country is turned toward having buttermilk and various other productions from milk take the place of beer and other intoxicating liquors. God speed the day when good nourishing health-giving milk shall take the place of intoxicants.

This pamphlet calls attention to the fact that it is not every one who can use milk largely; and many people at times find it better to cut off milk for a time. That has been my case for years. After drinking milk freely at meals for a month or two I often find it does not agree with me; but after a spell I can take it again all right. I believe there is a general agreement, too, that buttermilk or fermented milk in some form is more wholesome, as a rule, at least with many people, than rich fresh milk. I wish to emphasize one thing that is very

clear and plain to me; and I think the same will be true with most people. Neither milk, ice cream, nor any thing else, should be taken between meals. Even a little fruit in hot weather, while all right during meal time, makes disturbance if taken between meals. When you feel a hankering for fruit, especially during these hot summer days, drink a good lot of soft pure water and you will soon forget the craving for fruit; it is very much better for *me* to eat all my fruit at the time of my "fruit supper," about five in the afternoon. At this time I eat all the fruit I care for, of various kinds, and it causes no disturbance whatever. Nature seems to have caught on to the program, and plans regularly for it day after day. Of course, no milk is used with my fruit. I take the milk in the morning and at noon.

After the above was in type we received the following from the friend who sent us the pamphlet mentioned:

It seems to me that in your list of simple foods which you recommend there is one or perhaps two that might very appropriately be added. One of these is the old-fashioned "clabber" of our grandparents. This, when well made from pure unskimmed milk, and thoroughly cooled, makes as refreshing and wholesome a dish as one bent on simple living could well ask for. To be sure, individual tastes differ, and what may be acceptable to one may not meet the requirements of another. While there is little doubt that clabber rightly made is a very good thing for those who relish it, it would be hard to conceive of any thing much more dangerous than the product one would get by attempting to make it with contaminated milk. It is, therefore, very necessary to know at the start that the milk is pure. It should also be borne in mind that acid fruits, apples, cherries, etc., are things to be omitted at the time curdled milk is eaten.

Another wholesome and simple food is the curd obtained by using rennet, and flavored to suit one's liking. Often this will be relished by those who can not take the soured curd.

May be I should add that, in making the clabber, the milk is first brought to the scalding-point, but not allowed to boil. It is then cooled to about 90 degrees F., and the starter is added. The milk is then kept warm until the curd has formed. It should then be immediately cooled, when it is ready for use. The starter may be obtained by using a small quantity of fresh skimmed milk (half a pint). This must also be scalded, and allowed to cool and sour. Whole milk makes the most palatable clabber; but the starter should contain as little cream as possible.

I trust you will not overlook the importance of mentioning the fact that fermented milk and fruits taken at the same time may bring about serious digestive disturbance with some people.

Aikin, Md., July 13. J. FORD SEMPERS.

NOSTRUMS AND QUACKERY.

On page 19 of the advertising department of our previous issue I spoke of fraudulent medicines. Well, this same medical association has placed in my hands several pamphlets exposing fake cures for drunkenness, the tobacco habit, obesity, consumption, etc. It is bad enough to "rob sick people" in general; but when you come to robbing the drunkard or drunkard's wife by systematic robbery, how can one well find words to express his disgust and indignation? I have for some time been suspicious of these "cures" for the rum and tobacco habit; and several of our readers who have followed them up have written us the results. If the tablets that are sent free of charge have any effect on the poor victim of tobacco or drink it is by giving him morphine, cocaine, or some other habit-forming drug that is worse, if possible, than tobacco or alcohol. Most of these schemes are advertised by some good woman(?) whose husband or brother or other relative has been cured. She pays the expense of advertising out of her love for humanity, and tells people who respond to her advertisement to send to some great doctor in Chicago. The thing is skillfully worked up so as to entrap the friends of the poor victim, and get them to scrape up their hard earnings to send to the "great medicine man." The cure for obesity is \$25.00; but, like the memory school I have mentioned, if the victim does not "bite" they come down to \$15.00; a little later to \$10.00, and finally you can get the whole thing for \$2.00—that is, if you hold back and do not bite right away. These quacks, as you will notice, make a specialty of curing diseases that are beyond the skill of our best doctors—cancers, consumption, epilepsy, etc. I am sorry to know that these rascals are usually punished by fines only, which they can generally pay and go on with their swindling. If our health commission would add imprisonment, and give

them a good long term, it would cure *them*, for a time at least, of *their* pernicious habits of robbing sick people.

Just a word in regard to the medicines sent free of charge. As a matter of course, these give temporary relief. Cocaine, morphine, or a headache cure usually makes you feel better; but for that matter so does a little whisky; but who would think of resorting to whisky every time he feels bad? or who would expect any permanent relief from such a course? When you are cured of any of these troubles by letting nature do the work, as *Terry* directs, then you have accomplished something; but I confess I am gradually coming over to the decision that medicines and the stuffs you buy at the drugstores seldom really *cure* any thing.

ROBBING SICK PEOPLE; "OXYPATHY" AS A REMEDY FOR DIABETES, PARALYSIS, ETC.

Mr. A. I. Root:—I thank you with all my heart, my Christian friend, for the advice you so kindly gave in regard to my husband's health (you may remember my writing to you in Florida about his sufferings from diabetes); and I feel sure that our prayers have been heard and answered, for he has been able to work right along, and at least seems to be holding his own. Circumstances have, however, been such that I could not keep him strictly to the diet you advised. His mother was lately restored to health (as she believes) from a threatened attack of paralysis by use of an "oxypathor," and she thinks it is the veritable cure-all it is claimed to be. I offered to give them a 60-day note (with the money deposited in a local bank) for their instrument, with the understanding that, if my husband's health improved while using their instrument, they could collect the money; if not, we'd return their oxypathor and stop payment of note. They didn't send one on those terms. So I was afraid to invest. As your experience and skill in detecting frauds is far greater than mine, I enclose some of their advertising matter for your inspection, if you have time, and would greatly appreciate your opinion as to the worth of this (to me) new contrivance.

FANNIE M. FEREBEE.

Ridgeland, S. C., July 5.

My good friend, I am glad you wrote me before wasting your money on what you call a "new contrivance." On the contrary, GLEANINGS has been fighting this same fraud for more than twenty years. See last issue. I notice by the circulars you send, that, instead of the old price of \$25.00, they have now got it to \$35.00, when 35 cents ought to pay for the whole outfit if it were of any real benefit to anybody.

Let me remind you of another thing besides wasting money and "robbing sick people." Some years ago our good friend Prof. Cook informed me that his father lost his life by depending on patent-medicine quackery. He was afflicted with a malady that could easily have been managed if taken in time; but instead of going to a physician (or to his *own son*) he trifled with some senseless remedy until he was past help. Most sick people are better at times; and if these times of improvement

happen after they have taken some patent medicine, or "treatment" of some sort they jump to the conclusion that it was the senseless toy that conferred the benefit, and hence these testimonials—that is, testimonials that are not really manufactured. Years ago electropoise, oxydonor, etc., claimed to have "testimonials" from one hundred ministers. The thing has gone down and out of sight several times, only to be resurrected (perhaps under a new name) by some conscienceless rascal or set of rascals.

SOMETHING ABOUT DR. TANNER; FASTING AS WELL AS BEE-STINGS AS A CURE FOR RHEUMATISM.

Mr. A. I. Root:—In GLEANINGS for Feb. 1 a correspondent asks about stings as a cure for rheumatism, and says he is "ready for something heroic." As you always have a corner for unfortunates in Home talks, perhaps you will publish the enclosed for his benefit, as well as for others who may be afflicted.

Dr. Tanner was lecturing in 1903 on the benefits of a vegetarian diet, which he advocated. One lecture was "The Story of the Fast," delivered in Blanchard Hall, Los Angeles, California. I wish I could give the whole of that most interesting and amusing story. Young people, and even the middle-aged, are strangely ignorant of this feat that once filled the civilized world with wonder. They even say coolly that it was not proved he ate nothing in all that time. There are a few left who know. Perhaps you could tell us more about the doctor.

The following is condensed from a lecture by Dr. Tanner:

The doctor was practicing in a town in Ohio about 1870. He was disabled by rheumatism in 1875. Then he went to Minnesota, where he had a friend who was also a physician. This man told him that his heart was in a very bad shape—it might stop beating at any moment. He had pain in the region of the heart—could not lie down.

Tanner went home, very much cast down by his sentence. He sat down in his chair, and paid no heed to any thing. He was not ready to die. He had no thought of food. At the end of five days he accidentally discovered that he could lie down.

The thought came instantly that improvement came from fasting. He then fasted six days more. He felt better, and went to see his doctor, who was very much astonished. "Why, man," said he, "you are cured. Your heart is all right. What have you done?" The cure astonished him still more. Said he, "Ten days is the limit. You have fasted eleven days."

But Dr. Tanner thought the cure might not be permanent. He went home, staying alone in his rooms, and went on fasting, until it was forty-two days.

He went again to see his doctor, and told him. The amazed man was for doing something immediately. "This," said he, "must be sent to the medical journal."

"No," said Dr. Tanner, "you must not publish that. People would not believe it."

The friend respected his wish, but told another doctor, who, without permission, published the case in a medical journal.

"Then," said Tanner, "I was made to suffer. I was told even to my face that I had lied." (He was then selling real estate in Minnesota). "My customers left me, and church members turned their faces away." But there was one consolation. "I have never had rheumatism since," said the doctor.

A year or two later (in 1877) a New York paper came out with a story of a young lady who, in a trance state, had fasted several weeks. (I can not recall how long. Doctors discussed the subject, many saying it could not be true. Dr. Tanner offered to come to New York and fast, under surveillance, forty days, for one thousand dollars. This was offered by Dr. Hamilton at the Medical College.

After a while it was arranged, and Dr. Tanner went to New York and made his famous fast.

LOUISE S. Z. BEMIS.

Cattaraugus, N. Y., Feb. 8.

My good friend, Dr. Tanner, was a *Medina Co.* boy, and he was back to his Medina home several times before he died. There is no question in regard to the authenticity of his statements, and I believe he really was the first man living to demonstrate that some people can actually live "forty days" without food. Since then many people have taken it up, and, I think, generally with benefit, although a very few who are, perhaps, not fitted for such experiments, have been injured by fasting. I believe one person lost his life that way. In our back numbers there have been many reports in regard to it. Upton Sinclair is at present, or at least was until quite recently, the strongest exponent and defender. The periodical *Good Health* for May condemns it in the strongest terms. But they may be extreme in this as well as in some other things. I have frequently gone without food for 24 hours, and I am ready to do it again when nature seems to demand it. I have not yet tried a longer fast. I have not a doubt that it would cure rheumatism and, in fact, almost anything else, if the patient has the grit and backbone to avoid declaring "the remedy worse than the disease."

BETTER THAN FINDING A GOLD-MINE.

We take pleasure in giving place to the following, clipped from the *Practical Farmer*, inasmuch as it comes from a beekeeper and a reader of GLEANINGS:

IF YOU ARE NOT ENTIRELY WELL, PLEASE READ THIS.

A certain doctor said to the writer: "Terry, why do you confine yourself so closely to your study and work so hard? You don't need to; you have property enough. Why not make your life easier now?" My good friends, do you want to know why I do not follow his advice? Then please read the following letter. What is my pleasure, or my little life, worth by the side of being helpful in thousands of homes scattered all over America? This is from Joseph H. Peterson, Ogden, Utah: "I am a beekeeper, and received your book about 18 months ago as a premium with GLEANINGS. Then I subscribed for *The Practical Farmer*. To me this was better than finding a gold-mine. I am 34 years of age, and had suffered for years with chronic constipation and attendant ills, such as stomach trouble, piles, and countless wretched headaches. I ran the course of pills and laxatives, and was taking regularly two injections daily when I got your book. And even if the doctor did tell me I would have to take physic the rest of my life, I now have two and three natural bowel movements daily. Of course, my other ills are going too. Even my threatened baldness is being frustrated since I learned how to live. I am happy to be on the highway of health again. The sun shines brighter, the birds sing sweeter, and my blighted hopes are budding out again, as does all nature at the return of spring. I was ill in body, dejected in spirits, and while I had not lost hope, I was fast letting go my hold on the things and ambitions of life. But I thank you for making plain the simple laws of health, for now I can renew my hopes and ambitions and feel again the vigor of youth and sing with a thankful heart, "Praise God, from whom all blessings flow." No living man

could write such words unless he had pure blood coursing through his arteries once more, and was feeling the thrill of joyous health. With such health it is a real pleasure to breathe, eat, sleep, work. We greatly like the tone of this letter. The writer thanks us for making plain the simple laws of health, which is all we can do, and praises God from whom all blessing flow. How true, "He healeth all our diseases" through his natural agencies of air, water, sleep, food, exercise, etc. We thank friend Peterson most heartily for the trouble he took in sending this report. It certainly will be helpful to some who read it. And we feel under deep obligations to The A. I. Root Co., publishers of GLEANINGS IN BEE CULTURE. They are spreading our efforts far and wide. May it prove "better than finding a gold-mine" to every one of their readers.

If our friend Terry had something to *sell* we might take such extravagant words with a grain of salt; but, may the Lord be praised, he does not advise any medicine whatever—simply nature's agencies, as he expresses it, which are as free as the air we breathe.

POKEWEED FOR GREENS—SEE P. 389,
JUNE 15.

A subscriber sends us the following:

TWO GIRLS DIE OF POISONING.

Miss Lavie Henshaw, 16 years old, and Miss Sallie Pierce, 14 years old, died at Durwood, Ok., May 12, after they had eaten wild greens that contained leaves of the poke plant.

Three other members of the Henshaw family were stricken, but are recovering.—*St. Louis Republic*.

Now, it may be that pokeweed is poisonous, especially if cut down close to the root; but I am loath to believe it. Did not those girls, in their search for "wild greens," get hold of some other plant that was poisonous? From the quantity we gathered at different times down in our Florida home, without the least unpleasant symptom, however, after eating it, I can hardly understand it, unless there is some other plant that goes by the same name. At any rate, it is always wise to take a little at first of something you are not used to, or not very well acquainted with. This is especially true in gathering mushrooms as well as plants for "greens."

CHUFAS.

On page 388, June 15, I spoke about writing to Mr. Hastings in regard to the statement of growing 1000 bushels of chufas to the acre. Below is his reply in regard to the matter:

Mr. A. I. Root:—We have your favor making inquiry as to chufas, and would say that the writer can not give the exact data from which this 1000-bushel figure came; but he is under the impression that it was a test yield with one of the Southern experiment stations several years ago. The statement has been current in Southern seed catalogs for years, but the origin of it is lost. We are aware that 1000 bushels per acre of chufas would be an enormous yield, but we do not consider it an impossibility. There have been yields of potatoes approximating 1000 bushels to the acre, and the writer has personal knowledge of one crop of onions in Texas some five or six years ago that went slightly over 1000 bushels by weight; and under an intensive system of culture there is no reason why chufas should not make an equally high yield.

Atlanta, Ga., June 6.

H. G. HASTINGS.

As the above makes reference to the Southern experiment stations I have written our Florida station to learn if they have tested chufas. I presume there *have* been yields of potatoes (on small areas) approaching 1000 bushels per acre; but contrast the difference, please, between potatoes and chufas. In order to get any thing like this result the chufas would have to be 15 inches apart in rows 2 feet apart, and each plant would have to give at least two quarts of nuts.

CHUFAS AS A SUBSTITUTE FOR COFFEE.

Now, after finding so much fault I have something pleasant to tell our readers—at least those who have been testing chufas. A periodical published in the Everglades, in telling the wonderful things that can be grown there, mentioned chufas; and, while they are very valuable for pigs, poultry, food, etc., it is stated they make excellent *coffee*. I at once ground up some roasted chufas in a coffee-mill—the kind I have written about. I would remark here that they were baked or roasted in the oven, and it was one of my happy surprises when I tasted that chufa coffee. Huber happened to come in at the time, and we gave him a cup to sample. His first exclamation was that it tasted like *malting milk*. Now, malted milk is one of the staple foods for invalids or anybody who has weak digestion; but it is rather expensive.

Just here let us consider the point that vegetarians (and among them our good friend T. B. Terry) have been for some time suggesting that nuts are an excellent substitute for meat or animal food; and right here we have it—a substitute for milk that is *entirely* vegetable, and I am sure it must be nourishing, and it certainly will be far cheaper than any sort of stimulating nerve-racking real coffee—even cheaper than "postum cereal;" and if we could raise 100 bushels to the acre (to say nothing of 1000), it would be cheaper than Terry's wheat coffee. The chufas should be roasted just about as you would peanuts, may be a little more, and then grind them in a coffee-mill, and use one or two heaping tablespoonfuls, say for five or six cups of coffee.

Later.—Here is something from the Florida Experiment Station in regard to chufas:

Dear Mr. Root:—We have grown chufas from time to time at the Florida Experiment Station, and do not consider them the best thing possible for hog feed or for cropping purposes. I think the claim of one thousand bushels an acre for chufas is entirely unreasonable. I did not see Hastings' statement to this effect.

We should be very glad to raise 100 bushels per acre on the average. As a matter of fact, very few farmers in Florida claim more than 75 or 80. Once in a while we hear a man claiming to raise a hundred bushels or over; but these are farmers who

have made a bare estimate on what the crop would be if it were all like a portion of an acre that they have dug.

Some newspaper articles have been going the rounds giving a yield of something like two hundred bushels of chufas to the acre. I can not say just how these results were obtained, as it is quite impossible to follow up even a small percentage of these reports of extremely large yields.

So far as the printed matter from the Florida Experiment Station is concerned, it has been extremely mute on the question of chufas. I can not understand, therefore, to what Mr. Hastings referred when he states that they are highly recommended by the Florida Experiment Station.

Gainesville, Fla., June 15. P. H. ROLFS.

Well, friends, how does the above compare with Hastings' advertisement in his catalog and in our farm papers, of 1000 bushels per acre? By the way, would it not be a grand plan if our different experiment stations would scan the seed catalogs each year, and call down extravagant and misleading advertisements? See page 388, June 15.

REDBUGS; MORE ABOUT THEM.

I saw an article in GLEANINGS (p. 769, Dec. 15) on redbugs that is overdone. I have lived in Ohio, Illinois, and now in Texas nearly four years, and redbugs are not everywhere in Texas; and I think likely it is a mistake that they rear any offspring in flesh. Grease helps somewhat, but often fails completely to be of any benefit whatever; but if you use grease beforehand, all right.

I know several native Texans who are just as susceptible as myself to redbugs, poison oak, cowage, and vine poison. I am immune just so long as I stay away from them. Some people have an idea that Texas is what Sheridan said war was, which is a mistaken idea.

Bloomington, Texas, Dec. 26. L. A. CAMERON.

I think very likely the above is correct. During the past winter we were so free from any annoyance from redbugs and other insects that I was inclined to think they were disappearing or that we were becoming immune; but along in March and April, after the rains had ceased that we had been having quite freely all winter, the redbugs came back, and I think they were about as bad as I ever saw them. A few days ago I happened to ask my neighbor Rood if they were troubled with redbugs. He replied that they had not been troubled at all, and added that, if we would clear off the scrub palmetto from our ground, as he had from his whole farm, we would have no more redbugs. I think this is probably true; but in caring for my ducks and chickens it is almost impossible for me to keep from brushing the palmettos more or less. And, by the way, I am greatly inclined to think that the greatest part of our troubles are from poisonous vegetation such as the writer mentions in the above. I am sure it is true, because I have had at times a breaking-out that nearly covers my body, something like what we used to call "hives" here in the North, during hot summer weather. Redbugs are bad enough; but I do not believe they are the cause of all this breaking-out and itching. The lady writer

in our issue of Dec. 15, referred to, thinks that, when these bugs get a foothold, they may remain for two weeks. This, certainly, is a mistake, I think; for when we come back North all annoyance ceases in two or three days. It is a week to-day (April 23) since I left Florida, and I can say that almost all traces of redbugs have disappeared entirely. Perhaps I should add that people who live in towns and do not go out into the woods are seldom troubled with any of these pests.

SELLING RECIPES FOR DOING THINGS, ETC.

One of our subscribers sends us the advertisement below, which he clipped from the *Mississippi Commercial Appeal*:

Send \$1.00 to-day for recipe to make gallon good honey for 50c without bees. May not appear again. W. J. Green, Rienzi, Miss.

Of course we have wasted many dollars in times past in sending for recipes; but here goes one more.

After five days comes the recipe as follows:

One and a half pounds of bees' honey; six pounds light brown sugar; one and a half pints water; two ounces cream of tartar.

Dissolve cream of tartar in a little water, then put all articles together and boil in a copper vessel until well mixed, usually twelve to fifteen minutes; stir while boiling; skim off froth that arises while boiling, which eats well. Now ready for use, but improves with age.

Can make again, using what you have made instead of honey.

Here is the letter accompanying it:

Mr. Root:—Your letter containing \$1.00 came to hand, and is duly noted. Enclosed find receipt for making one gallon honey without bees. You will make as nice honey as you ever eat. The longer it stands, that is, the older it gets—the better it is.

Thanking you for the order, I am yours truly,
Rienzi, Miss., May 15. W. J. GREEN.

In the first place, it is practically the same old recipe that was in the papers at least forty years ago. Second, he claims to make honey without bees, and yet it takes a pretty good dose of bees' honey to make the stuff. We are glad that such things now are not as common as they used to be; but I am going to submit this whole matter to the proper authorities, and ask them if this man is not making a fraudulent use of the mails.

PARCELS POST CHEAPER TO FOREIGN COUNTRIES THAN TO OUR NEXT-DOOR NEIGHBORS.

I clip the following from the *Rural New-Yorker*; and after you have read it I hope you will do something more than to "think and think and think."

Going through the busy corridors of the New York postoffice one sees a placard announcing in large black letters, "Parcels post to foreign countries, 12 cents a pound." And then the meek American citizen affixes 16 cents to a pound of merchandise for transmission through domestic mails, and thinks and thinks and thinks!

POULTRY DEPARTMENT

WHITE ORPINGTONS—A REPORT FROM SEVEN PULLETS.

Dear Brother Root:—I am inclosing a record of my first pen of White Orpingtons. I think it is not very far behind the best; but I should be pleased to see your comment on it, if you can conscientiously do so.

At the time these pullets were commencing to lay, it was from 20 to 24 degrees below zero. In January I received 97 eggs from the five oldest. I intend to make egg-production a study and a business. White Orpingtons—number of eggs laid:

Hatched		At 1 yr. old	To July 14, 1912	1st egg laid
5-26-1911	Queen,	65	89	12-27-11
"	*Edina,	109	139	1-4-12
"	Diana,	71	89	1-5-12
"	Mamie	61	80	1-6-12
"	Juliette,	60	82	1-9-12
6-26-11	Red Wing	55	57	1-30-12
"	*Beauty,	123	132	1-30-12
"	*Annabel,	105	119	1-31-12
"	Bunch,	40	52	1-11-12
Total		.689	839	
	*Edina, Beauty, Annabel,	337	390	

These last are the three best layers in the above record. Edina and Beauty never went to sitting until June 26, and Annabel July 14. Beauty missed only one day, May 8, from April 23 to May 22 inclusive.

Juliette became crop-bound, and was sick two months. The other five hatched out two settings of eggs each.

Brunswick, Mo., July 15.

FRANK SMUTZ.

We have given the above, not because there is any thing particularly remarkable about it, but rather because our friend had his pullets all named; and he knows just when each pullet commenced to lay and how many eggs she laid up to a given time. I suppose that the seven were trap-nested, although he does not say so. The whole seven commenced laying when about six months old, and during a time of severe zero weather. I rather think this lot did better, because they had extra care and attention. Each one having a name would indicate it. Now a point comes in right here: Shall this friend save his eggs from the best pullet? I believe the general tendency is, from the best authority, to say no; but instead of taking eggs from the best layers, get the eggs from the *mother* of this great layer. If the mother produced one Edina layer she could probably produce more. This same thing applies to bee culture—rear queens from the *mother* of the queen whose bees gave a great crop of honey, rather than from the queen herself. And this mode of procedure indicates *why* we can pay a big price for tested breeders, either queen bees or mother hens. One thing more:

When you get hold of a fowl that has given you pullets with big records, you should keep that fowl for a breeder, no

matter how old she is. Even if she is so old that she lays only a few eggs, if these eggs have proven season after season to produce pullets that are great layers, hold on to her.

TESTING EGGS BEFORE THEY ARE PUT INTO AN INCUBATOR, ETC.

We clip the following from an editorial in *Poultry Topics* for July:

By testing the eggs before placing them under the hen in the incubator, the farmer can increase the percentage of eggs hatched. In many cases this percentage can almost be doubled.

We have usually found *Poultry Topics* to be a very steady and reliable journal; but the above perplexes me exceedingly; and the more I study it the more I am troubled about it—first, has the editor of *Poultry Topics* been in the habit of keeping a *hen* in his incubator? second, does he mean to tell us that “the farmer” or anybody else, for that matter, can sort out the unfertile eggs before giving them, say three days or more, to a sitting hen, or placing them in an incubator? I know there are at least two persons who have advertised in the poultry journals that they could teach how to sort out the unfertile eggs *before* giving them either to the hen or to the incubator. If I am correct, the magic egg-tester makes some such claim; but I am ready to pay \$100 for any process that will succeed as above at any experiment station. The egg-tester simply gives the specific gravity of the egg; and they claim the heaviest eggs hatch the best chickens. Now, even if this is true, the specific gravity of an egg has nothing to do with its being fertile or unfertile. This I have tested to my satisfaction.

A KIND WORD FROM ONE OF OUR MISSIONARIES.

Mr. A. I. Root:—Time has again brought around one pleasant duty of the moment, which is to thank you, as senior partner in your firm, for your continued kindness to me in the matter of sending me GLEANINGS for the past 12 months, and which is as much appreciated as it ever was.

The swing of the pendulum, I observe, has occurred in your country, and some State legislation has taken place not promotive of temperance. It was the effect I was fearing. Great success in big movements seems always to be followed by some setback; yet the movement is not overthrown.

In this little island, drunkenness is not in fashion, and one may live and move about in it for months without seeing a person the worse for liquor except at such times as fleets visit us, when it seems to me *English marines* take a disgraceful first among the nations represented.

Trusting that many years of usefulness may lie before you in God's cause, and with my best wishes to you and Mrs. Root for a happy 1912, I remain,

W. A. HUTCHINSON.

St. Joseph's Rectory, Barbados, W. I., Dec. 30.

VOL. XL

AUGUST 15, 1912

NO. 16

Editorial

OUR cover picture for this issue represents a field of buckwheat in full bloom, the flowers in the foreground standing out remarkably sharp and clear. In localities where only occasional fields are grown, this plant may not make much difference in the surplus honey crop; but it is often of great value in stimulating brood-rearing or helping to supply winter stores.

CROP REPORTS.

IN the way of crop reports and market conditions, the reader is referred to pages 509-512 of this issue. In the meantime we shall be glad to have our subscribers continue sending in their reports. Make them brief, so that we can publish them just as they are. Most of the reports given elsewhere are extracts from letters.

GLEANINGS IN THE "WINDMILL DAYS."

A REQUEST has been made that we issue a call for a show of hands from those who were subscribers of GLEANINGS 40 years ago, when our only source of power was that derived from a windmill. We would appreciate it very much if all such would give us their names, in order that we may publish a list of them. We are afraid that there are but few, after all these years, who are still keeping bees or reading GLEANINGS; but we are sure our readers would be glad to know who they are at this time.

FOUL-BROOD LAW IN TENNESSEE.

THE Tennessee State Board of Entomology has just issued (June, 1912) Bulletin No. 6, which is the amended law creating the Tennessee State Board of Entomology, and also the apiary-inspection law. One thousand dollars and expenses is the appropriation provided for the inspector, who, by the way, is appointed by the State Entomologist.

The first six sections relate to the appointment of the inspector, his authority, treatment, sale of infected bees, etc. Section 7 is as follows:

SEC. 7. Be it further enacted, That any person, firm, or corporation who shall bring into the State of Tennessee any colony or colonies of bees, shall immediately notify the Inspector of Apiaries of such fact, stating where such bees are being kept, and shall at the same time file with the said Inspector a certificate from the duly appointed Inspector in the county or State from which such bees were shipped, stating that such colony or colonies are free from any infectious or contagious disease; and in default of such certificate it shall be the duty of the Inspector of Apiaries to proceed to examine such bees, and ascertain whether they are free from foul brood or other disease. Any person, firm, or corporation who shall fail to notify the Inspector as required by this section, for a period of ten days from the arrival within the State of Tennessee of such colony or colonies of bees, shall be guilty of a misdemeanor, and upon conviction shall be punished by a fine of not less than five dollars nor more than twenty-five dollars.

Section 8 requires the boiling of any honey used in making queen-cage candy, at least thirty minutes, and also specifies that any person engaged in the rearing of queens shall have his apiary inspected at least twice during each summer season. If disease is discovered, all shipments of bees or queens are to be stopped until the inspector shall declare said apiary free from trouble.

A WIRING "KINK."

IN talking with Mr. A. B. Anthony, of Sterling, Ill., in regard to wiring frames, he mentioned a point which is very important. He makes no effort to get the wires absolutely tight, but still takes care that they be not too loose. After fastening in the foundation he takes pains to see that the upper wire is imbedded with what sag there is below an absolutely horizontal line. The middle wire he leaves straight, and the lower one he imbeds with the slack above the horizontal. The most sag is in the lower part of the combs, and it will be seen by this plan that the lower wire can move down with the foundation so that there will be less buckling. Mr. Anthony's frames are slightly shallower than the standard, so that he uses only three wires. If he used standard-sized frames, which have four wires, we suppose he would divide the amount of sag of the wires in the same way.

WHY DO SWARMS CLUSTER BEFORE LEAVING?

It is also Mr. Anthony's belief that swarms cluster until they can get word from some bees left in the parent colony that all is well—in other words, that there is means for a new queen left, so that the life of the parent colony is assured. To prove this theory, Mr. Anthony selected a swarm which left with a virgin, there being at the time one more virgin left in the parent hive. The swarm went into one of the upper branches of a tall tree, and clustered. Without making any effort to reach the swarm he quietly went to the parent colony from which the swarm had issued, and destroyed the remaining queen, so that the condition of the bees of the parent hive was hopeless. In about twenty minutes the swarm in the tall tree broke up; and, although accompanied by a queen, they returned to the parent hive. Mr. Anthony has not tried it more than this once; and while he realizes that his theory may be wrong, he knows that it certainly worked in this one case and saved him a disagreeable job.

HONEY STATISTICS FOR OHIO.

THE annual report of the Secretary of State conveys the strange information that Ashtabula Co., with 975 stands of bees, produced 63,268 lbs. of honey in 1910, or an average of 65 lbs. per stand. This (Medina) county is credited with 6870 stands of bees that gave only 386 lbs. of honey the same year, or an average of only an ounce per hive. In respect to figures, these cause us to doubt their traditional truthfulness; but the blame may be justly attributed to those who handle said figures. While the yield in 1910 is easily believed for Ashtabula Co., the tremendous number of colonies credited to this county seems all out of proportion, as but few bees are kept in Medina County except at the Home of the Honeybees, and even these would not account for more than one-sixth of the number reported.

COMB-HONEY CANARDS AND SUNDAY PAPERS.

WE have never taken much stock in Sunday papers—not so much because they are printed on Sunday, for, as a matter of fact, they are probably all finished before daylight on Sunday morning—but because of the fact that an immense army of boys and young men, who ought to be in Sunday-school, are engaged in selling these papers at newsstands and delivering them in various homes in our cities. However, the chief objection we have to the Sunday papers is that the news contained therein is

far less reliable than that contained in the papers issued on week days; for, as a rule, such news is garbled so as to be put in the most attractive form, and compiled in such a way as to be made interesting, whether truthful or not.

An illustration of the fact just mentioned is given in the St. Louis *Globe-Democrat* for June 30. In an article headed "The Busy Bee," the following statement appeared:

In fact, it may be confessed, though with regret, that man has gone still further, and has not only become able to produce honeycomb, but has also successfully, though to no great commercial extent, filled such comb with adulterated honey and capped the cells over, without putting his honeycomb into the hive at all! To such a pass has invention and adulteration of food come.

We have written the publishers, the Globe Printing Co., protesting against such a statement and have their assurance that they will publish at least a part of our letter correcting the mistake. But probably not more than one in ten who read the original statement will notice our reply.

MIGRATORY BEEKEEPING V. WINTERING BEES IN THE NORTH; SHIPPING IN CAR LOTS WITHOUT COMBS.

ONE of our correspondents, Mr. T. T. Taylor, in the Heads of Grain department of this issue, raises the question why it would not be cheaper to buy bees in the South, where they can be reared in large quantities, instead of going to the expense and risk of wintering in the North by the use of double-walled hives or elaborate and expensive bee-cellars. His plan seems to be that it is not necessary to keep bees all the year round, especially at such times of the year as they are consumers and not producers. At the close of the honey-flow he would double up his stocks into big ones, and in a comparatively short time have but little brood and fewer bees to destroy or move to pastures new.

If ever a plan of this kind was feasible it was during the past winter and summer; but, so far as we know, Mr. R. F. Holtermann and ourselves were the only ones in the United States who attempted to ship bees by the carload from the South to the North. The venture was a financial success with us, and probably was with Mr. Holtermann. In such migratory beekeeping every thing would depend on whether there would be a fair flow of honey after the bees were moved northward. If there was a big flow, bees might gather enough to pay the freight or even their first cost; but it would have to be a big yield to do it. So, generally speaking, we would have

to figure that the bees could not pay for themselves the first year. If that were true, they would have to be wintered over, and that would destroy Mr. Taylor's well-laid scheme. But our correspondent does not contemplate moving brood, combs, or honey. He would move just the bees in suitable shipping boxes without combs or honey, and in their stead supply queen-cage candy.

The scheme is not as wild as it looks. There has been quite a little correspondence between Mr. F. B. Cavanagh, of Hebron, Ind., and Dr. E. F. Phillips, of the Bureau of Entomology, Washington, D. C., and ourselves as to the feasibility of shipping a carload of bees in pound packages or even five-pound lots, without combs. Mr. Cavanagh's idea was to secure a crop in the North, then move the bees without combs after brood-rearing had practically ceased in September, say, and then ship all to the South; build them up well, on another set of combs, secure a crop of honey in the South, and after that is secured stop brood-rearing by caging the queens, and again move the bees North in the spring and so on back and forth. This would eliminate the northern wintering problem, and enable the owner with his bees to get two crops instead of one. When bees are shipped without combs in one-pound or five-pound packages, the freight would be materially reduced. Indeed, one could ship nearly a thousand packages without combs. Of course, the owner would have to go with them, and wet them down with a watering-pot, for bees in transit require a great deal of water.

We may say in this connection that, if the beekeeper makes the right kind of preparation, and gets in touch with the various railroad lines over which the bees are to travel, he can usually reduce the days on the route to half the regular time. Our last carload, for example, came from Florida in six days; and if, for instance, bees were to move from Nevada to California, they ought to go through in two days.

Our Mr. Ernest Marchant, son of A. B. Marchant, knows how to move bees in car lots; and there are many others in the country who can do the trick provided they will follow the directions we can give. The two carloads of bees which we secured from the South produced enough honey, although split up into nuclei on arrival, to pay about a third of their entire cost. We sold enough bees out of them to pay the rest of the expense, and

now have considerably more than two carloads of bees left with about 5000 pounds of honey in the hives. Mr. A. B. Marchant, before shipping them north (had the season been at all favorable, which it was not), could have secured a crop of tupelo honey. As it was, he obtained a light crop, and then shipped the bees north.

There is another feature about this proposition that looks attractive. Bees shipped without combs would not carry disease. At the present time there is a great outcry in California against the shipment of so many carloads of bees from other States; and in some cases, at least, American and European foul brood have been imported. We can not blame the beekeepers in California for complaining; yet if the bees were shipped in wire-cloth cages holding about five pounds, and if they could be shipped through successfully (and we believe they could), all danger of disease would be eliminated, and the cost of shipping 1000 combless colonies would be no more than 250 colonies on combs in hives. If the beekeeper owned a set of combs and hives at each end of the route, and could arrange to let all the brood hatch by caging his queens before shipping, he would stand a fair chance of securing two or three and possibly four crops in place of one or two. Where is the man of brains and capital to try it out? Perhaps a group of beekeepers could chip in bees and money and hire one of their number to carry out the scheme. This would divide the cost so that if the project proved a failure such failure would not fall upon one man.

We believe it is *possible* to make a scheme of this kind work, and make money; but we would not advise any one to enter into it on a large scale, as he might meet with catastrophe. It would require experience as well as skill.

There has been a big trade in bees shipped by the pound and half-pound. It has passed the stage of experiment and now is an assured success; and, moreover, it eliminates practically all the danger of spreading disease.

It is possible that legislation will in time require the elimination of combs, brood, and honey when bees are shipped from one State to another, or from one locality to another.

We should be glad to have this question discussed; and if there is any beekeeper or group of beekeepers who feel inclined to carry out the experiment we should be pleased to give them all the information they may require.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

H. H. BROWN, replying to your questions, just once I saw a laying worker deposit eggs. I don't know whether a laying worker lives longer than other workers—would guess she does. If young brood is furnished, I *think* a young queen will be often reared, putting the laying workers (not worker) out of business.

A. I. ROOT, I'm interested in watching Terry and you trying to reach the 100-year goal; but I'm not so wonderfully stuck on waiting to see the outcome of flying-machines, etc., p. 457. New things will be coming up all the time whose outcome you will want to see, and you'll never want to get away. Besides, I'm sure I can watch the outcome just as well after I get to heaven (if I want to), and have a more comfortable seat while watching the performance.

P. C. CHADWICK, p. 435, they'll say black stings are stung more than bare legs, not because of color, but because of cloth. Try one stocking black and the other white. [It was Jay Smith, if we are not much mistaken, who reported how two dogs, one black and the other white, went racing and "cavorting" through his beeyard. The black dog was badly stung, while the white one was not touched at all. A good many reports have indicated that bees will sting black clothing when they will not attack white. We do know this—that they will attack black spots in clothing; and we suppose this is because they think they are striking at the eye of their victim. Some people say that bees do not think or reason; but they do something that is equivalent, at all events.—ED.]

THE *Beekeepers' Review* gives a scheme for queen-candy that, when used for mailing queens, is foul-brood proof. Don't use honey at all—use syrup of granulated sugar, with enough glycerine to prevent granulation. [Here is a recipe that is said to be foul-brood proof also:

The candy feed such as I sent in queen-bee mailing-cage is made of granulated sugar, glucose, coffee A sugar, cream of tartar, and water, boiled to 238 degrees. The mailing-cage is the common Benton cage made by the Falconer Mfg. Company. This same kind of food I have, brought through since January, 1912, nearly all of my bees. I could not feed them last fall, on account of sickness and death in my home. I have a number of letters from beekeepers who used this food this last spring with good results.

Blackstone, Mass.

C. F. FULLER.

We have not yet had an opportunity to try it, as we have not yet secured a high grade of glucose nor any kind that is fit for the purpose.—ED.]

MR. EDITOR, I've urged glass as wide as possible in shipping-cases, to make a fine show; but now if you're going to throw out glass altogether I'm with you. It will be a relief not to have to worry for fear veneering is done—strength of case and saving in expense count too. [Good! glad to know that we can join hands in the shipping-case proposition, even if we can not agree on the width of glass. A shipping-case with solid wood, front and back, has about twice the strength of one having a wide glass front. Try it out and see what a difference there is in the rigidity of the boxes. In proportion as the shipping-case is weak or wobbly, in that proportion we have broken combs and a lot more that are leaky.—ED.]

LOOKS rather logical, Bro. A. I., p. 460, instead of punishing the murderer who is crazed by drink to punish the man who sold him the drink. But it's better to go for the men "higher up." The saloon-keeper is doing a legitimate business. Go for the men who make it legitimate, the men who make the laws, and, still further back, to the Christian men who vote for them. If you electrocute all who are responsible for murders committed by men in drink there will be some thinning out of our church rolls. [But the trouble is, doctor, we can not get the men who are higher up—too many times their tracks are covered. By getting the saloon-keepers we may be able to get them to "squeal" on the men back of them. Of course, you can never get the voter. He can vote for the meanest man that ever lived. It would be an excellent law that would enable us to hold any saloon-keeper liable for any damage a man may do to life and property as the result of liquor that he sells him. Such a procedure would enable us to reach the man higher up. For example, in Ohio just now our officers are getting after our State senators and representatives who have taken bribe money in consideration of their votes in the General Assembly. Three men have been found guilty, and sent to the penitentiary. A lot more have been indicted; and the prosecutor says he will send the whole bunch of them to the penitentiary. Well, it happens that these indicted men are beginning to cry out "Enough!" They are now willing to "peach" on the men higher up. Misery loves company. The bribe-taker is not always going to keep still. It looks now as if we were going to get some of the bribe-givers.—ED.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

No more correct statement was ever made than that of Mr. Holtermann on page 228, April 15, that the best place to get foundation drawn out is in a super over the brood-chamber of a strong colony.

* * *

The Editor says, April 15, p. 223, "It is true that still air, although the temperature be much colder, is not nearly as severe on bees as a warmer temperature when a gale is on." Quite true. The same rule applies to bees as to human beings.

* * *

Passing under some basswood trees yesterday by the sidewalk I noticed they had dropped their blossom buds before opening; and, in fact, the entire flower stem, the sidewalk being nearly covered with them—something I have never before seen.

* * *

Mr. Foster's description of his early home on page 330 was profitable as well as pleasant reading. Every such home is worth to the country more than a goldmine. If beekeeping makes such homes possible, hurrah for beekeeping!

* * *

Dr. Miller, Apr. 15, p. 223, says that poultry in the United States in 1910 was worth 14.79 times as much as bees, "*according to the Bureau of Census.*" Pretty poor authority on bees. Some time ago a man taking the census refused to take my bees at all.

* * *

One of the charming sights the beekeeper enjoys in late June is the luxuriant fields of alsike clover with its innumerable blossoms of every shade, from white to red; and their fragrance! how delightful! Surely "Its smell is as the smell of a field that the Lord hath blessed."

* * *

Testimony as to the value of sweet clover continues to accumulate, and I dream of the time when in some measure it will take the place with the beekeeper that basswood has filled, as it blooms at about the same time. I believe that, when the present prejudice has died out, sweet clover will prove of great value to both farmer and beekeeper.

* * *

I wonder if we beekeepers half appreciate the care the editors of our journals take to give us just the information we need at this season. Just look over the May numbers of GLEANINGS and see how many

articles there are on making increase, putting on supers, etc., by such authorities as Doolittle, Townsend, Dr. Miller, and others.

* * *

I was rather surprised at the statement of P. C. Chadwick, p. 297, May 15, that sealed brood will stand a temperature as low as 40 degrees. I am glad to know it, for the advice about spreading brood is just as good here in the East as in California. I have found that a good way to build up those weak colonies is to change eggs or young larvae for mature brood, and so quickly get them in good order.

* * *

There was a good show of clover the past spring; but the weather was cold and rough until June 22, and by July 1 we were in the grip of a severe drouth with tropical heat; and by July 10 apparently most clover was dried up; but bees have done very well. I think it must be one of those years Mr. O. O. Poppleton, of Florida, tells of, when the bees make honey from fence posts. But I notice it has the flavor of clover.

* * *

The theory and practice of putting on supers by Dr. Miller, page 281, May 1, is not only worth careful reading by beginners, but careful study until thoroughly understood. A good deal of light has been thrown on this subject in comparatively recent years. I used to think it unnecessary to put on a second super until the first was about two-thirds or three-fourths full, so that, while the bees were finishing the first super, they could begin on the second; but I have found in recent years that in a good flow a good colony will sometimes fill two moderate-sized supers almost as soon as they will one.

* * *

I greatly fear the article on p. 275, May 1, on extra rapid increase, will mislead beginners in beekeeping. Thirty colonies from one, and that in a poor season, we are informed! I am naturally skeptical, and so doubt if one experienced beekeeper in fifty or even a hundred could do as well, and produce thirty colonies from one that would be worth wintering, even in a good season. Much more helpful to me are "Lessons Learned from Mistakes in Beekeeping," page 283. A child learns to walk quite as fast when he falls as when he stands erect. We must win strength by struggle in this world. I haven't much use for the man who is so angelic he never makes a mistake.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

Extracted honey scores again. A small crop was secured where comb honey would have been impossible.

* * *

I fear some queen-breeders are like fancy poultry-raisers — sacrificing productive qualities for showy stock.

* * *

Paint your hives. A good coat of paint occasionally will make a hive last for years. Without it the hive is soon sun-checked, season-cracked, warped, and fit only for kindlingwood.

* * *

I am in receipt of a copy of "Texas Beekeeping," the compliments of Mr. Louis H. Scholl, who is also its editor. It is issued by the Texas Department of Agriculture, and is one of the most complete works of its kind I have ever seen.

* * *

A honey-buyer gave reports of how many cases of honey he bought here, and how many somewhere else, which was, I believe, entirely true; but he was implying that this was new honey, while the fact was that much of it was last season's crop, but was used to influence the market in the buyer's favor.

* * *

Bees as property are much like animals: well cared for they are a valuable asset; but poorly cared for their value decreases according to the care given. As for ability to conform themselves to conditions, they are in some respects superior to man, especially in that they refuse to reproduce when there is nothing coming in on which to feed their young.

* * *

A beekeeper of more or less prominence, in speaking of the difference in the growth of the sage this year and last made the assertion that last season the growth was much longer and contained from twelve to fifteen buttons on each stem; but as a matter of fact there are rarely ever more than ten buttons on a stem, while five to seven is the rule. I mention this to show how closely the flora is observed by some.

* * *

How ruthlessly our theories are sometimes upset, and a set line of practice becomes impossible! Nearly two years ago I wrote an article for this journal on management of bees, in which I spoke of hives at the beginning of the honey flow containing from 7 to 17 frames of brood. I was

perfectly justified in every assertion made; but since that time I have not seen a hive with over ten frames of brood, and some lines of management spoken of in the same article have not been at all practical since; yet I am sure I will return to that line again under more favorable conditions.

From this, one can see the difficult position of the novice who reads, and decides to follow a writer's suggestions; but conditions change, and he knows no way out of his difficulty until he has knowledge that will point the way to the next best course to pursue.

* * *

How often it happens that a weak colony will struggle nearly through the entire season, requeening and getting built up, only to bloom out the following season with a vigorous young queen and a hive full of bees, while the best colony the previous season will struggle along with an old queen and make a dismal failure! Queens in this climate should not be carried over to the third season. Two seasons of active work will put them beyond their best, and I believe we should all be better off if we would practice requeening after every season's honey flow.

* * *

July 18 marked the end of another beekeeper. Mr. Walter Parrish, once a prominent queen-breeder of Lawrence, Kansas, and widely known through this branch of the bee industry, passed away. Mr. Parrish had every promise of becoming a renowned queen-breeder, and was receiving daily orders for his queens in the summer of 1910, when, to his astonishment and dismay, he discovered foul brood in three colonies he had purchased. This ended Mr. Parrish's queen-rearing. Though receiving daily orders, he at once began to return his customers' money instead of queens. Though his queen-rearing colonies were free from disease, he refused to let any customers take risks he would not care to take himself. Mr. Parrish had never been strong, and this was quite a shock to his ambitious nature, and probably helped to undermine his health. In the fall of 1911 he decided to come to California, which he did; but his health was not regained, and he failed rapidly, the end coming as stated above. What better tribute could be paid to this young man, in his thirty-first year, than that he sacrificed his business for the sake of his customers' welfare? He had many customers in California.

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

THOSE PICTURES OF L. C. ROOT.

When the July 15th issue appeared I enjoyed those pictures of L. C. Root very much indeed; and it has occurred to me that GLEANINGS ought to give more pictures of the other well-known beekeepers of the country in much the same way. It is a pleasure to see these old veterans, snapped right among the bees. It would be appreciated by all of us, I am sure, if we could have a glimpse of the many old-timers as they look to-day.

* * *

CHUNK HONEY.

It seems that our northern friends are trying to insist on the name "chunk honey" for the product known entirely as "bulk comb honey" in Texas. Just why this should be, we can not understand. For a Texas beekeeper to use the term "chunk honey" for bulk comb honey is looked upon as gross ignorance of the real name for this product. Bulk comb honey is the proper name, and it should be used. Being strictly a product of commercial importance, originating in Texas and named by Texas beekeepers "bulk comb honey," it is only right that others should be expected to use that name.

The term "chunk honey" is entirely out of place in the Texas beekeepers' vocabulary as a general rule. That name is out of date, and the product now produced as bulk comb honey is so much superior in the way it is produced, packed, and marketed, that the newer name is well warranted.

It is hoped that the old-fashioned term "chunk honey" will be put aside, and "bulk comb honey" used instead. The latter term covers all comb honey produced in frames or otherwise, then cut out and marketed. There are many ways in which bulk comb honey is marketed. However, in Texas, the home of this kind of comb honey, it is almost entirely marketed in standard-sized tin packages in wooden cases.

* * *

MOVING BEES WITHOUT SCREENING.

Although we have argued against taking the risk of moving bees with the entrances of the hives wide open, the subject comes up again every once in a while. There would be no objection to this if it were not a fact that beginners are apt to be misled. I have seen several instances of this kind. Of course, there is not so much danger connected with this method of moving when the automobile truck is used, as in the case of J. Van de Vord, p. 445. With

horse-drawn vehicles it is by far the best and wisest plan to close the hives securely upon all occasions, providing for proper ventilation during warm weather, of course.

After giving open-entrance moving a trial upon several occasions, both during cool and warm weather, I have concluded to denounce it under all circumstances. It does not work satisfactorily enough in the first place, especially if colonies are strong or the weather is warm, as the bees cluster outside and all over the hives. They often crawl all over the wagon in spite of frequent smoking. This is the result with night moving, and during the day such moving can hardly be done. It takes a lot of time and precaution to get them on the wagon with a lot of smoking; and while they will remain reasonably quiet while the load is in motion they come out of the hives as soon as the wagon stops. This is bad if a sudden stop must be made, as in case of an accident or otherwise while on the road. We do not like this method. It is safer and wiser to screen the entrances.

* * *

HIVE-NUMBERS.

Manilla hive-tags boiled in paraffine, and cheap to replace when they are worn out, sounds good enough, Mr. Editor and Dr. Miller; but the matter of fastening them to the hive—that is the question I am driving at. I want a number that will last while I can shift it from place to place in a jiffy—that is to say, one that I can put on either end of a hive or super, if the hives are reversed end for end; also if I want to raise the brood-chamber up, and I'd like to have the number tag on the lower one just given. This is especially necessary with our numerous manipulations with the divisible-brood-chamber hives. It would cost me thousands of tacks and a great lot of tacking, with ten thousand supers in use, any of which may come into place at any time where it must bear the number tag. Understand?

Well, I am tickled because I have invented such a tag, and have been using it for several years. It works like a charm, can be placed on the hive in a jiffy, taken off and placed somewhere else in a jiffy, and not a single tack, nail, nor staple is needed; and it is cheap enough for me, especially if the value of such a number tag is considered. It is difficult to describe it, so I'll make drawings of it and show you. It can be made to fit your hives too, Dr. Miller, as well as yours, Mr. Editor.

Conversations with Doolittle

At Borodino, New York

USING "BAITS" TO THE BEST ADVANTAGE.

I have read with interest what you have been telling us about bait sections; but you have not told us how to use them to the best advantage. Some put them in the center of the super so that the bees can work both ways from them, drawing out the foundation on either side till the ends of the supers are reached. I may not be up in this matter; but it looks to me as if it would be better if there were some way of using them so that the sections near the ends of the super would be finished up within a few days of the time the center ones are. Where the sections at the ends of the supers are two weeks behind in finishing, I find that those finished first in the center of the super are often badly travel-stained, so much that they have to go in a grade lower than would be the case could the super come off when these are first finished.

Something depends on the number of baits we may have at the beginning of the season. To get at the matter we will suppose we have 100 colonies which we expect to put supers on for section honey; that we use a super holding four rows of sections, 11 sections in a row, or 44 sections to the super, and that we have only 100 baits. I know of no better way to use them than to put one of these in the center of one of the center rows. This bait will have five sections filled with foundation on either side in that row, and in the other three rows. The bees will begin work in the center of the supers; and if the season is poor, or the sections put on early, the center sections in such supers will be finished long before those next to the ends of the supers. But we have the consolation that, even in this condition of affairs, the bees enter the sections much sooner than they otherwise would; and through this we not only secure more honey but discourage swarming.

If we have 200 baits they should be put in the center of the two outside rows. In this way the bees will commence work all through the center of the super at the same time. The drawing of the bees to the center of the two outside rows makes it warm in the middle rows, and for this reason the bees will begin to draw the foundation there as soon as they will on either side of the two baits. I find that baits are mostly used in this way unless there are as many as 400, when one is put in the center of each row. Then if the bees are somewhat crowded for room they will fill two-thirds of the sections so they will be near completion at about the same time, while the other third will be only a few days behind in all ordinary good seasons. Many tell me that 400 baits for 100 colonies in the spring is all that is necessary, and that they would not use more if they had them, other than to fill supers full of them, and put such on

the hives when the flow is at its height, under which circumstances they will be filled and completed so that they will go as No. 1 or fancy honey, which they claim can never be the case where sections are used as baits. I do not agree with those who argue thus; for if I could always have things just as I like them I would have 800 or 1200 baits for the 100 colonies, the latter preferred. With that amount I would fill the 100 supers in this way: I would put one in the center of each of the four rows; then I would put one in each of the four rows at either end, one section away from the ends of the supers. This would make each of the rows as follows: Beginning at one end there would be first a section filled with thin foundation, then a bait; then three sections filled with foundation; then a bait; then three of foundation; then another bait; and, last, one of foundation. This is the way I have used my supers for thirty years, if I could only furnish the 1600 partly filled sections from the year before. And I wish to go on record right here as saying that, so far as I can see, a super filled in this way has as good effect toward the prevention of swarming as does the putting-on of the first super of the season filled with all baits. Of course, with all baits and a good colony the *storing* will go on in all of the 44 about equally. With the twelve, storing will commence first in the *baits*, while the foundation is being drawn. But at the end of three or four days there will be little difference. Even the four corner sections will apparently be just as well filled as those at the center, when the whole of the 44 in the super will all come up to completion at the same time.

There is no prettier sight than a super of sections all alike in advancement, with not a cell yet sealed, though filled with water-white honey which sparkles and glistens in the morning sunshine. Not even the whole of the 44 sealed sections, with their snow-white cappings, look nearly so enchanting to me as does this mass of sparkling smoothness, and this is just what I have seen hundreds of times in the first supers of the season when I had enough baits. And where the season allows of their coming to completion thus, the man who could tell which sections contained the baits and which the foundation would have a sharper eye than most apiarists have, to say nothing of those who know of honey only as they buy it in the market.

General Correspondence

WHAT HAS THE SEASON BEEN?

Reports from All Sections of the Country

From the mass of correspondence that has been coming in from day to day we select out, as far as practicable to do so, a sentence or two that will give some idea of the honey season, and what it has been for the locality represented. We append here a list of such letters boiled down to one or two sentences, giving the name and address. These reports relate mainly to the white-clover districts, as will be noted.

ALABAMA

By July 1 I had taken 211 sections of beautiful comb honey from two colonies, spring count.
Selma, Ala., July 6. F. G. RILEY.

It has been a most unusual season here. The winds have been blowing like March weather all the spring, and through the flow of sweet clover, drying out the nectar. We shall do well to get a quarter of a crop.

Letahatchee, Ala., July 30. W. N. RANDOLPH.

CALIFORNIA

Honey crop is a total failure. Bees will probably get enough to winter on.
Paicines, Cal., July 11. GEO. W. MOORE.

We beekeepers have got a "black eye," sure. Nothing doing. Later reports, from higher altitudes, are more favorable.

Descanso, Cal., July 5. E. P. ST. JOHN.

Conditions indicate a small crop.

Standish, Cal., July 11. H. A. HARTMAN.

The honey-flow has not been very good here this season. The spring was late, and the weather was cold.

Nevada City, Cal., July 22. FRED A. THOMAS.

COLORADO

The season is a little backward, but the outlook for an average honey crop is fair.
Canon City, Colo., July 13. W. G. WRIGHT.

The honey crop to date is very poor, owing to cold weather. It can not be over half a crop in Northern Colorado.

Greeley, Colo., July 20. CHAS. ADAMS.

Honey crop in this location will be a little below the average. There are about 1000 colonies in this county, and will average one super each this year.

Canon City, Colo., July 20. V. P. CUTLER.

Prospects for flow are good, as a large quantity of clover is just beginning to bloom, and weather is less windy. The one danger is hail.

Las Animas, Colo., July 9. L. H. SWEETMAN.

Prospects are good in Colorado for a crop this year, though the losses have been heavy, and alfalfa is being cut very early. I believe that more honey will be shipped this year than last if present conditions prevail.

Boulder, Colo., June 25. WESLEY FOSTER.

The outlook for honey from this part of Colorado is not very bright. There are acres and acres of sweet clover, and it never looked better than it does now; but the weather through July has been cloudy and rainy, and bees could not get out to gather honey. I have 250 stands, and have taken off only six cases so far.

Delta, Colo., July 28. GEO. F. LESTER.

According to estimates just made, the honey crop on the Western Slope will total 35 or 40 cars, which includes the output from every station from DeBeque to Montrose. This is considerably in excess of the shipment for last year, as only 22 cars were sent to the buyers, netting the growers about \$80,000. The amount of honey which will be gathered from the apiaries around Montrose this year has been conservatively estimated at between six and seven cars, which is between

one-sixth and one-seventh of the total output. The beemen down the river from Montrose lost a number of bees last winter; but from Montrose south the loss is reported as being very small, and almost a full crop is expected. Each car, it is estimated, contains between 1000 and 1100 cases of honey, and is worth between \$3000 and \$4000.—*Montrose Weekly Press*, July 18.

CONNECTICUT

The honey flow is very poor. The future depends on the weather. The crop is not as good as last year. It has been very dry in this locality.

Bristol, Ct., July 22. MAPLEWOOD APIARY.

IDAHO

First flow light, owing to weak colonies and cool weather. Prospects are fairly good for next flow.
Meridian, Ida., July 10. E. F. ARWATER.

No swarms until after July 9; best white-clover and snowdrop flow we ever had; but the weather is so cool and cloudy that bees work only half the time.
Fraser, Ida., July 12. F. F. GEORGE.

INDIANA

We can not expect much from Indiana and Illinois this year, for two reasons—tremendous winter losses and a short clover crop. What little clover we have is yielding excessively, and weather conditions are fine.

Indianapolis, Ind., July 5. W. S. POWDER.

Abundance of bloom; basswood and white and alsike clover; nectar is flowing very slowly, especially from basswood.

La Porte, Ind., July 5. C. H. WAIR.

Clover flow is practically over; have secured a very small crop. Colonies were in fine shape, and no swarming. Clover did not produce the nectar, from some cause.

Odon, Ind., July 5. A. M. KECK.

Bees are booming; weather ideal; bloom plenty; result, best crop of honey for three years. I am getting 20 cts. per lb. by crate.

Richmond, Ind., July 4. M. H. WOLFER.

We are having a very fair honey-flow from red and white clover. The flow began about July 1; and with the good rain of yesterday it will continue several weeks, we trust. Our 600 colonies are in surprisingly good condition considering the increase.

Hebron, Ind., July 8. F. B. CAVANAGH.

There is an abundance of swarming. Basswood yielded well, but not many trees. White clover is fairly abundant, but does not seem to yield well, so that the prospect for a surplus is very doubtful.

Ladoga, Ind., July 9. DR. J. B. TALMAGE.

ILLINOIS

Clover flow is light—only one week; plenty of bloom yet, but no nectar. Milkweed and basswood yielded well; will get about 40 lbs. comb honey per colony.

Edinburg, Ill., July 18. W. H. STUMM.

The honey-flow thus far has been very good here; but owing to the severe winter losses of bees the honey crop will probably be no larger than last year, although of much better quality.

Beardstown, Ill., July 15. H. W. DOERR.

Half a crop of white honey in this part.

Versailles, Ill., July 15. D. C. CONNELL.

Bees are just finishing the best basswood flow I ever saw—three supers to the strong; three per cent loss last winter.

Hull, Ill., July 6. J. L. BLACKETTER.

The white-clover honey crop has been a failure in this locality. There was an abundance of white-clover bloom, but during this period of the best yield, from May 20 to June 20, we had too much wet and cloudy weather.

Nashville, Ill., July 12. S. P. SCHROEDER.

Bees swarmed in May; have nearly filled brood-chamber; nothing in supers yet, even strong colonies not making much honey.

Mackinaw, Ill., July 11. G. S. ALLEN.

Prospects for a honey crop are a failure with me. I might get 50 lbs. from ten stands.

Pittsfield, Ill., July 5. FRED TROUTNER.

Prospects are good for a big honey crop. White clover is in full bloom.

Freeport, Ill., July 5. A. E. LONG.

IOWA

There seems to be a pretty good honey-flow here at present. There has been much swarming in my yard for a week or ten days.

Leon, Ia., July 4. EDWIN BEVINS.

We have had the best season so far in several years. Clover gave a big yield, and dandelions and willows gave an immense amount early.

Lake City, Ia., July 10. IRVING WERNICK.

Honey flow is over; clover is drying up; strong colonies average about 50 lbs. extracted each; but most colonies are weak, due to hard winter and late spring.

Dixon, Iowa, July 8. E. A. DONEY.

Bees came through the winter in poor condition, and dwindled down badly during April and May. I can not see more than half a crop. Drouth has cut clover and basswood short.

Elkader, Ia., July 22. HERMAN AHRENS.

KANSAS

Basswood, bee clover, and catnip yielded finely. White clover was a total failure.

Tanganoxie, Kan., July 9. CARL BAERNHART.

KENTUCKY

Honey has been coming in very slowly; flow is about over; it will not exceed one-fourth of a crop.

Richmond, Ky., July 5. CLIFTON WEAVER.

There has been too much rain for the honey crop. Plants are growing well; and if the season is favorable from now on we may expect a good fall flow of honey. I have failed to get sweet clover to grow.

Livia, Ky., July 4. HUGH L. LYNN.

The honey crop for Bracken Co. will be about an average one. This is the best flow we ever knew; but there are not enough bees to gather it. The flow is entirely from sweet clover. I have not seen a dozen bees on white clover. I have one colony that will extract at least 250 lbs. of honey.

Bradford, Ky., July 22. M. A. AULICK.

Spring flow was a failure. Bees are very short of stores now. Some extra strong colonies have stored a little dogfennel honey, very dark and slightly bitter. Worst honey season I ever saw.

Kevil, Ky., July 5. J. G. NANCE.

MARYLAND

The honey yield is running from 75 to 125 lbs. to the colony.

Aikin, Md., July 5. J. FORD SEMPERS.

This has been a very good season for bees—much swarming, and the best honey-flow in many years. However, from one-half to two-thirds of the bees died last winter, so that the honey crop will not be large.

Frederick, Md., July 19. F. D. COVELL.

The honey crop in this section is fully up to the average, or a little better—mostly clover.

Lloyds, Md., July 6. JOHN THOMPSON.

MASSACHUSETTS

I do not expect to get over a third of a honey crop this year. Bees worked very little on white clover. I may get a little fall honey, as we are having rains now—almost three inches since the 11th of this month.

Swampscott, Mass., July 24. G. C. GORDON.

The honey crop this season is exceptionally good.

Greenfield, Mass., July 18. L. A. LOVELAND.

MICHIGAN

Up to date, bees are doing finely. My bees wintered well, and swarmed early. I got quite a few natural swarms in May, and some hives have the third super on—very good for this locality. The honey is the whitest I have seen for a long time.

Estey, Mich., July 8. MILO WRIGHT.

The honey crop in Ionia Co. will be very short, owing to the heavy winter loss of more than three-fourths of our bees. Recent rains are favorable for a good late flow.

Ionia, Mich., July 22. A. H. GUERNSEY.

We have been having fine weather for a flow, and the bees are doing well; basswood is just opening. Many bees winter-killed where not well protected, and not strong at beginning of flow.

Highland, Mich., July 8. R. D. MILLS.

I had a good flow of clover and basswood here; plenty of wet to make good fall pasture.

Glenwood, Mich., July 18. E. E. MOTT.

The honey-flow from raspberry and clover is good. Willowherb is out, but yielding slowly; basswood will be in bloom in a few days. Indications point to a good year generally.

Levering, Mich., July 18. J. D. ROBINSON.

We are having a fine honey flow. White clover and raspberries are abundant; not enough bees to take care of it. I had much trouble with spring dwindling; some lost nearly all their bees.

Wolverine, Mich., July 6. L. K. FEICK.

MINNESOTA

Swarms seem to be heavy. White clover is everywhere. The prospects are good.

Aitkin, Minn., July 9. MRS. J. R. DARLING.

My bees are doing fairly well this summer. There was more white clover than there has been for a number of years. I lost half of my bees in the cellar.

Warsaw, Minn., July 22. R. R. RANDALL.

This is certainly a clover year here in Minnesota, with quite a good flow of honey. Basswood is just coming in bloom; plenty of rain for the former, but too much for the latter.

Minneapolis, Minn., July 12. E. T. EDSON.

Despite the fact that clover has bloomed more profusely than it has any year since 1908, the crop of honey from that source will be very light. The reason for the scanty secretion of nectar is likely due to lack of age of the clover, which is not rooted as deeply as should be, most of it having its start from seed late last fall. Basswood bloom is extremely light, and but one-fourth of the trees are blooming. The yield from same will be insignificant.

Chatfield, Minn., July 18. J. J. KADLETZ.

Two-thirds of the white-clover honey is lost owing to two weeks of storms and bad weather. Basswood flow started yesterday; about one-quarter of the bees remain alive after all the drawbacks we have had.

Swanville, Minn., July 17. JOHN S. LIND.

MISSISSIPPI

Light crop of honey, owing to too much rain.

Foxtrap, Miss., July 18. J. E. C. WEAVER.

MISSOURI

There is not one pound of white-clover honey here; basswood, small flow; no prospects.

Marceline, Mo., July 6. IRVING E. LONG.

One hundred per cent of swarming and ten per cent of a honey crop for this part of Missouri.

Fredericktown, Mo., July 22. JAS. BACKLER.

My bees all died last winter but 12 stands; but very little white clover bloomed this season. Bee clover is fair; will probably get 100 lbs. of comb honey.

Gunn City, Mo., July 8. JAS. A. ADAMS.

Clover crop is a failure; basswood good, but not much of it; no surplus unless from fall flowers.

Napton, Mo., July 5. JAS. T. SHACKELFORD.

Prospects for honey are not as good as last year—too much rain, too weak in spring.

Lohman, Mo., July 11. WM. A. BAUMANN.

We are having the best honey flow here that we have had in years. I have some colonies that have made 175 lbs. of section honey.

Morrisville, Mo., July 20. H. C. DAY.

The honey crop here will be about half a yield for clover and basswood. Too dry.

Unionville, Mo., July 8. FRED H. DRURY.

No surplus honey in North Missouri or Southern Iowa; bees will do well to get winter stores.

Unionville, Mo., July 19. E. F. QUIGLEY.

NEBRASKA

We are having a good flow, but it is getting dry; very few bees to gather it.

Cozad, Neb., July 8. THOS. ATKINSON.

There has been a good basswood flow. The weather being too dry, the other plants have produced no nectar.

Plattsmouth, Neb., July 9. J. N. NEILSON.

The honey-flow is the best in many years. Every thing seems to secrete well. Some have secured already three supers to the colony.

Humboldt, Neb., July 6. J. L. GANDY.

The honey prospects in this vicinity are very poor. A severe drouth is setting in, and the only honey-plants are the milkweed and sweet clover. White clover has entirely disappeared; so if a rain does not soon come, only the strong colonies will make enough for winter. No honey for market.

Pawnee City, Neb., July 11. J. E. BILY.

NEW HAMPSHIRE

The honey season has been fair so far, but would have been much better if it had not been for the cold dry weather in June. We are now having it very warm, with lots of swarming.

Pittsfield, N. H., July 8. HERBERT C. TOWLE.

NEW JERSEY

I report from white clover; 35 colonies produced 3550 lbs.; buckwheat not in bloom yet.

Stanton, N. J., July 22. T. K. COLE.

Never saw so much white clover here before; but its season is just ended, hastened by drouth and heat.

Lyndhurst, N. J., July 5. C. D. CHENEY.

NEW MEXICO

Outlook for honey in Pecos Valley is very gloomy.

Roswell, N. M., July 5. J. W. E. BASHAM.

NEW YORK

We have the best clover yield in a number of years.

Oswego, N. Y. F. H. CYRENIUS.

The cold heavy rains during fruit-bloom made it impossible for bees to work. It is about a month since we have had any rain, therefore the flowers are dying. Bees swarmed a month late this year (June 15).

Kendall, N. Y., July 9. T. H. WING.

I expect to have at least six tons of honey from 101 colonies, spring count.

Middleville, N. Y., July 17. F. H. STODDARD.

Nearly all the reports so far received say "Bees doing finely." Mr. Dines was here this morning, and said he took off 2000 lbs. of comb honey yesterday, and is to take off more to-day. He increased from 180 to 316 colonies. I believe the bees are doing nicely up in Jefferson and St. Lawrence counties, but have had very few reports from there.

Syracuse, N. Y., July 24. F. A. SALISBURY.

We have been getting very favorable reports, and it looks as though there would be a very good crop of clover and basswood. For the last week or two business has increased, which would indicate that beekeepers must be getting honey.

New York City, July 2. NEW YORK BRANCH.

The honey crop here, nine miles south of Syracuse, will be the best in years. There was much white clover and basswood, and it looks like lots of sweet clover.

Fayetteville, N. Y. E. J. BENNETT.

The honey crop is a failure here. First, very wet and cold; then protracted drouth. Surplus is scarce.

Russell, N. Y., July 15. HYLE CRAWFORD.

Tremendous flow since June 20—still on. Basswood is just starting; looks fine. Hives are five to seven stories high. Great is a-sike.

Randolph, N. Y., July 5. GEO. SHIBER.

The long-continued drouth has caused a falling-off in the honey crop in this section; but bees generally are doing well—plenty of early clover honey gathered; lots of absconding swarms; terrible loss in spring dwindling in this section.

Clifton Park, N. Y., July 22. A. L. DOWS.

NORTH CAROLINA

In Western North Carolina the crop will be above the average. Poplar and basswood give an extra good yield.

Cane River, N. C., July 23. W. S. EDWARDS.

The season is fairly good; average about 50 lbs. comb and 11 extracted.

Chadbourn, N. C., July 9. F. R. JORDAN.

OHIO

Fair prospects for a honey crop here.

Spargursville, O., July 7. J. R. COOPER.

Bees are carrying in rapidly now, and have already stored a good amount; and if we have rain to prolong the life of the clover the yield promises to be above the average.

Barnesville, O., July 9. T. D. EVANS.

We are having here in this vicinity one of the best honey-flows on record for this season of the year.

Toledo, O., June 14.

S. J. GRIGGS & CO.

We had a rich honey-flow from May 12 to 28, from locust and poplar. It caused the bees to work in the supers, and we had home-grown honey on the market June 8—very unusual for this locality. Then there was a dearth for two weeks; but since June 16 honey has been coming in freely, mostly from white and sweet clover.

Cincinnati, O., July 10.

REV. E. R. WAGNER.

I am getting a fine crop of mainly snow-white comb honey. Swarming is not a side issue with our bees, but we are getting it under ordinary control at this date. I am having no trouble in disposing of honey in case lots at 20 cts. a pound.

GLENWOOD BEARD.

Magnetic Springs, O., July 1.

The honey flow is the best in ten years—good rain and plenty of white clover.

Lima, Ohio, July 18.

J. A. MOONEY.

Best pasture in ten years; troubled much with swarming, but a fine crop of honey already secured.

Columbiana, O., July 8.

D. M. MCGAFFICK.

In this section the honey crop will be almost an entire failure.

Jerry City, O., July 9.

S. C. REARICK.

The drouth in May and June was unprecedented. Not much honey here this season.

Bloomdale, O., July 6.

M. N. SIMON.

Clover honey was a short crop. Basswood is good—just coming to a close; average about two supers to a colony—70 lbs.

Delphos, O., July 15.

J. H. ALLEMIER.

I believe I have never seen a better honey-flow locally than is on at present. I was surprised in looking over the bees to-day. Bees that I thought had room enough had to have additional supers.

Zanesville, O., July 6.

E. W. PEIRCE.

Reports from bees in this part are not very encouraging—plenty of bees, hives heavy, but few supers on, but bees do not go up into them at all.

Hebron, O., July 11.

MRS. FRANK MCGLADE.

We will secure a good crop of the finest white honey in this section, close to an average of 75 sections per colony, and gathered rapidly, making a predominance of fancy grade.

Beaumont, O., July 12.

J. C. ATKINSON.

ONTARIO

A good colony, but not the best, gained 13 lbs. on the scale yesterday. We should have at least 40,000 lbs., white crop.

Nelles Corners, Ont., July 12.

R. & H.

Bumper crop, bumper quality; bumper swarms; bumper clover flow—six weeks. Beat that if you can.

Toronto, Ont., July 19.

CHAS. E. HOPPER.

PENNSYLVANIA

The crop report for my section of the State shows one of the most wonderful honey-flows that it has ever been my experience to witness.

Philadelphia, Pa., July 20.

GEO. M. STEELE.

My bees are doing finely this year. Some have filled two supers already.

Allegheny, Pa., July 18.

J. A. SPACHT.

This is certainly a great year for honey. The little fellows will pay off the back debt; 108 lbs. from one colony, comb honey.

Washington, Pa., July 8.

J. C. MCNEELY.

It is a very good white-clover yield of honey this year.

Corydon, Pa., July 16.

GEO. WHITCOMB.

Quite a number of bees froze last winter, and some of the remaining are very weak, so they were slow gathering up, but are doing very well now.

McVeytown, Pa., July 10.

J. H. BYLER.

We are having a good honey yield this season all through this section of the county.

New Holland, Pa., July 8.

H. W. MARTIN.

The honey crop will be short in this locality from present indications. Clover is about over, and less than half the bees are at work in supers. I can not speak except from this immediate locality.

Linden, Pa., July 8.

DAVID L. YOUNG.

The yield of white-clover honey is above the average, in both quantity and quality; all over by July 1, owing to drouth the last three weeks of the honey season.

Doylestown, Pa., July 20.

T. C. POTTER.

This has been the poorest year so far for many a year—no clover honey yet, and we don't expect any.

Dayton, Pa., July 25.

J. L. RIMER.

Owing to six frosts in June and one July 1, then the severe drouth from June 20 to July 10, the red raspberry and white clover crop of honey is only a fair one. Bees were too weak to gather a good crop. Good rains yesterday and to-day give us hopes of a good crop of basswood (just opening).

MRS. AFARETTA BONSER.

Costello, Pa., July 11.

QUEBEC

Clover is at its height, and the bees are booming, as the weather is ideal for the secretion of honey. The season bids fair for a bumper crop in this province.

Knowlton, Que., July 5.

J. RAYMOND BALL.

TENNESSEE

This is an exceptionally good honey season here. White clover produced about 36 lbs. per colony. Basswood is now in bloom, and bees are booming.

Harms, Tenn., July 8.

J. A. BEARDEN.

The indications here for a good honey crop are not as they were two weeks ago; however, I think the crop will be very good.

Lebanon, Tenn., July 22.

ROBT. HUDSON.

We have just harvested the best crop of honey I have ever known; fine prospect for a fall flow.

Morristown, Tenn., July 19.

W. A. SPANGLER.

TEXAS

The honey crop in Southwest Texas this season will be an entire failure. In fact, if we do not have some kind of honey flow this fall I am afraid most of the bees will have to be fed.

Jourdanton, Tex., July 10.

M. A. OSBURN.

UTAH

We have a poor prospect for a honey crop this season. The alfalfa weevil got all the first crop of lucerne. Bees wintered poorly.

Hooper, Utah, July 10.

SOPHUS OLSEN.

VERMONT

I have been crowded with my bees this summer—seven colonies. I have taken from them 150 lbs. of comb honey.

Albany, Vt., July 13.

J. M. CARTER.

Bees were gathering honey rapidly from clover, but were cut off by drouth. Basswood is yet to come. Crop is uncertain—one-third or more expected.

Shoreham, Vt., July 8.

R. H. HOLMES.

VIRGINIA

Trade indications point to the best honey-flow for years—mostly of white clover of fine quality.

Staunton, Va., July 5.

W. E. TRIBBETT.

The flow has been good up to this time, and prospects are for a better crop than usual this year.

CHAS. T. THOMPSON.

New Glasgow, Va., July 10.

The prospect is very bright indeed for a good crop of honey through the southwestern portion of Virginia. In this particular section it is the best we have had for three years.

Troutville, Va., July 5.

C. E. LAYMAN.

WEST VIRGINIA

Prospects are fine for a good crop of honey. Most colonies have three supers pretty well filled.

Maud, W. V., July 4.

FRANK P. COOK.

My honey crop this year is 120 sections per colony, spring count. Honey is finished the nicest I ever saw.

Kerens, W. Va., July 23.

C. R. MILLER.

We have an unusually heavy flow of nectar. This, together with the fact that bees wintered better than usual, gives the largest yield for years.

Miami, W. Va., July 22.

JOHN D. THOMAS.

Honey flow commenced June 25, lasting to July 10. From 47 colonies I shall get 1600 pounds of comb honey, being an average yield for this locality. The sources of honey are sumac, cottonweed, chestnut, and white clover.

Pennsboro, W. Va., July 22.

WASHINGTON

Bees bred up well with large brood-chambers; first flow good, then three weeks cloudy weather. Insects have destroyed willowherb, but it may bloom later; clover is not yet past. Little honey taken; prospects poor; a fair amount of swarming. I do not expect any more honey.

Yacolt, Wash., July 15.

H. E. HARRINGTON.

WISCONSIN

No surplus honey in Dane Co.; 90 per cent of the bees died last winter from dysentery and continued cold weather.

Mt. Horeb, Wis., July 10.

L. J. BERGH.

The clover crop is good; weather favorable; fair crop of honey secured. As soon as basswood commenced to bloom, weather turned unfavorable. There will be very little basswood honey in this locality this year. White honey crop will be short here.

Rock Elm, Wis., July 22.

B. J. THOMPSON.

Crop outlook is good here. Bees are working finely. We have had two rains here, which saved our crop.

Augusta, Wis., July 5.

GUS DITTMER Co.

No clover this year in this locality. I just took a trip around the outskirts of Milwaukee, and I notice that even the sweet clover seems to have died out where other years there were miles of it. Basswood is promising, but there is not enough of it, and but few bees left to gather what there is.

R. RODENBERGER.

Menomonee Falls, Wis., July 8.

[In the way of a general summary we may say that the indications so far point to the largest crop of clover honey in years—at least we do not remember the time in over a decade when there were so many favorable reports. As before stated, had it not been for winter losses the large yield of clover would have a strong tendency to weaken prices on Western alfalfa and California sage. However, we do not expect to see any great reduction, because there are a number of sections in the West where alfalfa has not given a large yield. The season in New Mexico and California generally has not been up to the average; but until we can get more definite reports of what the clover crop has been in the East, it will be hard to predict at this time what the market will be. We have been informed that buyers are in the West trying to corral the crop. If they succeed in getting hold of the most of it, and hold prices up, the apparently large yield of clover will not weaken the general market.]

Texas and Florida still report a poor season.

If one will go over these reports carefully he will find one section in the State where the season has been a failure, and another section of the same State where there has been a heavy yield. The shortage in one place and the abundance in another will just about hold things even, with the result that clover honey (for which there is always a good demand) should not drop materially in price if at all. In a general way it will be observed that the clover crop has been better in the more eastern States. In Indiana and Illinois the season has been a little off.—ED.]

Camp outfit, standing by a mammoth blackberry bush, Willamette Valley, Oregon.

A "PROSPECTING" TRIP THROUGH OREGON

BY E. F. ATWATER

Early in October, 1909, our bees being ready for winter, and the greater part of our crop marketed, the writer and Mr. Earle Dilatush took the train to The Dalles, Oregon, and from there to Portland by steamer on the Columbia River, one of the most beautiful scenic trips in the West.

At Portland we purchased a camp wagon and a team, and, outfitting with a liberal supply of fruits and nuts, and other "raw foods," we started south through the wonderfully beautiful Willamette Valley.

With two cameras and hundreds of plates we expected to have an interesting

pictorial record of our trip, with a special eye to any thing connected with bees and beekeeping.

Perhaps the season had been unusually unfavorable through the Willamette Valley; but the honey that we purchased or tasted along the way was probably the vilest concoction that a bee was ever forced by dire necessity to store in waxen cells. Through the whole length of that beautiful valley, not one apiary, of any considerable size, was seen or heard of, though at one place we found the young lady of the house quite up to date, and purchased two sections of so-called "maple honey," of light greenish color and delicious aroma; but, alas! to my taste at least, it was of very inferior flavor.

A shed apiary, typical of those found in the Willamette Valley, Oregon.

The little shed apiary here illustrated is, perhaps, a typical Willamette Valley beeyard. The sheds roofed with old split cedar shakes serve to protect the hives from the excessive winter rainfall.

The hives are about like an eight-frame Jumbo of extra depth, taking the regular eight-frame super, while their occupants are usually of the large brown German type, or hybrids. At Woodburn, inquiry for C. T. Bon-

A sample of how bees can be made to spell. See Mr. Arthur's letter.

ney, at one time a contributor to the *Review*, revealed that he had removed to Arizona.

Passing over minor ranges of mountains, rich with fern and vine, we arrived in the Rogue River Valley, where alfalfa is common, and great orchards ship trainloads of the finest fruits to the world's markets.

At Central Point we found an up-to-date beekeeper and rancher, and here replenished our supply of alfalfa honey.

Inquiry at Medford revealed the presence in that community of another beekeeper having 200 or more colonies; but as we were unable to find him we left between showers for Ashland and the summit of the Siskiyou Mountains. We waited two days at the base of the mountains for the rain to cease, and then made the climb without difficulty. Down long grades, through green ravines and valleys, here and there a little field of alfalfa brightened the eyes of the travelers until, in Siskiyou Co., California, we pulled up one night at a farmhouse where about 100 two or three story hives adorned the landscape. We spent the night with good Mr. and Mrs. Brown, discussing bees and locations, pictures and climate, until a late hour.

Near Kalamathon we found a dilapidated apiary where once some old bee hermit held forth, but now far on the road to extinction.

At Chico, where, a few years before, the government had stationed John M. Rankin,

with a government experiment apiary, we expected to revel in good bee talk again; but, no. A long walk to the government gardens showed us that the bees had been sold and the work abandoned.

At Nicolaus, seedy and forlorn, the home of the carpet grass, formerly the home of the Tyler Brothers, bee kings of Nevada and California, we met a beekeeper of some 500 colonies who was about as communicative as a clam; so, after sampling the honey of the region at the corner store, we went on our way.

We ended our trip at Sacramento, as the winter rains made travel any thing but pleasant.

As a whole it seemed to us that the vast territory from Portland to Sacramento was about as poor bee-territory as could be located on the map, with here and there a little oasis where fair crops may be had.

After a few days at Sacramento I took the train for Idaho, while Mr. Dilatush went on by train to the sage and orange apiaries of the South.

Meridian, Idaho, Jan. 25.

[In 1901 we went over that same territory, and our conclusion was that it was by no means the equal of the central part of California nor yet the southern. We are not quite prepared to believe, however, that it is poor territory, for we believe that, when population increases, some fine bee-ranges will be found.—ED.]

BEES THAT CAN SPELL

BY J. WARREN ARTHUR

Under separate cover I am sending a photo of the honey that I exhibited at our fair last fall. Some two or more years ago you spoke of bees robbing from carloads of honey shipped to you, and you said it seemed as if the bees could read the words "Big Four" on the car. Ours can spell. We call our home "Cozy Nook," and the bees spelled it out without trouble when I gave them the copy. The C and Z were slightly crushed, and were bleeding, which shows somewhat in the photo. The Z was not capped as white and pretty as some of the others.

Springfield, O., March 6.

[There are beekeepers who can make their bees "spell" if they only know how. Perhaps our correspondent will be willing to explain how he did it. In the meantime we should be pleased to receive short articles from others on how the trick is performed.—ED.]

A FAMILY OF EIGHT THAT EATS FIVE POUNDS OF HONEY A DAY

BY DAVID E. DOBBS

I believe I am the pioneer beekeeper of Koochiching Co., Minn., which is about as far north as one can live in the United States. I was born in Brown Co., Ind., in 1871, and became interested in bees in 1881.

My father had kept bees for years, but in box hives. At this age I induced him to buy some Italian bees and movable-frame hives. He told me he expected me to take care of the bees from that time on, so you may be sure that pleased me. I was the youngest of five boys of my father's family. I was married when 25 years old, and now have five boys and one girl.

I kept bees continuously until 1902, when my family and I started for Northern Minnesota, where we took up a homestead in the wilderness, where there were lots of moose, deer, wolves, and mosquitoes to shoot of which I had my share. We had lots of hardships in this country; but in 1908 I bought a colony of bees of F. A. Gray, of Redwood Falls, Minn. I received them May 12, after a confinement of about 15 days. That year I increased them to four colonies and took 200 lbs. of honey, and wintered them without loss. In 1909 I increased to 17 full colonies, but took only 125 lbs. of honey, and had to feed 300 of sugar. I again wintered them without loss, so that in 1910 I commenced with the 17 and took 3000 lbs. of extracted honey, or over 176 lbs. per colony, and increased to 34 colonies. In 1911 I commenced with 34 colonies and took 7000 lbs. of honey, of which 6000 was extracted and 1000 comb honey—an average of over 200 lbs. per colony, and increased to 69 colonies.

My honey that I have sold has averaged me 14 cts. per lb. We believe in practicing what we preach, as we use about 5 lbs. of

A steam melting and rendering outfit for old combs. See next page.

David E. Dobbs and his family of "consumers" who, besides helping to produce honey, eat five pounds of it a day.

honey per day, and have it at every meal.
Indus, Minn., Feb. 24.

[Five pounds a day! That comes pretty near if not quite up to the high record of daily family consumption of honey. We should like to inquire if there is another family that can beat it. The families that are large consumers of honey appear to be healthy people. Aside from the sweets in fruit, honey is the only sweet available to man without special treatment. We know that the sugars in fruits are healthful and nourishing. In the same way we know that honey is equally so; but because it is more concentrated, a less quantity can be taken at a time.—Ed.]

A STEAM-BOILER OWNED BY THREE BEE-KEEPERS FOR RENDERING OLD COMBS

BY P. H. BALES

I am sending you a picture of our wax-melting outfit which has given us such good satisfaction that it may be of interest to others. Two of my neighbor beekeepers went in with me so the expense was not much for any one of us.

The outfit consists of a steam-boiler, a steam reservoir, or tank, and a Root wax-press. The tank is 6 ft. long, 20 in. wide, and 22 in. deep, with a screen 11 in. from the top to hold the old combs that are melted by steam from the pipe just underneath,

which is perforated the full length of the tank. The steam is turned into this pipe, and it strikes the screen from below. There is room for the melted wax below the pipe, and a faucet in the bottom of the tank for drawing it off. The lid fits tight.

The wax-press is attached to the boiler; and any amount of steam can be turned in at will. We now have the whole outfit in a tight room to keep out bees.

Hanford, Cal., May 3.

[There is nothing that can be compared to steam for heating water or for cleaning wax or propolis off from articles used in the apiary. Steam can not heat water enough to do any damage to wax; and where a beekeeper can have access to it he is much more fortunate than those who have to depend on stoves or outdoor arches. Usually it is not practicable for the beekeeper to own his own boiler, as the amount of use he can get out of it would not warrant the first cost. Small boilers can usually be obtained at an expense of from fifty to sixty dollars.—Ed.]

PROOF THAT BEES THIN DOWN THE BASE OF COMB FOUNDATION

BY JOSEPH H. PETERSON

I have often seen the statement that bees seldom or never thin down the bases of cells in foundation; but of late in examin-

ing combs I have noticed some very marked examples that seem to contradict that statement. I have had my partner, Mr. A. H. Wileox, take a picture of one by transmitted light, which shows, although somewhat imperfectly, the very noticeable difference mentioned above.

At the lower left-hand corner, where the wire is fastened, is a three-cornered patch of the original foundation. Next is a smaller patch of partly drawn and thinned-base foundation. The rest of the picture shows varying degrees of drawn comb, all of which has the base reduced to a very thin transparent condition. At the upper right-hand corner the cells are deep and slanting, so that the camera could not look directly into them, as was the case in the rest of the picture.

The foundation used in this case was home made, running about $6\frac{1}{2}$ sheets to the pound.

Ogden, Utah, March 11.

[Your last sentence explains why your bees thinned down the bases of the foundation. Six and a half sheets to the pound virtually makes what we call "heavy brood" foundation. When the base is thick, as it is in such sheets, bees will, as a rule, thin it down; but when ordinary super or extra-thin super foundation is used, the base is so

near the thinness that we find in natural comb that they generally leave it without alteration. Mr. E. B. Weed, the inventor of the Weed process foundation and the machinery for making it, conducted numerous experiments years ago, the result of which showed that, when the base of foundation is almost as thin as the base of natural comb, they will not alter it; but, no matter how thick the *walls* of heavy foundation are, they will thin them down to the natural thickness—3-1000 of an inch.—Ed.]

BEEKEEPING FOR WOMEN

BY AVALVE C. ROBBINS

Sister Beals, of Lewiston, Me., has broken the ice. I too have three nice colonies of bees. I buy my inside fixings by the hundred in flat, and so have the same enjoyment of pounding the nails (not fingers, for all women do not pound their fingers).

I had been looking for some time for a business whereby I could be at home and attend to my wifely duties and still feel as though I were earning some money. So my husband finally invested about \$33.00 for me, and I find beekeeping just the thing. I will succeed or "bust."

The lower left-hand corner shows the original foundation. The lighter portions show how the bees thinned down the base.

I have hived two swarms this week, following expert Alpaugh's method with the dishpan and sheet, with very good success indeed—no stings at all, and five hives in stock.

Why don't more women keep bees?

You know they say a woman is determined to have the last word. It is my opinion that, if more women would show their determination in beekeeping, there would be more peace and harmony in our world.

South Berwick, Me.

SEVEN "OUTDOOR" COMBS, 15 INCHES WIDE AND 2½ FEET LONG

BY HARRY HEWITT

I commenced keeping bees only a year ago, taking up wild swarms, which seem to be quite plentiful in this section. I found 19 bee-trees last summer.

The other day I made a unique find which may interest you. I found bees feeding on huckleberry blooms, and I "lined" them 1½ miles before finding the swarm. They have made their home among the top branches of a small oak, about ten feet from the ground. The combs, quite exposed, are about 2½ feet long by 14 or 15 inches wide, and the bunch is about seven combs thick. I should judge the nest to be quite a year old.

Apopka, Fla., Jan. 29.

"Outdoor" colony in Florida that have lived in these exposed combs over a year.

REPORT OF THE SEASON AROUND CINCINNATI

How the Large Acreages of Sweet Clover were Made Available for the Bees

BY HENRY REDDERT

On page 430, July 15, I notice the honey report up to July 9. No report being included from this district I will try to give as accurate a report as possible.

Up to date (July 18) sweet and white clover are still in full bloom. It rained here every day this month except one. Clover began blooming about June 15, and on June 20 it was in full bloom. The bees have worked every day since; and, according to present indications, clover will bloom this entire month and into August. New bloom is forming as fast as the old goes to seed. Fruit bloom, locust, dandelion, Chinese aster, all were good forerunners of the clover yield; and beekeepers having strong colonies this spring will harvest a heavy crop.

Under the above conditions bees built up strong, and swarmed heavily at the beginning of the season. Mine began swarming the last week in May, and kept it up two weeks in June. All the swarms will give a surplus. Besides, the parent colonies built up strong after swarming, assuring a heavy crop. All the beekeepers I came in contact with inform me the same conditions prevail in their apiaries. However, there are some heavy winter losses, due to the scant honey crop of last season: One man lost 30 colonies out of 90; another, 37 out of 40, having but 3 left. This last named may also have had disease; but I can not verify it, as I have the report second hand. We all lost more or less; but the above named are among the heaviest losses.

There are many people in the bee business with very little theoretical experience in the beginning of their career, making success impossible, and dangerous to their neighbors. These, of course, will have no heavy yield to report—probably none; but, taken as a whole, we have a good honey year for those with good healthy colonies.

Sweet clover has had a bounce year. All the hills and valleys are covered. Some people cut it down (but not many) about June 10; but I notice that some clover is now in full bloom. We petitioned our Mayor, Henry T. Hunt, to request the council to see to it that the sweet clover be saved when the weeds were cut. Before he sent our letter to the council, he gave it to the reporters of the daily papers. The next day it appeared in every paper, Eng-

Warner's flat covers roofed with painted tin.

FLAT TIN COVERS

Their Use in New York

BY L. G. WARNER.

Our apiaries, two in number, consisting of 301 hives at present, are situated in the pleasant and fertile Schoharie Valley, about $1\frac{1}{2}$ miles from the village of Middleburgh, N. Y. Our honey sources consist of the numerous wild plants and trees usually found in a hilly country of this latitude—some fruit trees for spring brood-rearing; clovers — alsike,

lish and German alike, and I noticed in the suburbs where people cut their lawns short at intervals heretofore, most of them are now in full bloom. "A stitch in time saves nine;" also saves the honey for the bees. However, tons of honey are going to waste for lack of bees.

The beekeepers of Hamilton and Butler counties are making efforts to make a display of bees, honey, wax, and bee supplies at their respective county fairs this fall. The Hamilton County Fair will be held at the Carthage fairgrounds, August 14 to 17. Our association will hold a special meeting for this purpose the last Monday in July. All members are invited to take part in this, our first attempt at public display of bees and their products. The meeting is to be held at the headquarters, 2146 Central Ave., Cincinnati, O., at 7:45 P.M.

[We will explain to our readers that Mr. Henry Reddert is a "live wire" on the subject of bees—and, moreover, he seems to have in mind the greatest good to the greatest number. We believe it is largely through his influence that sweet clover has been made available to the bees in and about Cincinnati. Of course, he has a beekeepers' society back of him, and there is the secret. City fathers and legislators will listen to a request from an *organized body* of men when they will utterly ignore the request of an individual. What the Hamilton Co. Beekeepers' Association has been able to accomplish, others should be able to do. It only needs one "live wire" to stir up the rest to action. Does that mean you, dear reader; and are you looking after your county fair?—ED.]

white, and sweet, in their season (when it is favorable), and buckwheat for a fall crop.

The acreage of buckwheat some years is very satisfactory, depending on the amount sown by the surrounding farmers. The past year, weather conditions were unfavorable, so all we could do was to look at the bloom, and—*wish*. Goldenrod and wild asters sometimes provide a late sustenance, but can not be relied on.

We produce mostly comb honey, using a hive taking eight frames and dummy. The hive is $18\frac{1}{4}$ inches long, $14\frac{1}{2}$ inches wide, and $11\frac{1}{2}$ deep. Our hive-covers, as shown in the photograph, are flat, having a two-inch rim all around the under side to prevent rain from driving in; also to prevent their being easily blown off by the wind. The entire top and about half of the width of the rim is covered with a sheet of well-painted tin. All of our hives and covers are painted white, as we think they last enough longer when painted to pay, regardless of the improvement in looks. This cover has been adopted after years of experiment with box tops, flat boards, covers with end strips, and others.

In connection with these covers we use an oilcloth or other heavy bagging cloth over the frames or boxes to prevent the cover from being glued down with propolis, this facilitating handling the bees without needless jarring when opening the hives.

Middleburgh, N. Y., Feb. 8.

[The style of telescoping covers shown in the illustration with a thin super cover beneath are becoming more popular.—ED.]

A NUMBERED STAKE IN FRONT OF EVERY GROUP OF THREE HIVES

BY J. W. SOUTHWOOD

Louis H. Scholl, in the May 15th issue, calls up the question of hive numbering. It may be true that what is satisfactory to one may not be to another. Yet what is satisfactory to one may be of benefit to others, even if not entirely satisfactory. With this thought in view I will give my method of numbering hives, which has proven, after several years' test, the most

satisfactory of any that I have tried, and I have tried several others.

My hive-stands are a little more than six feet long, and hold three hives, one at each end and one in the middle, all facing the south. About two or more feet in front of the middle hive of each group of three is placed a stake which is painted white. These stakes contain the numbers in black or blue figures. In order that the figures may be larger, they are arranged so as to read vertically if more than a single figure is used to express the number of the colony.

J. G. Corey, of Santa Paula, Cal., in his 84th year—the man who, years ago, carried a colony of bees over 100 miles across the mountains, making a part of the trip on snowshoes. See department Our Homes, by A. I. Root.

These stakes are square at the top, and are an inch and a half or more in diameter; and when set in the ground they project ten or more inches above the ground. I commence at the northwest corner and number across one row of groups, and then go back to the west and number across another row, just as one would do in reading a page. On the west side of the first stake is No. 1; on both the north and south side is No. 2; and on the east side is No. 3, and so on with each group. With this arrangement a person soon learns the location each number occupies. The number designating the middle hive of each group contains the number of the colony, both on the side next to the hive and also on the opposite side of the stake. By this arrangement a person standing in any position in the apiary can see one or more of the numbers of the group, or a group next to the group which it is desired to notice. If desired, the stakes can easily be moved while mowing the aisle, and then set back in their places.

I purchased a blank book of sufficient size, and numbered the pages up to the number of colonies in the apiary. Then each year I make the date of the year and then make a record of each colony, whatever is desired. When clipping queens during apple bloom I note whether the queen is old or young, and the condition of the colony as to the strength and amount of stores. I also record when special queens are given, etc. As I hive the swarm, when permitted to swarm, on the old stand, or if I use the Alexander method, somewhat modified, of making increase, the old queen always remains on the old stand unless, for some other purpose, she is changed; then a record of the change is made. With this method I can readily refer to any number desired, both in the book and also in the apiary.

When several colonies alike are requiring attention I place the numbers on a little board and put it in my tool-box, where it is convenient.

Huntington, Ind.

[Like Mr. Southwood we favor putting hive numbers on stakes rather than on the hives. At our home yard, a substantial hard-wood stake with cross-arms on it supports the grapevine which stands just in the rear of each hive. Our hive numbers will be found about two feet from the ground, tacked to the north side. The advantage of this arrangement is that the hive may be shifted about, leaving the numbers right where they should be found. When numbers are attached to hives, and it becomes necessary to move any particu-

lar hive, the number tag must be removed or else it causes endless confusion in trying to find that particular hive number out of its regular position. When the apiarist goes through his yard he can make his records on a card index.

At the present time, however, we are using a scheme of wooden tablets for records on the hives. But we still use numbers to designate places where certain queens, brood, or other material may be found. We will illustrate this scheme a little later.

One side of the wooden tablet is painted red, and the other white. The latter holds the record in leadpencil. When the former is turned outward it shows that the colony needs attention. The wooden tablets are held in place on the side of the hive by means of brass spring clips.—Ed.]

HIVE FOR USE DURING A TIME WHEN ROBBERERS ARE BAD

A Bee-cage Designed to Fit the Top of the Hive

BY LANE S. LEONARD

Every beeman knows what it is to open hives and work with bees when honey is scarce in the field, and surrounding bees eager for robbing; yet various things often make this unavoidable. Where hives stand on benches or on the side of a hill, or close together, a bee-tent is out of the question. Careful management at such times often deluded me into the idea that, in spite of the annoying robbers, I had little or no loss by them; yet by the next morning many (sometimes very many) dead bees would lie in front of the hives where I had worked.

To overcome the trouble I constructed what, for the want of a better name, I call a bee-cage. It is about 3 ft. high, and a little over 2 ft. wide. The operator, who stands at the back of the cage, is shielded by burlap tacked on the rear of the top and rear edges of the sides and bottom. It is designed to rest on top of the hive or on the super after the hive-cover is removed. The bottom of the cage is provided with an opening to match the opening of the hive, so that, when the cage rests on top of the hive, the opening in the bottom fits snug and even with that of the hive; and, being wider than the hive, it affords sufficient room and unobstructed access to the frames, and enables one to handle them at will. A bee-escape is arranged at the top so that any bees that crawl up the screen will find their way out.

The cage being made of light half-inch boards, with wire gauze for the front and sides, is easily handled, especially after a

little practice in handling it; but as it is to be used in troublous times a person can not be too careful not to have the hive entrance unduly large and not to puff smoke on the guards at the entrance, for they may soon be needed there. If there is an inside as well as an outside cover, so much the better, assuming there is only one cover.

We have the smoker ready, and also a clean piece of cloth or burlap to lay over the open hive as soon as the cover is removed; then after the cage is set on top of that, we first tip one end of the cage up to remove that end inwardly, and then tip the other end; then take the cloth away, and not a bee will get in. This done, it is a pleasure to work with the colony or lift out frames. A little puff of smoke on the bees in the hive subdues them. The roof of the cage gives a very agreeable shade, and in cool weather the cage is a protection against chilling the unsealed brood.

[At certain seasons of the year, especially right after a heavy flow of honey, and when all the nectar supply has ceased, robbers are particularly troublesome. At such times we find a cage very convenient, and at times indispensable. The form of cage that we use, however, is made of a light framework of $\frac{7}{8}$ -square strips covered with cheese-cloth. This material is not only cheaper but better than mosquito-netting or even wire cloth. If it becomes torn it can be very cheaply replaced. But why is cheese-cloth better than mosquito-netting? Mainly because it cuts off from the robber bees hovering on the outside all view of the operations inside. This, we have dis-

covered of late years, is very important; for when the bees can see the combs exposed they are much more inclined to hover around the cage than when the vision is cut off by cheese-cloth.

The tops of our cages have no cover of any sort, and hence no bee-escape is needed. The average beekeeper would suppose that a top would be indispensable to keep out the robbers; but as a matter of fact they will not dive down; and if they hover around at all it will be about two feet from the ground, or about the level of the top of the hive. The bees that fly up when the hive is being operated, readily escape; but no outside bees will dive down into the inclosure where the operator is quietly at work free from molestation. The cages that we use are 5 feet high, 3 feet 6 inches wide, and 4 feet long. Two feet from the bottom are two side rails, $\frac{7}{8}$ square, which serve as handles to enable the operator to lift the cage off the ground, walk over to another hive, and "squat" over it.

We have never tried an arrangement like the one here shown; but we would consider it more difficult to adjust over the top of a hive than one of a slightly larger size and lighter construction—one that could be set over the entire hive and still leave room for the operator. One objection to the Leonard cage is that it would fit only one style of hive. Where double and single walled hives are used, as in our apiary, especially if some of them were eight frame and some ten, it would not be practicable. Then it occurs to us that the curtain work at the back of the operator would have to fit closely around the ground and close to the hive to prevent robbers from getting in. The cage that we have described rests on the ground, and the grass makes it practically impossible for robbers to get under. As a matter of fact, they are not much inclined to crawl through obstructions.—Ed.]

There has just come from the press a new bee book entitled "The Tunisian Beekeeper," by J. Georges, Chevalier du Merite Agricole, an officer of the Nicham Iftihar, President of the Apicultural Society of Tunis, and teacher at that place. The price of the book is 60 cts.; by mail, 65 cts.; 12 copies for \$5.62. Send remittances to Mr. J. Georges, 150 rue Bab Souika, Tunis, Africa.

Heads of Grain from Different Fields

Laying Workers and How to Treat Them

One year ago in June I purchased a two-frame nucleus. This spring I clipped the queen. About the 10th of June they swarmed, but we did not see them till they were going back in the hive, nor did we see the queen on the ground. The next day I found the queen at the entrance dead. I do not know whether she did not get back, or they killed her and carried her out.

Ten days after a large swarm came out and clustered I set a new hive near them with full sheets of foundation, and they rushed in. I then set the old hive aside and put the new swarm in their place.

Ten days after I looked at them they had drawn out all the comb and stored considerable honey on the outside of the frames. I have not found any brood in either hive since they swarmed.

About the 20th of June I bought two queens—one for each hive. The bees were about 30 hours in eating out and releasing the queens. They killed them both at once. There is but very little brood in the old hive. By the appearance there are several eggs laid in one cell—each looks very large, acts like a laying worker. Is there any thing I can do to save the bees? Must I let them die, and start over again?

F. B. FENNER.

Vineyard Haven, Mass., July 13.

[From the facts given in your letter it seems apparent that the queen of the hive was lost when the swarm came out the first time. Either her wings were defective so she could not fly, or she was clipped. In either case she failed to get back into the hive. But if that be the case it is a little strange that they should not have had a number of swarming cells in the hive. One of these should have supplied a virgin queen, and you should have had a laying queen in the colony. If a virgin hatched from a cell she failed to mate, or was probably lost on one of her mating trips. This would leave the hive queenless. A queenless colony will develop laying workers in a course of two or three weeks. Therefore a laying-worker colony will not accept a laying queen. At least we can set that down as a general rule that has exceptions. When you attempted to introduce the queen that you bought, the laying-worker colony probably killed her, and left it in as hopeless a condition as before. The fact that you find more than one egg in a cell is pretty conclusive proof that there must be laying workers in the hive. They are very hard to get rid of, especially for a beginner. You might try giving them a ripe queen cell from some other colony if you can secure one. Sometimes a vigorous young virgin, after she hatches, will be accepted; and if she is she will clean out the laying workers, or at least the bees do so.

Very often, and we think we may say generally, the giving of a cell is only a little better than the giving of a laying queen. If you have other bees, scatter the brood and bees in other hives and break up the colony altogether—that is, providing the giving of a cell does not work.—Ed.]

What is the Advantage of a Large Smoker?

I once thought a larger smoker would probably give me better service, first, because it would give me more smoke; and, second, longer service with one filling. After using a Jumbo I find that it *does* give more smoke, but altogether too much—more than half of it is wasted. During all the time I used the smaller smoker, I never saw the time when I did not have all the smoke I needed. What is the object of sending out a great volume of smoke when a small stream will answer all the purpose? And if a larger smoker produces more smoke, it also uses more fuel; and if it uses more fuel it burns out faster, and, consequently, will not last any longer with one filling than a smaller one.

Since I use the larger smoker I use twice the fuel I did with the smaller one. To be sure, the amount of fuel used is practically valueless. But we are not all so fortunately situated that we can any time step into a machine-shop and help ourselves to all the greasy waste we need. Some of us backwoods fellows have to depend on something else. I am surrounded by old apple-orchards, and have to resort to rotten apple-tree wood for my smoker material. This, too, has no intrinsic value; but, after all, dur-

ing the past twenty or thirty years I have spent quite a little time in gathering and preparing my fuel; and if I have to spend twice that time on account of a larger smoker, the latter would be an actual damage to me or to anybody who uses it.

La Salle, N. Y., June 15.

G. C. GREINER.

[A small smoker will give nearly as much smoke as a large one, or it will give as much as any one would ordinarily need in going over his hives. The chief merit of a large smoker rests in the fact that it will take a larger amount of fuel, and will, therefore, run longer without refilling than a small smoker. Where one burns comparatively large chunks of firewood, rotten wood, or any kind of bulky fuel, the large smoker with a big barrel is much more suitable than the small one. As a rule, extensive beekeepers use the large sizes, and the smaller ones the smaller ones.—Ed.]

A Bunch of Questions

1. Can I use $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$ sections in the same super where I have used $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$?

2. How can I get the queen out of the super? Can I use a bee-escape?

3. How can I stop a bad case of robbing?

4. Which is the best cover—the single-thickness board cover or the metal cover with inner cover?

Fosston, Minn., June 26.

SUBSCRIBER.

[1. The $1\frac{1}{2}$ -inch beeyaw sections require different fixtures, such as section-holders, separators, etc., than the $1\frac{1}{2}$ -inch plain sections; but if you have the fixtures to go with them you will not have much trouble in altering the super so as to take them.

2. About the best way to get a queen out of a comb-honey super would be to take the sections out one by one until you find her and carefully lift her off, and put her on one of the combs below. If you simply put a bee-escape between the super and brood-chamber, it would not work very well; for if there is any brood in the super the bees probably would not go down below and desert it, nor would the queen be likely to go below through the escape. Very few queens give much trouble by going up into the comb-honey super; and rather than use queen-excluders for a queen that is inclined to do so it would be better in the end, probably, to require.

3. There are a good many ways of stopping robbing; but one way where robbing has not progressed very far is to throw a bunch of wet grass over the entrance of the robbed colony. Another way is to exchange places between the robbed and the robbing colony. Still another and the best way is to carry the colony being robbed to a cellar for a day or two, then carry it back after contracting its entrance.

4. We regard the metal-covered telescoping cover with super cover underneath as about the best cover, all things considered.—Ed.]

Large Reported Honey-yields

Some time ago I wrote you, stating I thought 500 or 600 lbs. of honey per colony too high an estimate. You replied you would not let any such statement be published, as that would be impossible; yet on page 297, May 15, Mr. Chadwick tells of an entire county averaging 700 lbs. per colony. Why did he not say a thousand, and make it sound more like it? A man in this locality obtained 500 lbs. from one colony, and people wondered how it was done. Come to find out, he put all his swarms in a dry-goods-box, hence results. Now, you might have fifty swarms in a box car and have them fill it, and then write it up for GLEANINGS and have something worth while. It takes a large piece of fat pork to make me swallow these tales.

WALTER C. BENNETT.

Frankfort, N. Y., June 17.

[Well, friend Bennett, it looks as if you had us where the hair is short. We shall have to back down and acknowledge that perhaps you have the laugh on us. On p. 486, Aug. 1, you will see where Mr. Chadwick explains the figures of large yields. We may say incidentally that California bees and California climate, with the right kind of management, and good seasons, will sometimes do wonders. We might say the same thing of New York State. However, it is our general policy to

fight shy of statements of large yields—not because they are not true, but because they are so much above the general average, one year with another, that the general public is a little inclined to be like you—they want “a large piece of fat pork” in order to enable them to swallow such tales. Come again, Bro. Bennett, or anybody else who finds that GLEANINGS is inconsistent with itself.—Ed.]

Introducing Cell at the Entrance

I have great pleasure in reporting an idea (result of an accident) which sounds the death knell to queen-cell protectors. My nephew, R. J. T. M. Muckle, a most enthusiastic beekeeper, going to introduce a queen-cell, found nature had endowed him with only two hands; and as he was using a smoker, and had to remove cover, etc., he found them inadequate, so he laid a cell on the entrance-board while doing necessary work. He noticed that there was a scramble of bees at once over the cell, so hurried to the place where intended. Next day he found the cell firmly fastened in place, and all right. As he had had several cells torn before, he advised me to try the plan.

Now, I had a colony that would not accept a cell, even digging under a wire cage imbedded in the comb to destroy, so I followed the youngster's plan of leaving it at the entrance for not over two minutes. When putting a drop of honey on the point of the cell I placed it, and all was well. I have done several others, and with the same results.

A grand season is 1912, as was 1911; but there has been no failure since I came to Manitoba in 1870. ROBT. J. T. MUCKLE.

Clandeboye, Man., July 15.

[The idea of putting a queen cell in at the entrance of the hive has been before mentioned in these columns; but we can not recommend it, as such a cell is very easily chilled; and the baby queen inside of the cell, if it comes too cold from exposure, will be seriously injured. She may be able to hatch out, become mated, and lay eggs; but as a general thing such queens are short-lived. Perhaps in extremely warm weather the occupant of the cell would receive no injury.]

We may say in a general way that, in most cases, the queen cell may be inserted right inside of a queenless hive, without protector of any sort, and the bees will not tear it down; but because there is danger of their doing so, we advise putting cells inside the protector. The protector not only prevents the bees from gnawing holes in the cell, but it prevents it from being crushed in handling. When a queen cell is in a protector it can be pushed into the comb and not injured. For that reason, when we give cells we advise the use of protectors.—Ed.]

The More Comb in Bulk Comb Honey, the Better

I have just read Louis H. Scholl's communication, June 15, on bulk comb honey. I have a good demand here in Chattanooga for the bulk comb honey in different-sized packages in glass jars, pints, quarts, half-gallon, and in tin pails, friction tops, 10, 20, and 60 lb. tin cans, and I find in a great majority of cases the more comb the better the customers are suited. I get the comb honey cut from frames packed in ten-gallon kegs and fifty-gallon barrels shipped me from Mississippi, which comes in good condition when packed close with comb and filled in with extracted honey. I have received a few packages which were not properly packed, and arrived in bad condition.

As stated, comb honey is lighter than extracted. The most of my patrons are very particular to have full weight exclusive of containers. My principal trade is in supplying the retail grocery trade, and they are not inclined to pay for the cans weighed as honey. I am just like them. When I buy a barrel of honey I want the weight of the barrel taken off every time; but they have a custom in the South of selling 13 lbs. for a gallon, and nothing off for the barrel.

Chattanooga, Tenn., June 24. G. E. LEAVITT.

To Tell which Hive Cast the Swarm

My way to tell which hive the swarm comes from is this: I hive the swarm as usual except about a cupful of bees, and take it to the further side of the apiary, or cover it up with a cloth so the bees left can not find it. Now, if these bees do not take wing

readily I smoke them. Then I look over the hive entrances, and, seeing one with bees standing with buzzing wings and abdomens sticking up instead of down, as ventilator bees do, I know that *that* is the hive. I have located about fifteen such swarms this season, and several last year, in an apiary of 120 colonies, often finding their hive in five minutes.

I have caught a good many stray swarms by putting out decoy hives.

When I was attending public school I put a hive under my buggy-seat and took it to school every day. (I did not know then that I could carry a swarm home in an old sack.) Well, a swarm took possession of this hive one day, and I took it home without taking it from the buggy!

Lakeside, Cal., June 3. G. E. PHILBROOK.

The Tupelo Tree as a Honey-plant

A subscriber sends us the clipping below, which he says was taken from the *Florida Grower*:

I want to find a good location for an apiary where the tupelo tree grows plentifully; also want it where there are some large orange-groves near by. Some of your subscribers may know of such a location.

Stuart, Florida.

E. S.

[Note.—Perhaps some subscriber can answer this question. We have never heard of the tupelo tree before; and in a list of over 300 Florida trees this name does not appear.]

There are some very successful apiaries in Manatee Co., and along the west-coast keys.—Ed.]

[The above illustrates how poorly some editors are equipped for giving information. On pages 596 and 597, Oct. 1, 1911, J. J. Wilder describes and illustrates the tupelo; and it is also illustrated in the last paragraph on page 374, June 15, this year. I have just interviewed Mr. Marchant, our apiarist, and he says that in Northern Florida, where his father is located, they have taken out as much as 100 tons of tupelo honey, and the tupelo tree is thickly scattered over a region of 100 square miles in Northern Florida. If I am correct, there is but little or no tupelo in Manatee Co.—A. I. R.]

Why Winter Bees at the North?

I agree with some of the imaginings put forward by your anonymous writer on p. 307, May 15, for I was arguing similar ideas with my brother the day before receiving our copy. I can sympathize with his wish to remain anonymous, for I found that unorthodox suggestions are not always gratefully received. I protested there was need for imagination in beekeeping as well as in science. I suggested what I termed a more free treatment of bees, somewhat as follows:

Our grandparents set 13 eggs under a hen, brooded the chicks under the hen, and seldom transferred them far from home. Now we send eggs miles away, incubate them by hundreds, rear in brooders, and have a big trade in day-old chicks. Bees are conservative things (they reject new queens, they resist uniting, and they refuse to be changed in position); yet is it not possible to adopt a similarly free treatment of bees?

When, suppose, the only honey-flow of a district is an early one, or early because of being in the South, why not, when it is over, catch most of the flying bees which then become consumers, and a nuisance in the apiary (I used to suggest destroying them), and sell them to be hived on foundation in a district where there is a later flow? They might be fed on sugar for about three weeks before the flow commenced. One can imagine bees being transferred once or twice during the year, and some of the keepers keeping them for only about two months of the year, while others keep them all the year round and rear them in large quantities to supply those who don't.

Why so much cellar wintering? Why not buy bees by the pound from the South, where they may be reared in large quantities? Why not the price of bees by the pound be given in the daily paper like that of other commodities? One can imagine a big yearly trade or seasonal migration of bees, with local importers and exporters. Why shouldn't they be transferred from south to north, and from one honey-flow to another? Why shouldn't a beekeeper, if the honey-flow of his district is of short duration, whether early or late, if he does not want to keep bees all the year round, double or treble such re-

cently hived stocks under one queen as soon as the flow commences, so as to liberate a big gathering force, and so as, when the flow ceases, he will have comparatively little brood, and few bees to sell or destroy? Then extract from all the frames, making no distinction between brood and super, and melt the wax and put away the hives for another year. Some would never need supers, and yet produce large quantities of honey and wax. Whether one dequeened and doubled, or continued to produce bees to the end of the flow, would depend upon the market price of honey as compared with that of bees. Thus we might revert somewhat to skep methods, combined with the movable frame and tiering crate. Foul brood would be unable to exist.

Beverly, Eng., June 20.

T. T. TAYLOR.

[See Editorial.—Ed.]

Worker Bees of Normal Size Reared in Drone-cells

Some time ago there was some discussion about large bees. Some one wanted to renew the combs each year, and some one said use drone-comb foundation and the bees would all be large ones. I did not use drone foundation, nor did I intend to experiment along the line of raising big bees. It happened that I used inch starters in some frames last fall for bulk comb honey. The bees made drone comb of them all, 9, and did not finish them nice enough for comb honey, so I let them stay on the hive all winter.

This spring, while working with the bees, I found a whole body of 9 combs full of drone brood, as might be expected. A few days later, I was looking for queen-cells, when I accidentally uncapped one of those drones; and to my surprise a worker bee walked out. That put me to looking and thinking, so I uncapped some more of them, and they were all worker bees, and, to my eyes, they were no larger than those raised in common worker cells. I used some of this brood with brood from other hives to make some nuclei, and do not see any difference in the bees. The little workers looked lonesome in those big cells.

Lane City, Texas, May 11.

W. H. MOSES.

[Numerous cases like this have been reported in times past. We may safely say that enlarging the cells in order to rear larger bees is an old exploded theory; and yet every now and then some beekeeper gets it into his head that he is going to be able to rear larger bees, and he wants the foundation man to furnish him cells slightly larger than the worker. It has been proven that old combs do not produce smaller bees than new ones. See what our correspondent, Mr. Gardiner, has to say.—Ed.]

Do Young Bees Take up All the Room in the Cells?

Just a comment on Dr. Miller's Straws, p. 262, May 1. If a man faced the south you would have no difficulty in telling which was his right side. Why is a hive different? Those who claim that old combs make small bees must think that the cell fits the bee like tight. As a matter of fact, does any young bee in a cell ever entirely fill it?

Geary, Okla., May 27.

N. FRED GARDINER.

[You are entirely right, friend Gardiner. Any one who has old combs, even though they may be thirty or forty years old, would do well to keep them, if they are free from disease, are perfect, and providing he is not running for choice extracted honey of light color. Many beekeepers believe (and there is some ground for their belief) that old combs have a tendency to darken extracted honey.

But the internal diameter of old combs is never reduced beyond a certain point; for when the cells are a little too small, the bees will remove the excess of cocoons, says Mr. Cheshire, so that the baby bee will have room in which to grow to normal size.—Ed.]

Disease Instead of Poisoned Brood

In the spring of 1910 a large apple orchard in this neighborhood was sprayed, and at that time part of the trees were in blossom. There were two farmers who had adjoining property, and each had about a dozen colonies. A few days later they complained of their bees being killed by the spray. A while later I chanced to be at the house of one, and examined some of the hives. They were filthy with foul brood, and not a cell of honey in either, so this was not a case of poisoning from spraying.

Now, I am not saying that they can't be killed by spraying, but that a great many thought to be killed in this way are starved to death or else die of disease.

We now have a law against spraying during time of bloom. The penalty for violation of this law is a fine of \$50.00. I think this is a good law, and all fruit-growing States should have a similar one, as it has been proven that it is better not to spray while the trees are in blossom—just before or afterward.

Some of the best fruit in the State is grown at South Haven. The Scalacide cup for the best three bushels of apples was captured for two successive years by South Haven orchardists. I am an apple-raiser, and keep bees to pollinize the fruit blossoms as well as for the honey and the pleasure derived from keeping bees. ROBERT MCLEAN.

South Haven, Mich., June 10.

[There can be no question but that there are some cases like this, where disease and not the spraying liquids is the cause of the dead brood; but we are equally certain that there are other cases where brood is killed because fruit trees are sprayed while in bloom. A remarkable instance of this was in Mesilla Park, N. M., two years ago. Both the brood and the bees died while the spraying was going on; and when it ceased, the loss of both stopped. It may be that some make their spraying liquids too strong; but in view of the fact that there is no advantage in spraying while in bloom, from the standpoint of the fruit grower, there ought to be a law in every State against such spraying, to protect not only the beekeeper but the fruit grower himself from his own folly if he does not know any better.—Ed.]

Three Carloads of Diseased Bees Brought into a Healthy Location

In Butte Co. a man moved in about three carloads of bees from Nevada, and a number of progressive beekeepers found his bees terribly diseased with European foul brood. As this county has been free from foul brood it is time that every county have a good foul-brood inspector. We tried very hard to get one for this county; but the supervisors will not help the beekeeper. They claim it is not important. I hope the United States will enact a law that will compel all States to see that they have an inspector, with deputies in all counties.

I heard that this man has gone into another locality that has no county inspector, just to avoid losing his bees by an inspection. It is time to demand certificates of inspection that are dated not longer than five to ten days prior to entrance to each State or county, and on arrival be inspected again if free from disease. The party should be entitled to a right to enter a desired location.

I sincerely hope to see that a safety valve is put on this industry, as we should be guarded against evils like European foul brood. It will do a great harm to California, now being in the North, by this introduction of bees of Nevada. I hate to think of this, as it places fruit men in a bad place too. I am in favor of stopping this migratory beekeeping if disease is going to be brought in to healthy places.

Chico, Cal., June 2.

S. J. MORRISON.

Queens do Not Use Wings to Balance Themselves when Laying

A. C. Miller, p. 755, says regarding the clipping of queens, "When a queen backs into a cell to lay, her wings slide out over the surface of the comb to balance her. As she starts out the wings materially assist her." This seemed conclusive until I watched a queen lay. Of ten unclipped queens that I have seen laying within the last 48 hours, only one touched the surface of the comb with her wings. She was a very small queen. I do not think she used any pressure of her wings to balance her—at least there was no noticeable flexure of the wings. In three cases the wings did not come within $\frac{1}{4}$ of an inch of the comb; in the other six, not within $\frac{1}{4}$ inch. Several times worker bees came up behind under the wings while the queen was laying, and seemed to look down past her body into the cell, but her wings did not touch the worker bees. All these eggs were laid in worker cells. There was no indication of a balancing action by means of the wings, nor any motion of them. It would have been absolutely impossible for either of the nine large queens

to touch the comb with their wings. I take it that Mr. Miller refers to action of the wings on the comb on which the queen is resting, not the one behind her. It is likely that stunted queens laying in worker cells, or perhaps other queens laying in drone cells may touch the comb with their wings. Neither of these cases seems to have any practical interest.

HARRISON H. BROWN.

La Plata, N. M., May 17.

Ignorance of the Market Value of Honey Lowers the Selling Price

Many beekeepers in this locality do not read a bee paper. A great deal of the honey they bring in indicates this. If they would read some bee journal they would not only be able to produce a better grade of honey but also realize the market valuation of it. As it is, they put it up poorly and sell it on the market for what they can get, as it can not stand shipment. Honey, this season, was selling at 15, 18, and 20 cents per section, according to grade. One farmer brought in 1000 lbs. of this poorly put-up honey, and a storekeeper bought it at 11 cents per lb. and sold it at 15, actual weight. This, of course, made a crash in the price in a place like this. I see no reason why a pound of good clean comb honey should not be equal to a pound of cheese which sells at twenty cents.

O. J. GOODMANSEN.

Little Falls, Minn., Dec. 9.

Coal Oil to Stop Robbing

I want to tell of an experiment I tried to stop robbing. I made two nuclei of four frames each, and set them on new stands near the main yard, with an entrance of about 4x½. The bees were all young, and robbing set in. The robbers were in droves.

I quickly grabbed a handful of wet grass and put it in front of the entrance which I had contracted in the meantime; then I took a paint-brush and a can of coal oil and spread the oil the width of the brush, all around the hive. The robbers came out of the hive loaded, and went back to their colonies; but when they came back they smelled the oil in front of the hive, and then, going around the sides, found it there also. In three hours there was not a robber around these hives, and robbing has stopped throughout the apiary.

Manchester, Tenn.

Will Chickens Eat Bees?

I would thank you very much to let me know whether chickens will eat bees. I asked several people this question, and some said yes and some no. We have chickens and a garden, and I have heard that bees should not be put close to any thing growing such as grass, etc., so the only place left for me to put them would be in the chicken-yard.

Richmond, Va., July 22. DOUGLAS M. STITH.

[As a rule chickens pay no attention to bees. A few cases, and only a few, have been reported where they do so, and even then we suspect they eat fresh dead bees, live drones, and young brood when it is thrown out. If they once acquire a taste for live drones they may eat live worker bees. If any one has positive evidence that they do, let him report.—Ed.]

Flags to Show Virgins which Hives they Came From

After reading William A. Sedding's article on tacking up playing cards above the entrances for sign-boards, I wish to mention a plan I have adopted which has proved very satisfactory. All colonies in Imperial Valley are placed under shades called ramadas, made of brush covering about 12 feet in width, and in length to accommodate from 50 to 200 colonies. The hives are placed at the sides with entrances facing out, in straight rows. Naturally, the hives being uniform, and being placed evenly in rows, a great number of virgins are lost unless some distinguishing sign or mark is made.

I take a lath and fasten it lengthwise on the cover with a projection of from twelve to eighteen inches over the front of the hive. On the end of this I fasten a piece of cloth, forming a flag. The virgin locates her hive by this flag, and hardly any are lost.

El Centro, Cal., June 24.

A. F. WAGNER.

To Get Combs Built to the Bottom-bars

I have found that the half-inch bottom-bars mentioned by Fritz Bohne, p. 339, June 1, do not always result in having the combs built clear down to them. I am going a step further and putting a line of melted wax in the middle of these bottom-bars; and from preliminary tests I believe it is going to be a success. The half-inch bottom-bars are a good thing.

I believe in feeding the bees of a newly hived swarm until they get the combs drawn out, and then they will do wonders if a good flow follows from the fields soon.

Jonesboro, Ind.

C. A. NEAL.

Is the Breeding of a Yellow-to-tip Bee an Impossibility?

I wish to take issue with the editor on page 393, July 1. If by breeding and selection we have obtained a bee that shows five bands yellow from the original stock of three bands, is it asking too much to expect to eliminate the last dark band?

Again, the editor says: "Yellow-to-tip bees or five-banded bees according to my light, is only the six-banded yellow bee that will be yellow to the tip." Does "to the tip" mean all but the last segment, or does it mean literally yellow to the extreme end of the bee?

Such a bee is yet to be produced, according to my knowledge; yet I deem it no impossibility.

Swarthmore, Pa.

P. G. SNYDER.

[As you say, a yellow-to-tip bee is yet to be produced. We have never seen any workers of that sort. We believe that they can be produced; but so long as it seems to be very difficult to raise queens that will produce all or 75 per cent five-banded bees, the prospect for producing six-banded or yellow-to-tip bees is not very reassuring. By "yellow-to-tip" we mean yellow all over the abdomen.—Ed.]

Where Did the Eggs in the Queen-cells Come from?

The other day when working with my bees I noticed that one colony had no young bees nor queens, but I found eggs in five queen-cells. I can not understand where the eggs came from when there were no other eggs in the comb. I watched closely, and found that the eggs never hatched. There was no evidence of laying workers, no drone brood, nor any thing of the kind. I gave the bees of this colony some eggs from another colony, and they reared a fine queen.

Yeager, Ky.

JOHN A. DAMRON.

[This looks as though those eggs had been stolen by the bees from another colony in an effort to rear a queen. There have been many instances of this kind, even in our own apiaries, and it seems hard to explain the presence of the eggs in any other way.—Ed.]

How Long Does it Take to Find and Clip 100 Queens?

How long does it take an apiarist to clip queens in an outyard of 100 colonies if it is done at the proper season? I am supposing that his time is fully occupied, and that he must work at it when he decides to go to the yard.

Galena, Kan., July 11.

J. P. BRUMFIELD.

[It depends considerably on the skill of the operator, and also upon what might be termed mere luck. The color of the bees has quite a bearing on the matter also. Small queens are hard to find, especially if they are dark. Even under quite favorable circumstances we doubt whether 100 queens could be found and clipped in much less than ten hours.—Ed.]

Good Year in Spite of Heavy Losses

I am getting more honey this year than I ever did before. I started with 20 stands in the spring, some of which were very weak, and I have had nine swarms. We had an immense locust bloom; then the berries and white clover came on, and the bees filled their supers faster than I could get them ready. The white clover is better, and there is more of it this year than for a long time. I have taken off 400 lbs. of honey, and will likely get 200 lbs. more, for all of which I get 16 cts. per lb.

Cheat Haven, Pa., July 18.

FRANK BAKER.

Our Homes

A. I. ROOT

When a man's ways please the Lord, he maketh even his enemies to be at peace with him.—PROV. 16:7.

If ye abide in me, and my words abide in you, ye shall ask what ye will, and it shall be done unto you.—JOHN 15:7.

And it shall come to pass, that before they call I will answer; and while they are yet speaking I will hear.—ISAIAH 65:24.

The year 1879 was an eventful one in my life. Obstacles came up in the way of my plans for developing bee culture; but the wonderful answers to prayer came thick and fast in enabling me in a striking way to surmount these obstacles. I will go over some of the events briefly.

In putting up the first brick building on the grounds we now occupy I became for a brief time somewhat financially embarrassed. The good friends here in Medina, and even my own relatives, were troubled about my getting the boys out of jail to work for me, and in expecting that God would answer my prayers for financial help, etc. All at once the way seemed blocked, as it were. None of my good friends were willing to advance me money any longer, and the man who furnished the brick for the first building declared he would have to have his money, and finally he said if it was not ready on a certain day he would make me trouble. Just then the little hymn from Moody and Sankey's collection, "Take it to the Lord in prayer," was very popular. It was my habit, in kneeling down with my wife at night, to tell the dear Lord of my difficulties, and ask him not only to direct me, but to furnish the means for doing his work. The man who furnished the brick said he would have to have his money on a certain day and at a certain hour. Almost immediately after this prayer a stranger, George O. Goodhue, of Quebec, Canada, visited our place, and volunteered, without my mentioning the matter, to furnish the money I needed. My friends laughed at me again for having faith that an utter stranger should send me money without security. On the day in question our mail came in about an hour before the time I had promised the money. I told the girl who was opening the mail that I was expecting a letter from Quebec. In a few minutes she sailed a letter over to my desk, saying, "There is your Quebec letter, Mr. Root." When opened I found it to contain a check reading, "Pay to A. I. Root \$500 in gold, and charge to the account of George O. Goodhue."

The brickman came in very soon after I had the check in my fingers, and was greatly surprised to find I had the money for

him. This whole event is fully recorded in the Home papers for 1879, with many similar ones. At that date I was manufacturing a fifty-cent smoker, and I made a reckless offer (as most people thought it) of giving one of these smokers to any beekeeper who would abandon the use of tobacco. The tobacco pledge was put in print in our "young" bee journal. First and last, more than *one thousand people* gave me the pledge and received a smoker; but at almost the same time that the man came from Quebec our good friend Bingham came down from Michigan, and informed me that my smoker infringed on his patent, just then taken out. After talking it over it seemed a question as to whether his patent would hold legally; but rather than to go into litigation (for that would disturb my spirituality more than any thing else) I gave way and made a promise not to make any more smokers. In fact, at that time I decided I would not go into *any thing* whatever unless I could honestly ask God to bless the undertaking. I told friend Bingham, after we had talked the matter all over very thoroughly, that I would stop making my cheap Simplicity smoker. I believe father Quinby had the credit of making the first bee-smoker to be blown by a bellows instead of using a tin tube blown by the mouth. Bingham's invention, however, was, without question, an improvement on the first rude smoker. When I told Mrs. Root my decision, she thought, as did some others of my friends, that my conclusion was hasty and even reckless. Let me quote my very words to her, from GLEANINGS for January, 1879: "If God has really directed me, in giving this up, he will certainly guide me in giving beekeepers something just as good if not better in place of it." I went to bed and slept soundly, although I did not know how in the world I should get smokers to sell at the low price of 50 cents, and a large part of them to be given away. Next morning, when I got down to my new office in the brick factory, a queer-shaped package from away off in California lay on my desk, and with it the following letter:

ALL ABOUT BEE-SMOKERS.

Having examined all the bee-smokers of the present day, as well as many of more ancient origin, and experimented not only with those of other makers, but also with several of my own make, I arrived at last to the following conclusions and objections:

All smokers made on the principle of blowing a blast of air through the chamber containing the fuel are defective for this reason: The fuel is made to burn up rapidly; and, worst of all, the smoke is hot; and who has not noticed how hot smoke irritates bees instead of quieting them?

The Novice smoker, on the score of simplicity, was far ahead of any I had seen; but its simplicity in one feature (having no valve) was an element of weakness; as in supplying itself with air from a point so near the fuel it inhaled smoke, which caused an accumulation of soot in the bellows; and during a long honey season of from 60 to 90 days, in large apiaries, it became disabled. The leather became black and hard, and it failed.

Having tried modifications of nearly all the principles claimed in other smokers with poor success, I set myself to work to remedy what I considered the defects of your smoker. 1. I put in my simplicity valve; 2. Instead of blowing my fuel when it was already burning fast enough, I concluded to blow my blast up through the fuel in a solid tube, ending far enough up in the spout (which I had added to the top of your fuel-case) to create a vacuum, and cause the smoke to rush in to fill this vacuum, and in so doing to mix itself with the blast of cool air, thus giving me a *cold smoker*. I then arranged a damper so as to regulate the draft to suit my fuel, and *Corey's cold smoker* was completed.

We have made a very thorough test of this little modification of your smoker, and found it satisfactory; and every beekeeper who has seen it and tried it says Bingham's is "nowhere." This vacuum principle is not any part of Bingham's *blow-hard, hot-blast, direct-draft* principle, and you are at liberty to use my improvements to your heart's content, without cost. I will mail you one as a sample, so that you can readily get the principle; and if it can be cheapened in any way, and not lose any of its merits, you can modify it. JOHN G. COREY.

Santa Paula, California, Jan. 12, 1879.
P. S.—If this gets you out of the smoker difficulty, I shall be fully rewarded. This offered relief comes further than the \$500 check did.

One day later.—In my hurry to send you a smoker I was compelled to use borrowed tools, use a piece of an old packing box for the boards, and put in a poor squeaking spring; and then after boring my outlet hole wrong, and various other mistakes and blunders, I finally got it ready to send off. Rough as it is, it will be a guide to you only as an application of the vacuum principle as applied to smokers.

I nailed it up without glue, so that you could easily pull it apart to see the valves.

Calf skin is best for the valves; $\frac{1}{2}$ -in. clout nails for fastening and clenching the spout on.

I use rags. Make a roll $1\frac{1}{2}$ in. in diameter, and about 8 or 10 in. long, and coil it around the pipe, so that the ends will not meet, thus, when it will burn only on one end and burn slowly.  JOHN G. COREY.

You will notice that friend Corey refers to the \$500 in gold that came from Quebec. The smoker that got me out of trouble came from still further away. Perhaps I might mention right here, that, a little later on, Mr. Norman Clark, of Sterling, Ill., sent me a sample of what was called Clark's cold-blast smoker,* which is the one our peo-

* Below I also give friend Clark's letter that came with the smoker.

I received my Jan. GLEANINGS promptly on time, and at once set myself down to read. Somehow I get to "Our Homes" very soon, and before one quarter of the book is read. When I read your talk with Bingham, and your decision about the smoker, I thought there might be some other plan of one that would answer as well; very soon a plan came to me, and I worked it out in its details.

Now, I have your Feb. number of GLEANINGS, and, lo and behold! you have the same principle embodied in one from a friend in California; but I have decided to send you the one I have made, and perhaps there may be some features about it that you may like even better than Corey's.

It works beautifully; the draft of air across the top of the fuel causes it to burn clear and slowly, and leaves very little cressote. I find that rags burn, but perhaps $\frac{1}{4}$ as fast as where the air is forced up through the bottom. Its convenience as a "breach loader" is an item in its favor, also that

ple at the present time now furnish at the low price of 55 cents. The first year after this cold-blast smoker was put on the market 20,000 of them were sold to the beekeepers of our land. I wonder if it has occurred to any of you that the cold-blast smoker was on the way from California before that little prayer, "Lord, help," was uttered in regard to the smoker question. Many people have said to me, "Why, Mr. Root, you are short-sighted, for the smoker was on the way, and it would have reached you just the same if you had not prayed at all." And right here just now comes in so beautifully that promise in the last text I have chosen—"Before they will call I will answer; and while they yet speak I will hear." Does it trouble you, my good friends, to grasp the great truth that the great Father above, who is the "alpha and omega," can put in motion the machinery necessary to answer our prayers (offered by his children), even before the prayer has been made?

The two incidents I have mentioned are only a few of the many that occurred in the year 1879. What has called the matter up just now is that our friend J. G. Corey is still living, and his picture will be found on another page of this issue.

Let me remark right here, that, away back in the early days, when Italian bees, or bees of any kind for that matter, were first sent to California, friend Corey was employed by the government to carry the mail where there were no railroads, and hardly any roads of any kind (for that matter) in those localities. He got a small colony at a big price, and made a very light hive for it, for the colony was really only a nucleus, and carried it on his shoulders *more than a hundred miles over the mountains*. Part of the trip could be made only on snowshoes. He got them through alive, and from that single colony alone he started an apiary. He built them up successfully; divided, and for quite a time he sold all he could spare, for *forty or fifty* dollars per colony; and that was the start of the great beekeeping industry in that region. Mr. Harbison, who took a carload of bees to California about that time, sold a great

it retains its position while in use. The Simplicity always seemed to me a little awkward, on account of being obliged to turn it bottom up so often, while in use.

Now, if you can use this to advantage, or modify it to suit you any better, you are welcome to it.

As a counterbalance to friend Sedgwick, I will say that the best part of GLEANINGS, to me, is "Our Homes." Four years ago I would have written as he does, but I see things differently now, and am happy in being able to place myself by your side, as a Christian. May God speed you in your good work, and bless "Our Homes." Your friend,

Sterling, Ill., Feb. 4, 1879. NORMAN CLARK.

part of them for \$100 per colony, and a few were sold at over \$200 each.

It was my pleasure, in 1903, to have a grand visit with both Mr. Harbison and our old friend J. G. Corey. You can imagine friend Corey's delight in not only astonishing the world with the *quantity* of honey he secured, but also with the *quality* of the California water-white sage honey.

In closing up this Home paper I wish to make a brief extract from an article in GLEANINGS, years back in 1879, headed "Troubles." It illustrates the difficulties we then had with the express company.

In May a customer from Texas ordered three \$3.00 queens. To avoid delays and save expense we tried to prepay the charges; but the express company could not tell what it would be over the southern lines, so they would not receive the money in advance. Time passed, and the queens were not received. A tracer was sent, and, after long delays, they were found held at some point in Texas. They were held until the back charges should be paid, yet neither myself nor my customer was notified where they were nor what the trouble was. The cages were made in such a way that the officials could easily see that they were bees, and perishable, and yet they put them up on a shelf, and let them die; and, nearly two months after, we were asked for the back charges, and whether we wanted the dead bees forwarded to destination. I sent back word that they should throw them out of the window, stifling my temper as best I could. They very kindly consented to do this, but sent back for \$1.75 charges for carrying them so far and keeping them until they starved. I felt very much, then, as if it would be inexpressibly delicious and soothing to be permitted the luxury of tearing that Texas man's shanty all down, and giving him such a shaking that he would never think of starving any more innocent bees as long as he remained in the express business. But I put away such thoughts, paid the \$1.75, and prayed God for patience, and that he would help us to soften even the hearts of the express companies. What do you suppose happened? Nothing different from what has happened a great many times in my business troubles and trials. A gentleman came in, a few mornings after, introducing himself as the superintendent of our express line. He said he had noticed the amount of business we had given them, and asked if he could do any thing to aid us. In a twinkling our printer had some neat little labels directing any express agent in the United States to forward the package it was on, without delay, under any circumstances whatever, signed with the superintendent's name. He also made arrangements to carry queens, smokers, etc., over any or all northern lines for one single charge of 25 cts., besides fixing many other things greatly for the comfort and convenience of myself and you.

I want to quote another sentence from that article, further on:

I felt again, that, when men held important positions, and were too proud and lofty to give us notice, God never was, and he would *always* answer.

No wonder such a faith and such a practice built up business. My prayers were not for self, as you may notice—at least not altogether for self, but for the friends scattered all over the world who were anxious to engage in the new industry of bee-keeping.

While on this subject it startles me to note that, during all of these years, the express companies have been allowed to do business, and still do it at least occasionally, in the way the above transaction indicates.

Below is a letter received this present year, as you will notice, from our good friend Corey:

THE COLD-BLAST SMOKER.

Necessity is said to be the mother of invention, which is true in this case, as something had to be done. In the early history of beekeeping in Southern California we were poorly provided with implements, and used our wits to make such as we were in need of, as the problems presented themselves. First of all, smokers were the old saucepan filled with many different kinds of fuel. This was used by nearly all the early beemen, utilizing the wind to waft the smoke where desired. Then came the two-inch tin tube, about a foot long, rags or old gunny sacks being used for fuel, and the breath of the beeman used to carry the smoke where desired. The results of this smoker were imperfect in only one case, where it never failed. Headache always followed blowing.

Then came the announcement of the invention of the Bingham smoker, which was patented in 1878, or thereabouts; but the dealers on this coast never sold goods "for their health," so the price was too high for us. Mr. A. I. Root, then publishing GLEANINGS, brought out a cheap smoker called "Simplicity," that answered our purpose, and it was going into general use. Then suddenly a cloud (no larger than a man's hand) came over the horizon, and threw our cheap smoker into a dense shade. Mr. Bingham notified Mr. Root that his Simplicity smoker infringed on his patent. That made a mess of our favorite smoker, and stopped its manufacture. I looked over the situation, and decided to run the cool-air tube up into the nozzle and create a vacuum, which would cause the smoke from the fuel-box to rush up and be blown out as desired; and that the cool air from the bellows, by not being passed through the fire-box, would furnish a cooler smoke than the Bingham smoker. I sent one of my cold-blast smokers to Mr. Root, and received substantial thanks from him. Now after over thirty years have come and gone, many different patterns of smokers have been invented and manufactured, all of them having advocates. All of them are fairly good, and moderate in price.

Our modes of handling bees, now that we all use a quilt out here, thus avoiding the snap in removing a sealed cover, and by breeding bees of a better disposition, enable us to use very much less smoke than in early days.

Many changes have taken place since then. Four years ago Mrs. Corey died, leaving me to finish up the battle of life alone. My health is fairly good; but my great age admonishes me to be ready at any time. I am 84.

Santa Barbara, Cal., Jan. 3. J. G. COREY.

The above letter reminds me that, in one of friend Corey's letters, he said, after seeing how successfully his smoker worked, he had designed to get it patented; but he finally told his good wife he would rather send it to A. I. Root, and have him improve it, and *give* it to the world at a moderate price, than to go to the fuss and bother of getting out a patent, even if it *should* prove to be of considerable value.

BE NOT WEARY IN WELL DOING.

Mr. A. I. Root:—In reading one of your articles in GLEANINGS for March 15, 1911, it led me to write you to know what you would do with a Bible class in Ohio of 52 ladies in a Congregational Church who had one of the best teachers a class ever had, and who was very anxious to have the class do something to help in God's work, such as rescuing the fallen or helping the Salvation Army in their work, or do something to down the white-slave traffic. They seemed to be so unheeding he became discouraged and resigned from the class. What can be done to stir up such women? I am a member of the class, and would like your advice. I ask God to help, and show me what to do. O. C. M.

My good friend, we can rejoice and thank God for two things that you make known in the above letter. The first is that there is a class of 52 ladies (young ladies, I take it) in the Congregational Sunday-school in your place. Secondly, we can rejoice and thank God that there is at least *one* praying woman in that class, one who is really "hungering and thirsting after righteousness;" and you know what the reward is. Keep on praying, and use every opportunity to plead for Christ Jesus, and show this, that I am dictating, to your good but discouraged teacher. Tell him that I say he should by all means and under all circumstances hold his place at the head of that class, and cease not to work and pray, for the promise at the head of our text is plain and sure. Sooner or later he will have his reward. You do not tell me how many of those 52 are professing Christians; but the fact that they continue to attend, at least in moderate numbers, is sufficient evidence that they are not so far away as you and he may think. Many and many a time during my past Christian life of 40 years or more have I become discouraged and almost ready to give up, when, lo and behold! in some unexpected way my prayers would be answered. Keep on hungering and thirsting after righteousness, you two, and you *shall* "be filled."

FLORIDA LAND SWINDLERS, ETC.; SOME OF
THE DRAWBACKS IN GOING DOWN
TO FLORIDA.

Dear friend Root:—I have been reading GLEANINGS for July 1 while it is raining this afternoon. I am glad to see you standing by your guns in the Florida swindling, for that is what a lot of it is. Next April will be 30 years since I struck Florida sand. I have not got rich, but I am content to end my days here. I have no desire to leave it. I have been from Pensacola to Key West, up and down, and across on foot, by boat, by wagon, by train. It is a big State, some of it as good as the sun shines on, and a lot of it absolutely worthless. The sad thing is to see men well up in years sell their homes and come down here under strange conditions, and blow in every dollar they have on propositions that those of us who know the country could not be induced to put a dollar into. A lot of them are paying for their experience right now; and if they alone suffered it would not be so bad; but women and children have to put up with conditions that are furious. There have been four or five years of exceptionally light rainfall, and it has given these schemers the opportunity of their lives, and they are using it. But I am inclined to think this season is going to put a damper if not a cold bath to a lot of it—over ten inches of rainfall in May, over 16 in June, and I think it has rained every day in July so far, with a prospect of this being kept up till mid September. This will likely give the muck-boomers some questions to answer that will be somewhat difficult. But as long as men are ready to listen to the fairy tales of men who are seeking for their cash, I do not know what you and I can do but refuse to be a party to it. To a man who wants a pleasant climate, and work out of doors, that will make a living or a little more, I know of no place I would rather risk than the right location in Florida; and there are plenty of them, but they are not in the hands of land-boomers. The successes are given,

not the failures. I have followed what you have written, with interest; and I think you have been fair. There are great opportunities in Florida, and there are great opportunities to blow your money in and never be able to find the hole it went into. The tenderfoot wants to go slow. About two years' experience right out in the field and he will begin to know something of Florida sand—its worth and its worthlessness.

Bowling Green, Fla., July 18. IRVING KECK.

I wish to emphasize the point our good friend Keck makes, by saying the good localities are not in the hands of the land-boomers. These "land-boomers," as he calls them, usually hunt up a tract that can be bought for a little money, or a little money compared to its real value. Then they start out with their spread-eagle advertising, and sell off lots or five and ten acre tracts until they get their money back several times over; and then they leave their deluded victim to sell out (if he can) and go back home. Let me give you a little history of a beekeeper here in Ohio who got so wrought up over the talk about Florida that he sold his home, farm, bees, and every thing, and moved down to Bradentown, expecting to make it his permanent home. His first setback (and this, perhaps, had considerable to do with getting him discouraged), was with the railroad company. He went to the agent near his home, and made a contract for a carload of household goods, etc., to be delivered in Bradentown. As he has a little automobile he asked if that could be put in the same car. The agent assured him that it could; but measurement showed that he would have to have a car with a wider door to get the machine in. This agent informed the railroad company, and they sent to Pittsburg and got a car with a wider door. The goods were all loaded in the car. He paid the price, and got a receipt in full for the shipment to Bradentown. Imagine his surprise and disappointment to find that, before the car could be opened, and before he could get his goods, he would have to pay an additional charge of something like \$200! This was the "penalty" affixed somewhere in Jacksonville for putting an automobile in the same car with household goods. Now, the automobile could have been shipped alone for about \$50.00. In fact, I have had two such shipments—one from Medina, O., and the other from Chicago, for only about \$50.00 in each case. The other \$150 or more was a *penalty* imposed on an innocent party—one who paid all the agent asked, and got his receipt in full. He paid some more money to a couple of attorneys for letting him know (?) that he could not well help himself. I took the matter in hand, however, and (with the aid of the *Rural New-Yorker*) I am not yet convinced that there is no redress.

I have thought best to mention the above because several parties coming from the North have been assessed additional charges—not quite so large, however—in several cases, even after they had the receipt in full, paid to destination.

Let us now go back to friend Klein, who came to Florida, I think, some time in November, on account of his health. He improved rapidly, and gained 15 lbs. in flesh, and was highly delighted with the change; but along in February or March the Florida grip or something else got hold

of him, and he became so sick and discouraged that I have just learned he has moved back to Ohio with all his family and possessions. I have not learned, however, whether he shipped his little automobile back or left it there.

Now, had this good brother taken friend Keek's advice, and spent a winter in Florida before going down there with his family and all his possessions, think of what he would have probably saved in money alone, and perhaps unpleasant experiences as well.

Poultry Department

EDUCATING THE LEGHORNS NOT TO FLY; SOMETHING ABOUT INEXPENSIVE FENCES.

Most of us have discovered, sooner or later, that chickens can be educated, like other animals, in the matter of getting over fences or through them; but I suppose only a few of us have ever considered the matter of educating chickens *not* to fly. I have discovered this in our Florida home—that, when they get a fashion of flying over the fences, it is a hard matter to stop them. Clipping one or both wings promptly with the first hen that starts the habit will often wind it up; and after our flock has been away from the yard during the summer they seem to forget about flying over; and although our fences in Florida are only four feet high, last winter we had almost no trouble at all by the hens getting out. Just before we came away a few had learned the trick. Now, here is something from the periodical called *Poultry* that is new to me:

Last spring we built our breeding-pens on a plan new to us. We made them long, and but six feet wide, as the breeding-pens were made up of small numbers, from six to fifteen birds in a pen. The sides of these pens were made of three-foot poultry-netting, and they were covered over the top with six-foot netting. This gave plenty of head room for the fowls, and these enclosed pens were cheaper than those with high fences would have been. We have enough of these pens to furnish room for all the hens we kept over, about 85. During the breeding season they were kept in these pens almost continuously, and they soon learned that they could not fly out of them because of the netting cover. Not being given to reasoning, these hens have come to believe that a fence is insurmountable, no matter how low it is, and do not try to fly over the 26-inch fence. I am led to this conclusion by the fact that two or three times when a hen has wandered into the garden through an open gate she would allow herself to be caught before she would try to fly over the low fence.

We have concluded to keep these hens in this notion of staying behind a fence. Every few days we simply leave them in the pens all day, and we believe we can keep them from learning that a low fence can be got over. If this continues to work we have learned to save time and trouble, for we can build the covered runs at small expense, and orchard fences cost money, and a lot of it, in this country. Any one who will go to the trouble of building low covered runs such as we have used this year can

soon solve the problem of keeping fowls in subjection; and we consider this one of the most money-saving things we ever learned about the habits of fowls.

This covered poultry-yard, as described above, is a splendid arrangement for a hen and chickens where hawks are apt to be troublesome; and a three-inch-mesh netting, which is comparatively cheap, will answer overhead as well as any. Another point comes in right here. A two or three foot fence that would never answer to keep chickens *in* a yard will do excellent service in keeping them *out* of the garden. I have seen a two-foot fence keep Leghorns off the garden all summer—that is, unless some one of them happened to discover how easy it was to get over. Now, this point we have been speaking of applies to turkeys as well as chickens; and the same letter I have quoted from gives us the following:

We might add that our bronze turkeys have never been inside the orchard, although they were hatched and raised around the poultry-yard. In fact, these same turkeys, hatched in the spring of last year, have never been confined in any way—have unlimited territory over which to roam, and yet we have never caught one of them ten rods from the place where they were hatched.

You see the turkeys, had they been confined by a 26-inch fence, would have gotten out without any trouble; but when it was getting *into* the orchard, instead of getting *out* of it, it was a different thing.

Now, here is something more from the same periodical:

BEEF SCRAP FOR LAYING HENS; HOW MUCH AND HOW LITTLE IS NEEDED.

This season we concluded we would try to discover just how little beef scrap we could use and still get the maximum number of eggs. We soon found that we could reduce the quantity of scraps fed to the place where egg-production would fall off in a very noticeable way. Between 5 and 8 per cent beef scraps in the regular feed of hens seems to be about right. If cut below 5 per cent the number of eggs gathered becomes less almost at once. Feeding 10 per cent beef scrap seems to promote growth in young chicks, but hens do not seem to lay better than they do when a little less is fed.

Please consider that if your fowls, or, say, hens and chickens, have a run where

they can scratch and get more or less insects, the animal food may not be needed; but where they are kept in yards, in order to get the best results they must have both green food and meat in some form.

THE CONVERGENT POULTRY-YARD AS DESCRIBED IN OUR JULY 1ST ISSUE.

At the present writing, Aug. 1, I am a little disappointed to find so little notice taken of this new departure, for I am sure it is destined evidently to cut an important figure in farming and in poultry-raising in general. One of our agricultural papers mentions a dairy barn to be made on this principle. The silo stands in the center of the barn, which is circular; the cows with their heads toward the center. The feed is taken from the silo right across the alley to the cows' manger. The manure is gathered by driving around the outside of the barn. Although I am but little conversant with the dairy business, it seems to me this would be a wonderful saving of expense and time. But to get back to the matter of poultry, just think of the convenience of having eight, sixteen, or possibly more yards, for that matter, all running up to a common center. If a broody hen is found, just let her loose in a vacant yard. You can give her a setting of eggs, or break her of sitting, without any delay or running back and forth; or suppose you have a hen with a lot of chicks, no matter whether it is a common brood or sixty or seventy, as I manage, just put her in a vacant yard, where her wants and those of the chickens are all supplied, and they are also perfectly secure from all sorts of poultry enemies. At little additional expense you can also keep off hawks and owls as well as rats and wild animals. When you wish to separate the surplus cockerels, every thing is all fixed for that without any trouble. Any number of choice breeding-pens can be started in a twinkling; and every fowl in your possession has free range, and yet can be made perfectly secure at night without any chasing about.

In my Florida home last winter I had seven yards, besides the ducks. The yard for my cockerels was away off in one corner of my square five-acre lot. The ducks were in another corner, and my best pen of Leghorns in still another corner. This last pen was down near the creek by the boys' swimming-hole, and several times a dog got in among my chickens. They were so far away from the house that they were more meddled with than in the other yard. Now, with the convergent yards all the fowls on the ranch can be close by where

you sleep, so that it is an easy matter to note a disturbance in the night. At the same time, they can each and all radiate during the day all over the five-acre poultry-farm. A similar arrangement can be made for hens and chickens, say on a small scale. Most of you know how much work it is to take care of, say, half a dozen hens with chicks of different ages. Suppose each hen with her brood could come right up to some central point where you have chick feed, grit, oyster-shells, water, and every thing they need. All you have to do is to go into this central inclosure, close by your home if you choose, and every hen with her brood would rush up for the rations—no fighting nor quarreling. To save labor I used to have my chick feed kept in a covered can. The can had to be lugged back and forth from one yard to another, or else I was obliged to have a similar covered can near each hen with her brood. Of course the same arrangement works equally well with a fireless brooder or lamp brooder. You can have a dozen different brooders if you like, and one roof may cover them all, with radiating yards, so that the chicks may have range as fast and as far as they need it. I notice the poultry journals are recommending that each pen of fowls should have two yards, so you can grow green stuff in one yard while the fowls occupy the other. The radiating yards would be the nicest thing in the world for this purpose. Some one may suggest that this all sounds well enough on paper. Well, Providence permitting, in a very few days I expect to have the fun of arranging it on my five acres in Florida; and I am going to try to have something I shall not be ashamed to show visitors when they come around. May be it would pay you during the winter time to take a trip down to that land you have all heard me talk so much about.

MUSTARD TO START HENS LAYING AND TO KEEP THEM LAYING.

Since saying what I did about mustard, from the book entitled "The Corning Egg-farm," and what I copied also from E. L. Keyser, there have been constant inquiries made in regard to how much mustard, how to feed it, and how often to feed it. I presume this will have to be settled largely by trial. I wish our experiment stations would lend a hand. All I know about it is this: I purchased a box of ground mustard at the grocery, and put a heaping teaspoonful into half a pailful of mash made of bran shorts, middlings, Indian meal, etc., stirring it thoroughly so as to have it distributed all through the dry bran. Then this was wet

up with water and given to about 75 hens every day. We also fed to little chicks the same mixture. During the time it was fed we had the most eggs we ever had from a like number of fowls. At the same time we gave them quite a little green mustard—the Florida kind that makes leaves some two feet long. The hens eat this very greedily, and I do not know but the green mustard might take the place of the more expensive ground kind. The Cornings use mustard bran bought at the mustard-factories, costing about a fourth as much as the ground mustard for table use. I presume it would be best for each one to make experiments according to circumstances. We have abundant evidence from different sources showing that the use of mustard, instead of being a detriment to fertility, acts quite the contrary. In fact, some stations have reported that they had a higher degree of fertility with hens fed quite liberally with mustard. We should be glad to hear from poultrymen, besides the Cornings, who have tested the matter on a considerable scale.

A HOPPER FOR WET MASH.

Like yourself I have dropped the bees a little, and changed the hobby to poultry. I keep White Leghorns, White and Buff Orpingtons, and Indian Runner and Buff Orpington ducks. I hatch with a Cypher incubator, and rear in Philo brooders and hovers. Philo hovers are good, but the brooders want to be in an open shed for the assistant's comfort. I know from experience with six this season. I have been puzzled over an efficient hopper for feeding wet mash. I got it at last. Make a tray, say 18x12x2; cut one end out of a 60-lb. honey-tin or kerosene-tin, and then cut back 1½ inches; put in your "wet" mash which should not be wet, but crumbly—the right condition for fowls; place the tray on it and turn it upside down; and if your fowls are like mine they will empty it clean without waste.

This hopper question for a "wet" mash cost me some experimenting and brain gymnastics, and the above simple arrangement beats all I've tried.

WM. CHAS. BROWN.

Mosguel, Otago, New Zealand.

Permit me to explain that the tin can is cut off on opposite sides in such a way that, when inverted in the tray, there is a 1½-inch opening to permit the wet mash to get out to the chickens or to permit them to reach in and get it. I think the idea is a good one, especially for ducks, which are very much inclined to get their feet into the mash, and to make things "mussy" generally.

Health Notes

APPLES ARE RIPE.

I suppose that, this first day of August, most of you are rejoicing, like myself, in plenty of nice ripe apples; and even where you have not the pleasure of plucking them from your own trees when they are fully ripe, you are probably able to purchase them at the groceries or at the fruit-stands at a reasonable price. At least they *ought* to be reasonable, as apples are going to be plentiful in many localities.

The first to ripen here in Ohio are the old-fashioned Early Harvest, and the comparatively new Yellow Transparent—at least I have not been able to discover that there is any earlier apple known than the two I have just mentioned; and they are certainly a wonderful and beneficent gift from the great Father above to his hungry children. I do not know how it may be with the rest of you; but for myself there is no other fruit in the whole wide world that will take the place of luscious ripe mellow apples. I do not know which I like better—the Early Harvest or the Transparent. Sometimes I think one is ahead, and at other times the other. When the Transparent is so ripe that it can be peeled like a plum or a peach, it is then just right for my taste and for my digestion. When the old apples were all gone, about July 1, I began testing other sorts of fruit to see

if they would take the place of the apples; but I found nothing to hit the spot.

Frequently in very warm weather I have a little tendency to what used to be called "summer complaint;" and for several years I had a notion at such times that I would have to abstain from fruit. Three or four years ago, however, I discovered that nice mellow apples, eaten freely in place of my usual supper, about 5 o'clock, were really the best remedy. Please do not imagine, however, that I mean that sweet or very sweet apples can be taken in this way. They are pretty sure to make trouble. But tart apples, like the two kinds I have mentioned, seem to neutralize and quiet the disturbance. The acid in the apples (malic acid, I believe) seems to me to be nature's remedy for a bad taste in my mouth and for a disturbance in my digestive apparatus. In ordinary health I eat four or five fair-sized apples, sleep soundly afterward, and awake in the morning (especially if I sleep outdoors, or somewhere equivalent to outdoors) with my mouth tasting sweet and clean—no bad breath, no unpleasant bitterness.

Now, of course I can not be sure that the use of apples will answer in a like manner with everybody else; but I enjoy my fruit so much, and it is so conducive to excellent health, that I feel free to urge

you to try it. In place of your regular supper or third meal, use simply apples and nothing else; and after nature catches on to the fragrant program, see if you do not experience a like benefit with myself.

After the two early apples I have mentioned, the Red Astrakhan comes along—one of the most enticing-looking apples with its beautiful streaks and variations of red, then its delightful acid juiciness. A little after the Red Astrakhan comes the Maiden's Blush, so justly celebrated over all the world; then the Gravenstein, that stands almost if not quite at the very top of the list in quality. After this the rambos and pippins, too numerous to mention.

Just now our good friend E. C. Green, formerly with the Ohio Experiment Station, sends me a little basket of Red Junes. The shape is conical, somewhat like the Yellow Transparent; but the red is its distinguishing characteristic. When fully ripe, some specimens are of such a deep dark red that they are almost black. I believe there is an apple called the Black Ben Davis; but I have never seen one so red as this deep dark-red apple, the Red June. The Red June in quality is hardly as acid as the Yellow Transparent; but it is a beautiful apple notwithstanding.

Now, almost everybody can have at least a few apple trees. If you have room for only one, have that; and when you get it, give it good soil and cultivation. Learn to prune it judiciously, and enjoy the fun of seeing the apples grow from bud to blossom and then to ripe fruit ready to be gathered by your own hand. Unless you have had experience you do not know what a difference there is in fruit grown under cultivation and otherwise. Some years ago I had a queer neighbor whose great hobby was stable manure; and in the midst of his stable-manure garden was an apple tree. When the apples were just ripe he handed me a good big yellow mellow one. I tasted it with a happy surprise, supposing it was a new variety; but he informed me, with a smile, that it was only the well-known Early Harvest under the stimulus of "high-pressure gardening." And this reminds me that you want to study up on spraying so as to avoid getting wormy apples. A great part of the world does not yet know or dream of the possibilities in the line of improved apple culture. I wonder if it will be wrong to paraphrase as follows the old saying usually credited to good old Izaak Walton: "Doubtless God *could* have made a better fruit than the apple; but doubtless he *never did*."

DR. WILEY TALKS TO US ABOUT HABIT-FORMING DRUGS FOR CHILDREN.

We clip the following from the *Union Signal*. It is part of an address given by Dr. Wiley at the 50th anniversary of the National Educational Association at Chicago, July 6 to 12.

Through the teachers he gave to the fathers and mothers some wise advice: "Don't let the children use stimulants—distilled alcohol, tobacco, tea, or coffee. Those are wise parents who forbid these things; and yet right under the nose of the parents and of the city fathers in every drugstore in this city the children are permitted to buy at the soda-fountains 'dope' drinks which contain the very alkaloids and stimulants which the parents keep out of their children's mouths. I want the teachers of this country to help me engage in this crusade to put a stop to the sale of medicated drinks at the soda-fountains. You do not now find much cocaine in the drinks, but there are hundreds of so-called soft drinks which contain caffeine in large quantities. Coca Cola is a type of this 'dope' drink sold all over the country to the injury of every man, woman, or child who takes it.

"Another danger to which our children are exposed," declared the doctor, "is the everlasting habit of drugging themselves. The continued use of these medicines and drinks will in time produce a taste and craving for drugs. The school is the proper place in which to create an anti-drug sentiment, so that the next generation may not be ruined by the habit."

Directing his remarks for a minute to any editors who might be in the audience, he said: "Editors, do you realize your responsibility for admitting into your columns every kind of so-called remedies for any kind of disease? By so doing you are threatening the very bulwarks of the country."

As an illustration of the value he placed upon the ordinary cold remedy, he told the following incident: "My barber came to me last winter, telling me that his children all had colds, and he had procured from the drugstore some remedy guaranteed to cure these troubles. 'But,' he complained, 'I find it contains ten per cent of alcohol, and I don't want to teach my children to become drunkards. What would you do?' I said to him, 'I will give you a prescription if you will take it. Take that bottle to-night, into the room where those children sleep, and open wide every window, then throw out of a window the bottle of stuff, and leave the children to sleep in the room, and I'll warrant your children will get well.' A few days later I met him, and asked the result of his use of my prescription. With a glum look he replied, 'Taint no use to tell a woman nothin.'"

In closing his address, the doctor said:

"I believe it is the schoolroom, not the national conventions of politicians, that is the hope and safety of this country, and I for one will never despair of the republic if all the teachers will preach to the people sanitation, hygiene, fresh air, and abstinence from 'dopes' of all kinds."

I have for a long time felt that we were not only wasting money but harming our children, and, for that matter, grown-up people, by patronizing the soft-drink stands at our drugstores. People who talk about the "high cost of living" seem to think it is a small matter to spend a few nickels every day for ice-cream and ice-cold drinks. I feel sure this habit has much to do with the digestive troubles that afflict our people of the present day. And the saddest part of it is that the victims of these troubles imagine they are going to get relief by going back to the same drugstores and buying patent medicines.

Just a word about sleeping in a tight

room with doors and windows shut, even in summer. Mrs. Root called my attention to the fact that a great many children or young people—young girls who need pure air, perhaps, more than they need any thing else—persist in shutting every door and

window of their sleeping-room. Talk and remonstrance do not seem to do any good. They seem to think it an invasion of their rights if the suggestion is made that, during sleep, one needs the best air, and all the air there is outdoors.

Temperance

A DRUNKEN ENGINEER, ON THE MORNING OF
JULY 4, CAUSED THE DEATH
OF 41 PERSONS.

The Cleveland Press says:

SAYS ENGINEER WAS SERVED GIN; BARTENDER DECLARES SCHROEDER DRANK BEFORE WRECK.

Engineer Schroeder, who was in the cab of the express train that smashed into the Buffalo limited on the Lackawanna railroad near here early Fourth of July morning, causing the death of 41 persons, will take the stand in his own defense next Monday afternoon.

The coroner's inquest was adjourned Thursday until that time, on the assurance that Schroeder will then be sufficiently recovered from his attack of nervous prostration to tell his side of the case.

One witness has flatly sworn that Schroeder was drunk less than four hours before he took his train out. Three other witnesses, called late Wednesday, declared this false.

Other witnesses swore that they saw Schroeder assisting an intoxicated neighbor home four hours before he left on his run. Two saloonkeepers testified that Schroeder drank only water.

Charles Sharp, a bartender, testified he sold gin to Schroeder the night before the wreck. Schroeder had at least two drinks of gin, Sharp testified.

That Schroeder was called twice to go out on the run was made a part of the records.

Of course an effort was made or is being made to prove that the man was not drunk. You may be sure the brewers and liquor men will be on hand and ward off this terrible blow at this business if possible. The above clipping intimates as much. Now, right away after this comes a decision by the Pennsylvania road to drop liquor, as will be seen by reference to the item below.

THE GREAT RAILWAYS AND THE WAY THEY
ARE COMING TO OUR RESCUE.

Here is a clipping from the *National Stockman* that not only pleases me but suggests something I had not thought of. Read it:

LIQUOR ON TRAINS.

The Pennsylvania Railroad announces that the sale of intoxicants will be discontinued on all its trains east of Pittsburgh, and that the same rule will be extended to all roads in the great Pennsylvania System. We believe the public should express its approval of this policy, and hereby record ours. The railroad is bound to be the recipient of a large assortment of knocks and kicks from those who want intoxicants served on trains, hence it should have the moral support of those who believe its policy to be right. Railroads forbid their employees to use intoxicating liquors, and are inconsistent to the last degree when they sell them and compel some employees to handle them.

I confess it had not occurred to me, the awful inconsistency of demanding that employees should neither drink nor be found in a saloon, whether on duty or off, and at the same time sell liquors and ask employees to act as bar-tenders for the millionaires

who may happen to ride in their Pullman cars.

How long is it going to take the rest of the world, say manufacturers, for instance, to come out in the open, and declare war on the liquor traffic?

Later.—The following, from the *Plain Dealer*, corroborates what I have just been saying:

Employees of the Delaware, Lackawanna & Western Railroad must not drink, either on or off duty. Neither are they allowed to play poker during hours of idleness. All of this appears in the new order amending Rule G., of the transportation department of the line. A part of this amendment reads:

"The use of intoxicants while on or off duty, or the visiting of saloons or places where liquor is sold, incapacitates men for railroad service, and is absolutely prohibited. Any violation of this rule by employees will be sufficient cause for dismissal."

Investigation of the recent disastrous wreck at Corning, N. Y., led to the issuance of this order.

So it seems that prohibition *does* prohibit—at times.

We clip the following from the *Union Signal*, under the heading "Era of Prosperity in North Carolina."

EX-GOVERNOR GLENN, OF NORTH CAROLINA, TESTIFIES TO IMPROVED CONDITIONS
IN HIS STATE.

At the recent meeting in Louisville, Ky., of the General Assembly of the Presbyterian Church, Ex-governor Glenn told of the advance in his State since it abolished the liquor business:

"I come from a State where we have driven liquor out, and there is no grass growing in the streets of any of our cities and towns. Whereas North Carolina was noted—and shamefully so—only for her tar, pitch, and turpentine—now the State is entering upon an era of prosperity the like of which she has never known. She is gaining by leaps and bounds and this is attributed to state-wide prohibition. Crime has diminished fifty per cent, as is shown by the fact that forty prisons in the State are empty and idle. Formerly mothers were ashamed to allow their children to go to school because the fathers had taken the clothes from their backs that strong drink might be purchased. Since 1907, when the State went dry, the school attendance has doubled. There has been an increase of one-half in the attendance at the Baptist, Methodist, and Presbyterian churches, and a great wave of spirituality has swept over the State.

With the above report in view, and a number of similar ones from prohibition States, how *can* the people of any State continue to vote wet?

WET AND DRY IN OHIO.

Somebody has remarked that great reforms go by waves, and that every big wave for righteousness has a lull following, or perhaps a receding. When so many Ohio counties voted dry all at once, a good many

of us were discouraged at the backset the other way; but is it not possible that another wave for temperance is gaining force and volume? See the following, clipped from the *Cleveland Plain Dealer*:

BRYAN, O., July 23.—Williams Co. voted to-day under the Rose law, and by a majority of 1779 decided to remain dry.

How does that sound—1779? Praise the Lord for nearly 2000 majority on the "safe and sane" side. I feel a little sorry, however, that our friend the *Plain Dealer* did not have just one word of encouragement for the good people who worked so hard to bring this about.

While we are about it, here is something more that just came to my attention:

After October 1, absinthe, which is being sold in increasing quantities in the United States, will be barred from importation, and also from being transported from State to State. The Pure-food Board to-day decided that absinthe as a beverage is dangerous to health.

We rejoice to know from the above that absinthe is ruled out because of its being a dangerous habit-forming drug, and also because it can not be any longer transported from State to State. Now if Uncle Samuel would just say the same in regard to intoxicating liquors, what an achievement it would be!

By the way, the French government is now engaged in a conflict against absinthe, as its direful effects are getting to be so widespread as to affect materially the welfare of the nation. Its use was introduced into France from Algiers, where the French soldiers became greatly addicted to its use. Its use is now forbidden in the French army.

Later.—Switzerland has prohibited the drug.

BEER AND POLITICS.

See the following, from the *New York Tribune* for July 30:

LINER'S CARGO ALL BEER; GALLEON OF AMBER TREASURE COMES TO OUR RELIEF.

A great cargo of beer stole into this port last night under the cover of darkness in the hold of the North German Lloyd liner *Main* from Bremen. She had a few passengers, but they were outnumbered twenty-five to one by beer-kegs.

When the report came up from Quarantine that the *Main's* entire cargo consisted of 2583 barrels, Herr Knirim, the beer expert of Hanover Square, was called up on the telephone and told of it. He bubbled over with delight, so to speak. "I am not surprised," he said. "I thought something like that would happen. There has been a shortage of Pilsner and Munchner since the political conventions at Chicago and Baltimore, and the sangerfest recently held in Philadelphia has been a big item in diminishing the supply."

"The cargo in the *Main* is a big beer consignment. There are not many importers of beer in this country, and the biggest of them imports only 61,000 half-barrels a year."

When it comes to pass that a political convention results in a shortage of beer in our large cities such as Philadelphia, Chicago, and Baltimore, to the extent that

it exhausts our own national resources, what sort of president and governors can we expect from such great political conventions? We are much obliged to the *Tribune* for turning on the limelight, even should it prove true that their sympathies are with the brewers.

ELECTROCUTING THE MAN WHO SOLD THE DRINK, ETC.

Mr. A. I. Root:—In GLEANINGS for July 15, page 460, I notice you use the following language: "But if anybody is to be electrocuted, let it be the man who sold the drink." Now, my dear friend, I trust you will pardon me if I take issue with you on that point. Would you sell a man the right to engage in a certain line of business, take his money for the privilege, put it in your pocket, and then electrocute him for engaging in the business that you have just sold him the right to engage in? The man who sold the drink was doing a lawful business, and had paid his money for the right to do so. His business is made lawful by the party in power—a party that is sustained and kept alive by the vote of Christian men who knowingly sustain the liquor traffic by voting for a party that has legalized, upheld, defended, and protected the liquor traffic whenever in power ever since the party had an existence, and is doing it to-day.

It is easy to see why prohibition doesn't prohibit—because the law is put into the hands of old whisky-party officials who don't want it to prohibit. "Put new wine into new bottles, and both are preserved."

Morenci, Mich., July 17. W. S. G. MASON.

Amen to what you say, Bro. Mason. When I said what I did, I did not contemplate voting for a man who is afraid to "come out in the open" against the liquor business. Now it is up to Woodrow Wilson to come out thus and tell us whether or not he has anything to say in regard to the rum traffic.

WHO SHALL BE ELECTROCUTED? ETC.

Mr. Root:—In commenting on Thomas Dewees' letter, page 460, July 1, you say the letter has given you a new suggestion, saying, "Do not put to death any more men who commit murder under the influence of drink; but if anybody is to be electrocuted, let it be the man who sold the drink." I shall have to differ with you as to the one who should be electrocuted (if any should). I say, electrocute the man or men or political party who gave the man the privilege to sell the drink that makes men drunk and then commit murder without a license. I am not a saloonkeeper, by any means; but let us give them their just dues. A saloonkeeper, so far as the liquor traffic is concerned, is no worse than the man or men or political party that gives him the license to sell the drink. This thing of laying the blame on the saloonkeeper for all the drunkenness and murders, etc., is old. It would have done 25 years ago; but we have become too much enlightened now to lay the blame on them alone. Lay it where it belongs—on the voter. You say, under the heading "Prevention Better Than Cure," "Not one of the candidates for the presidency of the United States—that is, one with any prospects of election—dares open his mouth in regard to recommending prevention as being better than cure." Who really knows who has any chance of election? If all the church members who vote, and all the professed Christians, would vote for the candidate who dares open his mouth in regard to recommending prevention as being better than cure, we could put Mr. Eugene Chafin in the White House in 1913. He is the man who, if elected, would "make mention" of the liquor traffic in his message. I am like you in some respects. I am watching and praying, and also voting for a man and party that fears God but does not fear the liquor powers.

Rosedale, Ind., July 29.

NO. 17

Editorial

WE are pleased to announce that Mr. F. W. L. Sladen, F. E. S., of Ripple Court Apiary, near Dover, England, has been appointed as assistant in apiculture to the Dominion Entomologist, Dr. Gordon Hewitt, of the Department of Agriculture, Ottawa, Canada. Mr. Sladen has a high reputation as a beekeeper and also as a student of entomology, having studied the wild bees and other hymenoptera in various parts of the world. We congratulate both Dr. Hewitt and Mr. Sladen.

CLOVER STILL YIELDING; A BUMPER CLOVER CROP FOR NEXT YEAR.

ELSEWHERE we have spoken of the belated clover flows in the United States. The clovers are still in bloom, in some localities, and are yielding some honey when the weather turns off warm. In fact, there has not been a day in our locality since the last of June when clover did not yield some nectar, provided the bees could fly and the weather was not too cool. We have had less robbing than for many years back. The frequent rains have made every thing yield nectar. As usual, rains have been more or less universal over the northern half of the country; and it is apparent that, unless there is a very severe drouth in late fall, or a bad winter-killing later on, there will be an unusual crop of honey from white clover next year, for there is a heavy growth of clover almost everywhere in the North.

DEATH OF ANOTHER VETERAN BEEKEEPER, LAWYER, AND STATESMAN.

WE are sorry to have to announce the death of the Hon. R. L. Taylor, of Lapeer, Mich., on the 17th of August, at the age of 72 years. Mr. Taylor was one of the leading beekeepers of the country, and for many years director and legal adviser of the National Beekeepers' Association. He was an attorney and statesman of ability. He was not only an up-to-date beekeeper but a progressive fruit-grower—a man, in

fact, who took an ardent interest in all outdoor pursuits.

He had much to do with shaping the legislative policies of the National Beekeepers' Association, a warm friend and supporter of the late W. Z. Hutchinson, an admirer of Mr. James Heddon, and a user of his divisible-brood-chamber hive, of which he had at one time upward of 500. He was an occasional contributor to all the bee journals, writing particularly for the *Beekeepers' Review*.

At one time he conducted a valuable series of apicultural experiments for the State of Michigan, reporting the results in the *Review*. He will be missed in the councils of beekeepers, not only in Michigan, but throughout the United States, for he had come to be a man of national prominence in the beekeeping world.

ANOTHER INSTANCE OF HOW THE SPRAYING OF FRUIT TREES HAS DESTROYED THOUSANDS OF DOLLARS' WORTH OF BEES.

In this issue, in the department of Beekeeping Among the Rockies, by Wesley Foster, there is given some pretty convincing evidence to show that the spraying of fruit trees with arsenate of lead to destroy leaf rollers and the codling moth has resulted in the destruction of an immense amount of brood and bees. It is further stated that a Mr. Harvey, of Montrose, estimates his loss as over \$2000, the result of such spraying.

While Paris green is often used for the spraying of fruit-trees to kill the leaf rollers and codling moth, arsenate of lead is getting to be more generally used. Whether it is more destructive to bees than Paris green, we do not know; but apparently our leading fruit-growers regard it as a very superior substitute for Paris green. It may be admitted that in some cases bees are not killed by the use of these poisons, yet it seems to us that the proof is becoming more and more conclusive that fearful destruction is and has

in many cases been brought on the bee business when fruit-growers are so ignorant of their own interests as to spray while the trees are in bloom. This matter should come before our State and national associations of beekeepers, to the end that the needed legislation may be secured to protect beekeepers against their ignorant neighbors the fruit-growers. There should be little or no opposition, as our leading horticulturists admit that it is a positive damage to spray while trees are in bloom.

HONEY-CROP CONDITIONS.

THERE is not much to add to what we have already given on pages 509 to 512 in our last issue; but the spell of cold rainy weather that has prevailed over the United States during the last two weeks would have a tendency to cut down the yield where belated clover was still in bloom, for it should be understood that clover came into bearing this year much later than usual, and continued over a longer period. The effect of chilly weather of late will have a tendency to make the general clover crop in the East somewhat lighter than the earlier indications showed.

PRICES.

By consulting the Honey Column in this issue it will be seen that the market is a little unsettled with a tendency to maintain last year's prices. There should not be a slump in prices, because California and some other parts of the West will not have as large a crop as usual. The shortage in bees in the East will have a tendency to hold prices level. If there comes a general reduction by reason of a big crop of white-clover honey that is still in the hands of the beekeepers, it will be when this honey is unloaded and reaches the general market. The opinion seems to prevail that there is a large amount of clover honey still held back, and that prices are now as high as they will be this season; that those who have a crop ready to market would do well to sell at once.

LATER.—Late reports indicate that the clover and basswood crops in Illinois and Wisconsin are going to be light. The cool weather coming on just when the season should have been at its best, checked the flow of honey. As Illinois and Wisconsin are two of the principal States for the production of clover honey, it will reduce the general aggregate of clover.

Reports from other sections of the country in the East are very favorable. The State of Maine has had apparently a good crop. See the following:

From all reports, so far as I can tell, we have had in this State one of the best seasons for honey in many years. Nearly every one who comes here for supplies tells of the wonderful yields they have had. Not one, but many, have reported that they have taken off two and three complete supers, and the bees were at work in the third and fourth supers. This is extra good for this State, although it would indicate by reports that the yield had not been quite as good in the eastern part of the State as in the western.

Mechanic Falls, Me., Aug. 15. J. B. MASON.

Here is also a report from Mr. Crane, of Vermont, just as we go to press:

Bees have done fairly well here; but the drouth in July cut short the crop—an average crop, I think.

Middlebury, Vt., Aug. 21. J. E. CRANE.

THE LAST OF THE SPECIAL NUMBERS FOR 1912.

THIS special number on wintering completes the six special numbers that we advertised for the year 1912. We believe that most of our readers have appreciated the effort that we have made in placing before them practically a whole number of GLEANINGS containing the information that they needed most at the time. We are well aware that we can not please all of our readers all of the time. This special number, for instance, will have little interest for our subscribers in California and in the South; and the seasons are so different in many of the foreign countries that discussions on wintering would be more timely if they came in February or March; but it has been our aim, as we said before, to please the largest number possible.

There have been two who have objected to our special numbers. One of our friends, after reading the February 15th issue, wrote us that, if we were going to turn GLEANINGS into a poultry paper, he would quit then and there. He had not noticed the announcement of our special numbers, and did not know that we were having more to say about the combination of bees and poultry than usual in that number. Another thought that we were hardly giving full value for his money when we devoted so much space in the April 1st issue to automobiles. We have had hundreds of letters of appreciation, especially of our horticultural number, and also of the one on swarming and increase.

We should like to know whether there are other subjects on which it would be worth while to devote a whole number of GLEANINGS. If you have any ideas on the subject, let us have them on a postal card. Already several have suggested that we have a special number on beekeeping for women. It is probable that we shall

arrange for this some time next year; and in anticipation of it we should be very glad if our readers belonging to the gentler sex would send us their experiences. Why did you take up beekeeping? What are you making out of it? If you do all the work yourself, how do you manage about heavy lifting? Where do you sell your honey? We shall, of course, appreciate good pictures; and for all of those that we can use, and for such articles as we accept, we shall expect to pay probably a little more than our usual rates.

TENEMENT HIVES FOR OUTDOOR BREEDING.

In this issue will be found several articles describing various forms of tenement hives for wintering bees outdoors. Some thirty years ago this scheme of wintering groups of hives in one big winter case, with packing between the hives and the walls, was exploited a good deal more than it has been during late years; but during the last two years there seems to have been a simultaneous if not a spontaneous movement on the part of a number of beekeepers to go back to the old principle. Apparently there was no previous understanding between these various parties. Cellar wintering, under average conditions, does not accomplish all that is desired; and perhaps we may say the same is true of the ordinary outdoor wintering; but Mr. R. F. Holtermann, of Brantford, Ont., one of the number who have adopted the tenement principle, apparently did so, not because it wintered bees any better than the old way of wintering in the cellar, but because bees, when packed outdoors, do not require any further watching or manipulation till quite late in the spring, when they need to be equalized and other spring work of a like character attended to. It so happens that Mr. Holtermann had other work to do during the winter, and he was compelled to adopt some form of wintering that requires less constant watching of temperature and ventilators than the ordinary up-to-date cellar demands. It should be understood that Mr. Holtermann had one of the best bee-cellars, if not the very best, in the United States or in Canada. In fact, this cellar is shown in our A B C and X Y Z of Bee Culture as an ideal cellar. That Mr. Holtermann wintered his bees successfully in such a cellar is not to be doubted. He would have been using that cellar to-day, probably, had it been possible for him to be at home during the winter, when he could control conditions. Now, he can be away all winter, let the bees sleep for six or seven months, and

yet during all that time, with not a soul near them, he has the very comfortable feeling that his bees do not need attention, because they can take care of themselves.

For very cold climates the tenement plan has its advantages; and an outside winter case for four, six, eight, or even ten hives is relatively cheaper than a double-walled hive or even a winter case for a single-walled hive. Cheap panels can be made up out of low-priced lumber; and when suitable hooks and eyes are provided the whole can be assembled around a group of hives in a comparatively short time. A wheelbarrow or a wagonload of packing material can then be shoveled on top.

A couple of beekeepers of Canada told me last winter that the principle is as good in practice as it is in theory; and the best part of it all is that the individual colonies do not have any outside exposure more than the front, if there be two rows of hives. If there be but one tier, there will be an exposure of front and rear, and one side of each end hive. In either case the individual warmth of the clusters or several hives is conserved and not dissipated by so many outside exposures as we have when a single colony is wintered outdoors; and if one colony of a group happens to be a little weaker than some of the others, it shares the heat of the whole bunch.

Another nice thing about the arrangement is that it will work as well in cold as in milder climates. If it is an open winter when the bees can fly, there will be no trouble, as there would be if the bees were in one of the best bee cellars. When it is warm outside, the temperature of the cellar runs so high that the bees become uneasy and die by the thousands.

We believe the tenement hive has come to stay. The logic of last winter has rather jammed that fact into the heads of some located in the colder climates. Of course, we do not expect to have many winters as cold as the last one; but we never know when they will come; and from the facts already gathered it will be seen that the tenement hive is always ready, either for extremely cold climates or a mild one, or for warm winters or cold ones.

Of late there has been quite a tendency toward outdoor wintering; but the cold winter through which we have just passed is discouraging to some in the far north who have been using double-walled hives—not because they were not all sufficient during an ordinary winter, but because they hardly afforded adequate protection during an extraordinarily cold one.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

NO WONDER, says Dr. Kramer, *Schweiz. Bztg.*, 217, that yellow bees flourish better in America than in Switzerland, because America has potash soils.

BEES DESERT watering-places when oranges bloom, p. 435. Isn't it the same thing with any other bloom? I can tell when a flow lets up by seeing the bees begin again on the water-tub.

THE EDITOR of *Deutsche Bienenzucht* counts it of great importance upon introducing a queen to cage first the old queen in the hive a few hours, then put the new queen in the same cage, and in the same place in the hive, and let the bees release her. He says the bees do not know their mother at all, only her odor, and that odor is given to the new queen by the cage as covering her own odor, if I understand correctly. [There may be something in this; but it would be a lot of work to cage and recage queens for introducing. We doubt whether it would pay.—Ed.]

DO BEES sting drones to death? When you see a worker sting another worker you don't have to watch very long before you see the bee curl up and die. Did any one ever see a drone curl up and die immediately after a worker had stung it or pretended to sting it? [We have seen bees make a bluff at stinging drones, but never saw them do the act. It is our belief that, when the honey-flow stops, the drones are simply pushed out of the hives, and that they simply die from starvation. We do not believe that nature has designed that worker bees shall sacrifice themselves as well as the drones, because it is cheaper to starve them than to sting them to death.—Ed.]

I SUPPOSE beekeepers will smile a quiet smile of indulgence upon reading, p. 384, that bees recognize the different spots of playing-cards. And yet—and yet, is it not just possible that bees are guided by form much more than by color? And is it proved beyond a doubt that they can not distinguish at a glance the difference between an eight-spot and a ten-spot just as well as we can? We are too prone to measure every thing by our own senses. One who knows nothing about the keen scent of dogs would likely be skeptical upon hearing of a hound scenting a trail upon the full run. If a creature with four legs is so much beyond us in the matter of scent, may not one with six be just as much beyond us in the matter of recognizing form?

HARRY G. BRANT, p. 417, it must be a very exceptional case when bees trouble boxes of berries. For years strawberries, raspberries, and blackberries have been on my place, the first two part of the time by the acre; and although boxes of berries were freely exposed for hours, I never heard any complaint about the bees. During all these years there must, too, have been times of dearth, and certainly there we were feeding bees this year during the first of strawberry-picking. By the way, A. I. Root, we have a seedling that would interest you. I think it is a little the best strawberry I ever tasted, and one of the largest. Some object that it is not sour enough. [Years ago, when A. I. Root grew strawberries for market in a large way, we had 500 colonies and nuclei located within a stone's throw of the berry-patches, and at an equal distance boxes of berries were placed before they were actually sold; but never once did the bees attack the berries so far as we can remember.—Ed.]

YOU SAY, Mr. Editor, p. 396, that bees of a foul-broody hive would carry the disease into hives near by. I suppose that means that the bees of the diseased colony returned from the field and entered wrong hives. That's worth thinking about, for it knocks out the Baldrige cure of foul brood, according to which bees that go to the field return without any disease. Some error one side or the other. [Perhaps our statement, page 396, was a little strong; but nevertheless, when we had foul brood years ago we were in the habit of examining the combs of near-by colonies that faced in the same direction — especially that colony which had an appearance and location almost exactly the same as the one affected. If the diseased colony in the first place was a bad one, we were almost sure to find a few stray bad cells in the nearest of two or three hives facing in the same direction.]

We have been a little slow about recommending the Baldrige method of treatment, for the very reason suggested by you. It has been our preaching and our practice, that, the sooner a diseased comb is gotten out of the hive, the better. The only time we have recommended the Baldrige treatment is when a great deal of brood in the apiary is involved, the sacrifice of which for a few bad cells in the comb would be considerable. Where only occasional colonies are affected we would treat at once; that is, we melt up every comb containing a diseased cell or two, or more.—Ed.]

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

The weather during June and July was the coldest for 21 years.

* * *

Five big meetings for beekeepers have been arranged by the State Association, acting with the University of California. It would have been a great help to have these meetings advertised in the bee journals in advance, but the date was not fixed in time for that.

* * *

With a fine-pointed medicine-dropper I sucked the honey from orange-blossoms, measured it by drops, and computed it by apothecaries' rules, on an estimated number of blossoms per tree. The result was an amount so large that, for the sake of my veracity, I will not give my figures.

* * *

A county association has been formed in San Bernardino Co. to meet alternately at San Bernardino and Redlands on the first Monday evening of each month. The writer is secretary for the present, and those wishing to join and help with the work will kindly communicate with him.

* * *

As I look at the pictures of the remains of Mr. Atwater's apiary, destroyed by fire, page 483, Aug. 1, I can not help thinking of the many apiaries that have met a like fate by brush fires in California, all of which could have been prevented by keeping weeds, grass, or other dead vegetation out of the yards.

* * *

The monthly crop report of the California Beekeepers' Association has been a great success. The reports were within themselves well worth the annual dues charged for membership. I believe, however, more local data should be given. Beekeepers seem especially anxious to know what the different localities of the State are doing.

* * *

The other day I had occasion to shift the lower story of a hive to the top, setting the super beneath. The lower story was painted white, while the super had been primed with oil and yellow ochre, and it was amusing to watch the bees alight at the bottom of the white story, after they were shifted, and try to find an entrance between the two sections of the hive. It suggested to me that color as well as position has a part in helping the bees to locate the entrance.

While in the act of introducing an imported queen a few days ago I discovered a well-developed case of American foul brood in my back yard. This is the first case I have had for four years, and it has undoubtedly been contracted from diseased bees near by, of which I am sure there are many. From information that I have gained recently I am led to believe that there are hundreds of diseased colonies in San Bernardino County.

* * *

I quote the following from the report of the San Bernardino Co. grand jury:

We have examined the books in the office of the County Bee Inspector, and find that the principal charge made by the bee inspector is for office work; but it appears he spends very little time in his office. After investigation had, we would report that the present County Bee Inspector is not conducting his office in an efficient manner, and we would, therefore, recommend that the said office be declared vacant by the board of supervisors.

The following quotation was taken from the *Daily Facts* a few weeks later:

The office of County Bee Inspector, graced by "Bob" Heron, was declared indefinitely vacated although Inspector Heron presented a lot of documents to show what a good man he was.

* * *

I have been receiving queens from several localities the past few weeks. Some have been in cages entirely too small and with too few attendants accompanying them. One which I received had but eight attendants, and three of those had died. I waited almost two months for the arrival of one order, and several weeks for another. Becoming disgusted at waiting so long, I tried a third breeder, ordering by wire, and had my queens introduced the 6th day from date of my order, though they came more than 2000 miles through the mail.

* * *

Louis H. Scholl, page 434, July 15, tells why Texas beekeepers failed after having such bright prospects. Nearly all of us can sympathize with Mr. Scholl and his Texas neighbors, having traveled the same road ourselves at different times. The great majority of California beekeepers have had the same experience this year, but they should not be inclined to give up, though it is discouraging indeed. I should not be surprised to see a good crop next season; but any way it will be necessary to keep a "stiff upper lip" and take good care of the bees, as we may "hit it hard" again some day. The beekeeper who has his hives full of bees is the one who will reap the greatest reward.

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

A letter from one of the best-known apirarists in Illinois says, "We are still feeding our bees, and expect to for another month, as there is hardly a clover blossom in our section, and we can get no honey till the fall flow." While conditions were not so bad in our section, yet a statement like that in the latter end of June made me think that we should be very thankful that things are as good as they are.

* * *

Clover has been very scarce in many parts of Ontario this year; but prospects are exceptionally good for another season, as the spring "catch" is one of the best for many years. Alsike seed is very high in price, and the many fields now covered with a growth of this clover will be left for seed another year. Given a normal winter, things certainly look good for next season; and beekeepers will, no doubt, see that their stock is put in good condition for the winter, whether it be a mild or severe one. Extra good preparation does no harm, even if a moderate winter should come; and if extra severe, the precautions taken will repay tenfold all attention given.

* * *

Unseasonably cool weather during all of basswood bloom prevented much honey being gathered, even if basswood did make the best showing for ten years. However, basswood lasted nearly three weeks, and considerable honey came in along with the thistle—the latter plant yielding better than for some time. Prospects are now good for buckwheat if we get warm weather; and, by the way, we have had less warm weather this past summer than the "oldest inhabitant" can recall during any other year. However, a medium crop has been secured by all I have heard from; and as bees are in fine condition there should be no great kick coming from the fraternity, especially when prices are good and the demand practically unlimited.

* * *

Recently we have seen some statements in the bee journals which would go to prove that spraying fruit-trees while in bloom is not injurious to bees. While I am at all times open to conviction, it will take a good deal of substantial evidence to convince me that bees do not suffer severely when spraying is done at this time, and I believe a great deal of evidence, thorough-

ly reliable, can be given to prove the opposite. Indeed, I think it is very unfortunate that the non-poisoning theory should be given any prominence, for some men would be only too glad for a chance to go back to the old way. I say "some men," and by this I do not include the well-informed fruit-grower, as he knows that the bees are his friends, and will take no chances on killing them on the blossoms, especially when he has, in addition to this, learned that the blossoms are injured when sprayed while in full bloom.

* * *

On page 166 Will Jensen makes some astounding claims for the plan he advocates for doing away with spring dwindling. Being as far south as Texas, I am made to wonder how it is that he has so many weak colonies as to be able to figure out that he saves 97 per cent each year by the plan. If I understand the plan correctly, he compels the bees to extend their brood area by dividing the combs with a sheet of foundation—the last thing the most of us would think of—well, he may be all right for his "locality;" but, as the Scotchman would say, "I hae my doots." [If we are not mistaken, Mr. Jensen's experience has been in Virginia chiefly, this year being his first in Texas.—ED.]

* * *

Weather has been very hot during past few weeks, and that reminds me of a rather amusing thing that happened in Toronto last week. Needless to say, many of our American cousins have some queer notions as to the condition of Canada, climatic and otherwise; and, judging by letters I have received, many think we never have any warm weather up here. Any way, last week the International Association of Police Chiefs held their convention in Toronto, and Secretary Carr took the care, when sending out circulars of instructions to delegates that were coming, to advise them to bring heavy underwear and light overcoats with them. Many of them did so, and one can imagine how they felt about it when they found the heat so intense. The chief from St. Louis said it had his city "beat to a frazzle," to use a current expression; and when next time they visit Canada they will hesitate about following their secretary's advice, even if the convention should be held in January.

WESLEY FOSTER, Boulder, Colo.

* * *

* * *

* * *

Mr. Harvey, of Montrose, told me that he had lost fully \$2000 by fruit-growers spraying for codling moth when the trees were in bloom; but that, during the last few years, the fruitmen were learning better when to spray. I do not know how well informed beemen are in other places; but the majority of Colorado specialist beekeepers do not blame the fruitmen for killing their bees with arsenical spray when the trouble is foul brood. Our Colorado men are pretty close observers.

Conversations with Doolittle

At Borodino, New York

BEES TEARING DOWN QUEEN-CELLS.

What causes bees to tear down queen-cells about the time the young queen larvae are changing to the pupal form? I have been having trouble in this way during the entire season, especially since the flow of nectar has stopped. I have tried caging the reigning queen, or fastening her to one side of the hive with a queen-excluder, or placing the cells over a queen-excluder on a strong extracting colony; but the bees seem to tear down the cells about the same, no matter where I try to keep them. I have fed the bees liberally, but I do not see that this makes any difference. Then I have used black bees, hybrids, and pure Italians; yet the destruction goes on all the same, until I have become nearly discouraged. Can you tell me what causes this trouble?

There are several causes for bees tearing down their queen-cells after they have built them and have gotten them all sealed over. The most common one is a sudden stop in the nectar flow from the fields, which cessation, if long continued, results in the destruction of all queen-cells, and many times the killing-off of all drones. And I may add here that, if feeding is not resorted to as soon as this flow of nectar ceases, it will have little effect toward saving the cells after the bees have once decided on tearing them down, although it will generally preserve the drones. So the queen-breeder should be constantly on the lookout so that he may know just when there is a stop in the secretion of nectar in the flowers. For this purpose, as well as for many others, a hive having a strong colony should be placed on scales, so that a glance each day may confirm his observation of conditions.

The next most common cause for the destruction of queen-cells is that a virgin queen gets into the apartment where cells have been placed for safe keeping. They sometimes appear where it seems impossible. Once I opened the hive of a colony which had three frames of cells in different stages of completion, in order to take out the frame having ripe cells, which I wished to use. While stopping to do a little other work I set one of the other frames having queen-cells down outside of the hive. It remained there perhaps two or three minutes, when it was returned and the hive closed. Two days later I went to this hive, and my surprise can be imagined to find some forty-five of the fifty-two cells I had left there two days before all destroyed. It was about two o'clock when I was there the first time, this being about the time queens take their flight; but it did not seem possible that any virgin queen could have entered the hive during the time it was open.

The hive standing next to this colony

had a virgin which was old enough to fly out, and I soon decided to open this hive and look for her. The moment I lifted the covering the mournful humming noise made by the bees indicated that they were hopelessly queenless. It then dawned on my mind that this queen was out two days before, and had divined that the colony I had opened needed her presence there, so she had either alighted on the frame while it was standing outside the hive or had gone in at the top unnoticed. This queen had a little dark spot on one of her sides, so I at once looked over the upper hive where the cells were destroyed, and soon found her there. This was one of the most far-reaching losses I had ever had up to that time, and I was greatly inconvenienced and chagrined over the matter. But I take it that neither of these cases is identical with the experience of the correspondent, as his seems to be a long-drawn-out difficulty.

Up to about ten years ago I could account in one way or another for the tearing-down of queen-cells. But there came a year when, after about the 10th of August, colonies in which I had cells stored would begin to tear down a few, from two to five or six, doing so gradually from the time the queens in them arrived at the pupal form till they were about to emerge from their cells. And they would do this even in queenless colonies. I fed them right along and looked carefully for any virgin queen that might have gotten in, but all to no avail. All the plans which I had used successfully for twenty years failed. I had no trouble in getting queen-cells started; and, as a rule, sealed, but soon after this the bees would begin to tear them down slowly, till I got behind in filling orders, and became exasperated. While lying awake one night bemoaning this state of affairs the idea of making such colonies hopelessly broodless, all but the queen-cells, occurred to me. The next day I tried the scheme, and all worker brood, whether sealed or unsealed, was taken from hives having queen-cells stored therein. This settled the matter, and since then I have had no trouble of this kind.

Bee-stings for Sciatic Rheumatism

I have had sciatic rheumatism for two years. I am applying the stings daily on my arms, and am meeting with good results. I will report later.

A SUCCESSFUL QUEEN-CAGE CANDY MADE WITHOUT HONEY

A Substitute for Sealed Honey During the Winter

BY ARTHUR C. MILLER

He who makes available the principles embodied in a good idea is quite as much to be honored as he who originates it; and he who makes practical what another has only partly developed is also a benefactor. Sometimes necessity is quite as often the foster-mother of a half-grown plan as she is reputed to be the mother of invention. Apropos of which is the result accomplished by one New England queen-breeder when bee-disease laws and postal rulings bade fair to hamper his business seriously. Reference is made to the work of Mr. O. F. Fuller, of Blackstone, Mass., a persistent sort of chap who seems to have a way of making good with ideas which some one else has *not quite* won with. Confronted with the troubles alluded to, and hearing of a bee food or candy containing no honey, he sent to England for samples and recipes. In due time both arrived, together with a feeder in which to use the candy. But the candy did not behave according to rule or expectations, having a faculty of getting too hard or too soft. So, instead of guessing, Mr. Fuller hies himself to an acquaintance who is a professional candy-maker, shows him his bee-candy and the recipe, tells him the trouble and what he desires to accomplish. The candy-maker very cordially tells him all he can about it, and also tells him what ingredients to increase or decrease in experimenting. At the problem Mr. Fuller goes with his usual persistence, and the result is success, as might be expected. He has a candy which he and other queen-breeders have been using all the season with perfect success, and not a drop of honey is in it. The recipe has been very generously furnished by Mr. Fuller, and here follows:

Granulated sugar, 5 lbs.; coffee A sugar, 1 lb.; glucose, 1 lb.; water, 1½ pints; one level teaspoonful of cream tartar.

Boil until the temperature reaches 240 degrees F. for summer use, or 232 F. for winter use. Do *not* stir it while cooking. When it reaches the desired temperature, remove from fire and let it cool until the finger can be held in it for half a minute, then stir and stir until it is so thick that it will barely pour out. It may then be run into molds, feeders, or cages. If kept

in a closed receptacle it will not change for an undetermined period, the writer having some made last February which shows no change yet, and Mr. Fuller says it will keep indefinitely.

Any thermometer which will register up to 300 degrees F. will do to test the cooking syrup; but a regular candy-maker's thermometer is better, if one plans to make much candy.

Queens have been successfully shipped pretty much over this country and Canada and to England with it. Full colonies shaken from their combs have been shipped with no other food than this candy, and with the best of results.

He and others also use this candy in feeders as a winter food, and many Massachusetts and New Hampshire beekeepers are high in their praise of it.

Last winter, which we all know was a severe one, it was used in quite a number of cases where the bees had so little honey it could be called none, and the colonies supplied with the candy wintered excellently. Incidentally, a very few pounds of candy took the place of many pounds of honey.

The feeder used for the purpose is an English device. As made and used by Mr. Fuller, it is a rectangular frame made of strips of wood about two inches wide. These are grooved about ¼ inch from one edge, and into this groove a pane of glass is slipped, making a box with a glass bottom. Mr. Fuller's feeders take a pane 6x8 inches. These boxes are filled with the candy when it is hot and soft, the candy coming within about a bee-space of the top. When it is cold it can be handled like a block. Each feeder holds about 2½ lbs.

Two or more of these are inverted over the top of the brood-frames, and covered with cushions or some similar protection. The bees have access to the whole of the now under surface of the candy. No moisture or air can get at the edges or top of the cake, so it neither hardens nor softens. By turning back the cushion the beekeeper can readily see how much of the food is consumed.

Mr. Fuller does not claim any of this as original; but he does know that he has made a success in the compounding of a candy for bees which is without honey. He has given to the old candy-feeding system the one or two little kinks which it needed to make it all that can be desired. To the queen trade, and thence to all beekeepers, he has brought a boon in the shape of a thoroughly practical and successful food

which is free from all the dangers of a candy containing honey.

Providence, R. I., Aug. 13.

[It is to be hoped that a candy of this description may come into general use; for, aside from the danger of disease, honey is not always uniform, and, furthermore, it takes up moisture so rapidly that the candy containing it is likely to become disastrously soft in damp warm weather. We should think that the glucose candy would be an improvement in this respect, but we may be mistaken.]

We wonder whether the commercial glucose purchased in this country would be satisfactory. The so called corn syrups evidently would not, because of the varying amounts of cane sugar which they contain.—Ed.]

LIME DOES DRY A CELLAR

BY JAMES M. MUNRO

In reviewing GLEANINGS, Feb. 15, 1911, p. 110, I take decided objection to the heading of an article by F. L. Huggins, "Lime in the Cellar will Not Dry the Air," and what makes it the more misleading is that he uses terms in chemistry to substantiate his position. I have worked in a lime trade for the past 40 years, and I know of no better agent than stone lime (CaO) to absorb moisture unless it may be fire.

For those of us who have to winter our bees in a clay cellar in a severely cold climate I consider lime a most useful article, as it dries the air and does not give off any poisonous gases as some methods of temporary cellar heating do.

OTHER USES OF LIME.

How many know that air-slacked lime, dusted into places where it is not convenient to whitewash, is death to mold? How many farmers know that, if they are caught in a shower with a load of hay, a light sprinkle of air-slaked lime will prevent it from turning musty, and that it is a benefit rather than an injury to the stock? How many know that a dusting of air-slaked lime applied to potato tops on a damp morning in a summer fog will prevent potato blight?

I begin the prevention by dusting with lime as soon as the potatoes are cut. This not only lessens the chance of the seed rotting, but is a cheap fertilizer, and a preventive against grubs. Then when I harvest my potatoes I sprinkle an occasional handful as I empty them into the cellar. I haul them directly from the field and have no more handling of them, only

as required for sale, use, or planting. Before I adopted this plan I used to have to sort the rotten ones out at intervals during the winter. I put the lime treatment to the test in a small way before adopting it wholesale to hundreds of bushels as I do now. Upward of 20 years ago I had some Beauty of Hebron potatoes, and many of us know how susceptible they were to rot. They began to rot, and I put one lot in a box with lime sprinkled in. The others I put in a box without any lime. The unlimed ones rotted so badly that they became a mass of corruption. The lime-treated ones came out dry; and wherever a spot of disease had begun it had dried up.

I consider no farmer's home to be well equipped without a barrel of lime stored in a dry place

A GOOD RECORD IN A SMALL CELLAR.

A year ago I was so beset with work that I failed to weigh any of the hives. Many of them felt too light. Four were nuclei. So, naturally, I risked it. I piled them in the cellar like so many rows of stovewood. The size of the cellar is 9x11 feet, 6 feet high, raised 16 inches from the floor, so I think you will smile at the crowded aspect 84 colonies would present. The winter, of course, was very severe, and there was very little snow here. The temperature frequently fell to 40 and even 60 degrees below zero. I began taking cellar notes Jan. 2, which are as follows:

1912.	Jan. 2.	Tem.	26	degrees	above	zero	in	cellar
"	"	11	"	28	"	"	"	"
"	"	16	"	33	"	"	"	"
"	"	30	"	36	"	"	"	"
"	Feb. 12	"	34	"	"	"	"	"
"	"	17	"	44	"	"	"	"
"	"	28	"	37	"	"	"	"
"	March 4	"	36	"	"	"	"	"
"	"	20	"	39	"	"	"	"
"	"	21	"	41	"	"	"	"
"	"	25	"	42	"	"	"	"
"	April 4	"	48	"	"	"	"	"
"	"	10	"	48	"	"	"	"

On April 12 I set the bees out on their summer stands. The night temperature outside was 21 above zero. The bees gathered the first pollen on April 23 from black-alder bushes.

Now with all this abuse you will wonder how many came out alive. Out of the 84 colonies put into cellar, 78 came through in good order; and what I am surprised at is the small quantity of stores they consumed. I use the ten-frame Langstroth hive exclusively.

Slate River, Ont., Feb. 2.

[If we understand Mr. Huggins correctly, his idea was that the lime would not permanently dry the cellar unless moist air from outside could be kept from coming in again. However, since most cellars

that are wet are wet because of poor drainage, etc., it would seem to us that the lime would be of advantage.—ED.

WINTERING IN SINGLE-WALLED HIVES IN KANSAS

BY ARTHUR V. SMALL

I winter my bees out of doors in single-walled hives, protected in the following manner: Two frames are removed from each hive. A piece of shingle, with a half-inch strip under each end, is placed crosswise over the frames, which provides an upper passageway for the bees from one comb to another. A piece of oilcloth is placed over this, extending nearly to the bottom-board on each side of the frames. The space between this oilcloth and the side of the hives is filled with about fifty thicknesses of newspaper which are suspended from a strip similar to the top-bar of a frame. The papers extend to within an inch of the bottom-board. It is important that they do not touch the bottom-board, for the moisture which condenses on the back of the hive flows over the bottom-board to the entrance, and these papers must be kept dry. A super filled with newspapers and shavings gives protection above. With this arrangement, practically all of the moisture is condensed on the ends of the hive where it can run off without doing any harm.

The Hoffman frame gives a double-walled end for the upper part of the brood-chamber, and the bees do not suffer seriously in this locality from the unprotected hive ends. In very cold weather, little icicles will form at the entrance; but I have examined the packing at various times during the winter, and have always found it dry. I have followed this method for the last four years with very good results. TAKING THE TEMPERATURE OF THE HIVE.

This winter I placed an 8x10 glass half an inch above the frames of a ten-frame hive packed as above, and beneath this glass a thermometer lay on top of the frames. By pulling aside the super packing, the thermometer could be read through the glass. After a long cold spell in January the outside temperature dropped to 19 below zero. At the same time the thermometer above the frames registered 32 degrees. That afternoon the outside temperature rose to 5 below, and the hive thermometer read 39. I have watched this thermometer all winter, and a zero temperature will send it down to 36 or 38 in the early morning, but during the day

the bees raise the temperature to 42 or higher, and move about freely on the top-bars, the entire cluster being below the top-bars. On days when it is warm enough for the bees to fly, the hive thermometer registers about 70.

With this difference in temperature between the outside atmosphere and the air above the top-bars of a hive I consider top protection almost a necessity, and protection on the sides or ends a decided advantage as long as the hive can be kept dry.

A piece of six-inch board with two V-shaped notches cut in the under side, leaned against the front of the hive, and fastened with a small nail, gives good protection from cold winds and sifting snow.

Topeka, Kan.

[This is virtually double-walled wintering. It amounts to the same thing as a brood-nest covered with a good many thicknesses of paper, with this difference: The paper is *inside* rather than outside of the hive. Right here there may be an advantage.]

With regard to the question of taking temperature, see answer to Mr. Ben B. Edgerton in this issue.

The matter of upward ventilation or sealed cover and ventilation only from the entrance is a mooted question. For very cold climates we generally consider that upward ventilation plus entrance ventilation gives better results than a sealed cover and entrance ventilation only. In the milder climates many prefer the last named. We have had excellent results with it in our locality, taking one year with another.—ED.]

WINTERING IN A DOUBLE-STORY HIVE PACKED IN LEAVES

Importance of so Placing the Stores, that They will be Available to the Bees

BY F. H. CYRENIUS

Much has been said about the necessity of using large frames to accomplish satisfactory results when wintering bees out of doors. It is a well-known fact to the observing beekeeper that bees during very cold weather do not shift their cluster from side to side, but will consume all the honey in the combs containing the cluster, and will then starve with plenty of honey on each side of them. Thousands of colonies starve in this way.

This condition could be remedied if this honey at the sides were arranged directly

over the cluster. In order to accomplish this plan most easily, remove the two outside combs of honey on each side, and put in their place empty or partly filled frames. This leaves very little honey in the brood-chamber, but nearly as much as the bees would have consumed under the conditions given above.

In an upper chamber place the four frames of honey in the center of the chamber, filling each side either with partially filled or with empty combs, as one may happen to have on hand.

For the eight-frame hive I would use about five frames of solid honey, for the ten-frame hive, six. This amount ought to carry the bees until another year's honey comes in. This plan has settled for me the question of deep frames, of cluster room, and of starvation.

The protection used is, first, a paper wrapping; then a box that is a little larger than the hive is set down over the hive like a deep cover. The box should be deep enough to come down partially over the lower hive. This box, before being placed on the hive, should be provided with about two inches of packed leaves or fine straw. I prefer leaves. Fill the box about three-fourths full of leaves; level them nicely, and put a follower on them. By stepping on the follower the leaves will pack down sufficiently so that they will remain in place while the box is turned open side down on the hive. Place the hive cover over all and weigh down with a good-sized stone.

Those colonies which were wintered out of doors by the method just described came out in perfect condition—even better than those in the cellar. I had some fear of moisture accumulating in the leaves; but three winters have shown that it does not.

Oswego, N. Y., April 13.

[As our correspondent says, it is very important that the stores be promptly placed with reference to the cluster in the hive. In our locality our bees will make the proper disposition of them if they are left alone; that is to say, they will form a winter nest in the front part of the hive just above the entrance, and two inches or more below the honey. At least that is the rule that has exceptions. In the Langstroth hive, as the stores are consumed, the bees move upward and then backward.

We would doubt, however, the advisability of placing stores in two stories, as here recommended, for *all* localities. It is interfering with nature, even though it is an

effort to imitate it by placing the stores above; but the tendency will be for the bees in some cases, at least, to go up into this upper story; and if they should consume all the stores there, they might be left high and dry. The four frames of honey in the upper chamber might be enough, but in our locality we should be afraid that bees would locate in this upper part, eat away the stores, leaving a considerable quantity in the lower hive which they would not get.

Much depends upon the colony. Some bees will locate in the top part of the hive and some in the bottom part, where two stories are given. While our correspondent might be able to arrange the stores properly, the average beginner would complicate matters, we fear.—Ed.]

PACKING BEES ON THEIR SUMMER STANDS

Providing a Passageway Above the Frames

BY C. A. BUNCH

It seems to be an established fact that, to pack bees on their summer stands with upper ventilation, is by far the safest plan for the beginner, even though the packing does get wet from the breath of the bees.

Having had from 60 to 80 colonies of bees packed on their summer stands each winter for the last seven or eight seasons, I find that, in order to winter bees successfully without upward ventilation, it is well to allow them to cross above the frames at will. This is possible if a small $\frac{3}{8}$ -inch stick is placed across the frames before the board is laid on, with plenty of good packing above, well pressed down. If this is properly done it is impossible for frost to gather above the bees, for they will keep the board above them dry and warm. The consequence is that the bees will not be affected by the cold, and a considerable amount of stores will be saved thereby for use when rapid brood-rearing begins in the spring. But until toward spring, in the climate that we have in Indiana, the entrance must be about $\frac{3}{8}$ by 8 or 9 inches, both for ventilation and to keep the hive dry.

Later in the season the entrance is made smaller in order to allow brood-rearing; but if a sleet should chase the front of the hive so as to cut off ventilation I pour some hot water along the front of the hives for the purpose of melting the ice.

Lakeville, Ind.

FIG. 1.—Home of Geo. H. Kirkpatrick, Rapid City, Mich., "built by the bees."

CELLAR WINTERING

Size and Construction of Cellars

BY G. H. KIRKPATRICK.

Although I established my first out-apiary over 25 years ago, I have always wintered my bees in cellars, of which I now have three. My experience is that the size of the cellar to be used depends upon the number of colonies to be wintered. Each colony must have not less than 15 cubic feet. In this northern climate our soil is generally sandy and the cellars dry.

I place my bees in the cellars, usually, about the first to the tenth of November. It sometimes happens that we have a few

inches of snow at this date; and then when moving the bees from their summer stands to the cellar I use a pair of light hand sleighs, seven feet in length, Fig. 2. We begin at the further end of the yard from the cellar; get the sleighs in place, then gently press a little snow along the entrance of the first hive to close it. The cover is then removed; a quilt is made from two layers of carpet, and placed over the top of the hive. In this way five colonies are prepared and set on the sleighs, and drawn to the cellar and placed as shown in Fig. 3.

The windows are fitted with wire screen, and are left open to admit a free circulation of air until settled cold weather comes, when they are packed with straw which is

left until about March 15. After this the windows are left open except on warm days, when they are darkened. Should there be no snow at the time of setting the bees in the cellar I use a wheelbarrow instead of a sleigh.

I have one cellar in heavy clay soil, and

FIG. 2.—Hand sled used in carrying bees into the cellars.

FIG. 3.—How the hives are stacked up in the cellar.

this one is damp, so I use a tray built of lumber sized to $\frac{1}{2} \times 3$ inches. From this stock I make rims just a trifle larger than the hive-body and put bottoms of burlap on them. These trays are then filled with kiln-dried planer shavings, and placed over the hives on removing the cover, as in Fig. 4. The shavings absorb the moisture and retain the heat, so that the bees winter well. The temperature should be a little higher than that of a dry cellar. I prefer a temperature of 43 to 45 degrees in a dry cellar, and 48 to 50 in a damp one.

It is my practice to *carry* the bees from the cellar in the spring to avoid the jar that they would receive if wheeled on a barrow. If the bees have wintered perfectly, and are quiet, it is my belief that

FIG. 4.—Trays of dry shavings set over the hives in the damp cellar.

they should be left in the cellar until they can gather pollen. In this climate bees gather the first pollen about April 10th to the 15th. I usually carry the bees out on a cool afternoon when the indications are that the following day will be fair. On the night previous to setting the bees out, I open all doors and windows. The cool air has the desired effect of causing the bees to cluster closely. To prevent them from flying while being moved from the cellar I provide a few strips of cotton cloth; dip them in water, and gently tuck them into the entrances, removing them as soon as the hives are located. At the time of placing the bees on their summer stands I leave the quilts on, placing a piece of tarred felt over each one, large enough to project one inch all around. Over this felt I put the regular cover.

Rapid City, Mich.

PROPER WAY OF MANIPULATING AND WINTERING BEES OUTDOORS

BY G. C. GREINER.

While giving a description of the cover-picture of *GLEANINGS*, Dec. 15, 1911, the editor refers to a former article from my pen, in which I described the management of outdoor wintering as I practice it. I disclaim any semblance of my management and outfit to the arrangement which this cover-picture would suggest, for it is extremely faulty.

It is not an easy matter to shift bees from one place in the apiary to another, without causing more or less confusion, mixing, and mingling of bees of different colonies, which is always accompanied by some loss of bees. It requires the most careful application of what years of observation have taught me to shift my bees from their summer position to their winter quarters with positively no confusion nor the loss of a single bee. We can change the appearance of a bee home with endless variations in color, shape, material, etc., without any detrimental effect to the bees except, perhaps, a little hesitation for a few times on entering when coming home, if the location is not changed; or we can change their location very gradually, not more than the width of the hive, every three or four days (but these must be *flying* days), and cause no inconvenience to the bees, if the aspect of the home remains the same; but change both at the same time and an undesirable disturbance with loss of bees will be the result. Any manipulation that produces this state of affairs is faulty.

G. C. Greiner's apiary in winter quarters. The hives are gradually moved together in groups, and then the sheds set up over them.

The editor says: "It was his practice, however, to move the bees from the several stands in the bee-yard to a new position under the shed." This gives a wrong impression. Practically I never move my bees under nor into the shed; but I move the shed around the bees. These sheds are made in sections for that purpose. Sides, ends, bottoms, and roofs are adjustable, and held together by square-headed wood screws. The only moving or shifting of bees I ever do is done early in the season, right after the last honey-flow, and very gradually, and not, as the editor says, "late in the season and all at once." That would surely cause a general mixup on the first flying day after the operation.

To explain fully the proper way of moving bees successfully—that is, without any loss of bees—I refer the reader to the accompanying drawing. The upper row shows ten colonies as I work them for extracted honey during the season. They are equally spaced with two feet in the clear between the hives.

The second row shows the same hives after the first shift is made. The four hives, 2, 4, 7, 9, are moved their width toward the center hives 3 and 8. After two or three days (and, of course, I mean flying days), when these shifted colonies have again become accustomed to their new location, the end hives of each section of five, represented by the figures 1, 5, 6, 10, may then be slightly moved toward their respective centers. Under no consideration should these latter be shifted at the same time when the first shift, Fig. 2, is made. That would bring their new stand too near the stands of those just moved, so that more or less mixing up would be encouraged.

The third row shows the ten colonies in position ready for the sheds. If carefully managed, and if the shifting has been done according to the hints

here given, they should arrive at these places without the loss of a single bee.

As I said before, I begin preparations for the winter arrangement as early as the season's work will permit, aiming to give the bees one or two weeks of open flying weather before they are housed for the winter. Then when the sheds are brought into requisition, every colony remains on the identical spot it occupied before the transformation took place. Although the appearance of their homes is completely changed, they are so well acquainted with their location that their first flight from the sheds is as normal as any flight during a honey-flow from their summer position.

The photograph shows the same bees in winter quarters, of which a summer view was given on page 430, July 15, 1911.

It will be noticed that my bees have no protection in the line of windbreaks outside of the sheds; but I am surrounded by orchards, groves, and shade-trees that

FIG. 1.—Detail of the France outside winter case for single-walled hives.

form at least a partial protection against our northern climate. However, I have great confidence in my sheds. They are positively water and frost proof, allowing from two to three inches of chaff packing at the sides, and from six to eight on top over the sealed cover. I can not say that I never lose *any* bees in these sheds. I do lose more than I wish I did; but I never have frosty or moldy combs, except as I find them occasionally in depopulated hives.

It will be noticed that the summer stands are placed on the roofs of the sheds. This is done to keep the ground picked up, to furnish an out-of-the-way place for storing, and as a precaution to prevent the roofs from blowing off. The latter are in no way fastened to the side wall, being held in place only by close-fitting cleats.

On the morning of Jan. 5, 1912, with the thermometer at 3 below zero, I examined a few of my sheds, with gratifying results. By simply raising the roofs and pushing my hand through the chaff until it came in flat contact with the hive-cover, I found the temperature of the latter far enough above the freezing-point to prevent any formation of ice on

FIG. 2.—The winter case in use.

FIG. 3.—The France quadruple double-walled hive.

their under side. In fact, the sensation was surprising. A decided degree of heat could be noticed.

LaSalle, N. Y.

[We gladly accept your correction as to your method of moving your bees. The plan you have outlined in your diagram is perfectly feasible. The plan of winter-

ing bees in tenement hives is coming somewhat in favor in Canada. In fact, during the last severe winter where they had bees in such hives, they came through in remarkably good condition. The tenement-hive scheme, while it apparently involves the moving of a large number of hives a little at a time, effects an economy in winter protection over the double-walled in-

FIG. 4.—Section of home yard; some of the hives appear tilted, but such is not the case, as the snow is drifted more in some places than in others.

Chrysler's fence having loose boards that are removed during the summer to give more ventilation.

dividual hive. Moreover, it gives a greater protection than any single hive could afford, because the bees of the several hives contribute their individual heat to the entire bunch. For very cold climates, the arrangement here described, or the one by Mr. France next described, or yet the one used by Mr. R. F. Holtermann, as shown in *GLEANINGS* for Nov. 15 last, may be used to very good advantage. It is a good time now to make up the tenement-hive panels, and thus be ready when cold weather comes.

Mr. Cavanagh in his article in this issue (page 556) says that in an arrangement that he used similar to this, the strong colonies drew from the weak. It would seem as if there might be a difficulty right here. How is it with you?—Ed.]

a chance to have a small flight—some of the time when it is thirty to forty below zero. If a colony in a single-walled hive is left out exposed to all these changes it is almost sure to perish.

Our single cases have two inches of space around the sides, and about a foot of space above the hive, all of which is packed either with leaves or fine straw. Over the top of the hive is placed a cap having about an inch space underneath, so that the bees can secure honey in outside combs with ease. In putting this together, notice that the sides are held together by pins at each corner. The entrance is provided with an entrance-block and storm-door to keep out the driving snows and winds. Over all is placed a large cover to keep both packing and hive perfectly dry. This I find to be a very practical and successful winter case for single-walled hives.

The larger hives hold four colonies each, with an entrance at each corner. This hive is used throughout the year, as it is double-walled and packed with chaff. It is divided into four equal parts, each colony by itself, and can have supers and standard Langstroth frames according to the requirements of the individual colonies. Over the honey-boards of all the colonies there is room for six to ten inches of leaves or

WINTER CASES FOR ONE OR FOUR HIVES

The France Quadruple Hive for Wintering

BY FRANK F. FRANCE.

Here in the North, where we have cold piercing winds, lots of snow and atmospheric changes, we must find some way to protect our single-walled hives. Nearly every winter we have from five to eight weeks of cold weather before the bees have

fine straw, and a large cover-roof is placed on top.

As long as we need our extra-heavy clothing or overcoats in the spring the hives also need "overcoats." A heavy building-paper or a thick manila paraffined paper of a light color is best to use in wrapping the hives that were wintered in a cellar. The paper should be folded so as to cover the entire hive except the entrance, so that no drafts can get in. If tied with a string instead of tacking on, it can be used over and over every spring. Black building-paper should not be used, as many times on a cold day, even when the sun does shine, this paper will absorb heat and cause the bees to take a little flight, and, of course, be chilled to death.

Many times in the spring when the temperature is up to forty or more the bees come out and have a fine fly, and at the same time there may be considerable snow on the ground. Here is where I notice that many bees perish; for if they once alight on the snow they become chilled so they can not reach the hive again. I use a fine remedy for this; and that is, simply to scatter straw in front and around the hives

on the snow, so that, if they should alight on the straw, they would not be chilled, but can rest and return to the hive.

If colonies have good young queens in the fall, with more honey than enough to winter on, and are well protected with winter cases, there will be earlier brood-rearing and stronger colonies in time for the honey-flow the following season.

Platteville, Wis.

[Mr. Frank F. France is a son of N. E. France, General Manager of the National Beekeepers' Association for many years, and grandson of the late Edwin France, who was a frequent and valued contributor to this journal in the interval between twenty and thirty years ago. The Frances have always been largely engaged in bee culture; and their quadruple hives, or what some call tenement hives, have been used by them for a good many years. They are no experiment, because they have stood the test of time. The tenement-hive idea seems to be coming more and more to the front—especially in colder climates—so cold that cellar wintering prevails. See editorial.—Ed.]

Snow in abundance in Nebraska—an unusual sight.

A WINTER FENCE HAVING REMOVABLE BOARDS FOR SUMMER

BY W. A. CHRYSLER.

The illustration shows my home apiary with a winter protection and summer fence. The yard is about 65 or 70 feet square, and holds 130 colonies. The fence is made of 7-ft. by 8-in. cull, short lengths, of various kinds of lumber, dressed both sides, and painted to prevent warping, decay, and also for appearance.

The top rim of the fence is composed of narrow strips nailed on each side of the top ends of the stationary boards to keep them straight and to hold the loose boards in place in winter. The loose boards that are put in place for winter have cleats nailed on them to support them on the lower scantling of the fence, and a button just above it to hold it tightly in place. Buttons are also nailed on each edge. In the photo the removable boards that come opposite posts in the fence have been left as in winter.

Chatham, Ont., Jan. 30.

[We are beginning to believe that an open or slatted fence is better than a solid fence for a windbreak around a beeyard. The force of a wintry blast is broken off more by an open fence or shrubbery than by a solid windbreak against which the wind glances upward and then downward, striking the hives. The railroad companies have evidently discovered the same fact when they make open fences to keep the snow off from their tracks.—Ed.]

SWEET-CLOVER HONEY GRANULATES IN THE HIVES BEFORE SPRING

BY LOUIS MACEY.

Our winters here in Ontario are generally dry and sunny, and hoar frost is very unusual. We seldom have much snow, and a sled is an uncommon sight. About 95 per cent of all the bees here are wintered outdoors. I have been packing part of mine every winter for four years and all have wintered equally well with only one or two per cent of loss.

We generally have a warm sunny day nearly every week; and the unpacked bees will fly while very often the others will not. I took chances too much last year and got caught. As the photo shows, none of the hives are packed. During the three weeks of zero, six colonies died and a good many more were badly weakened.

The honey flow of 1911 was good here,

and hives were heavy with honey; but it stayed too cold for the bees to "move over."

I have much trouble every year with our sweet-clover and alfalfa honey granulating solid in the hives. The bees kick out lots of it (in dry hard granules) nearly every spring. I had one colony starve in early March one year. With solid slabs of granulated honey some cells were uncapped and partly emptied, and all were dry and hard. I have reported this before, but never received any help. Is there any way to overcome or alleviate this condition? Of course, it is understood the critical time with this granulated honey is in cold, cloudy, windy spells in late winter and spring, when the bees can't carry water, and when the hives should not be opened.

North Platte, Neb.

[The only way to remedy the condition of candied honey in your hive, thus causing your bees to starve, would be to extract all this honey early in the fall and feed sugar syrup instead. You would gain by this, for you could take away the honey that would bring a larger price than the cost of your sugar. Of course, you would be out your time, but you would be able to save your bees.—Ed.]

SOME EXPERIENCE IN OUTDOOR WINTERING IN INDIANA

All Plans for Packing Hives in Rows Under Tarred Felt Abandoned for the Large Winter Case Holding Four Hives

BY F. B. CAVANAGH.

I well remember reading of the failures and successes in wintering bees, graphically described by the late W. Z. Hutchinson. I confess that some of the schemes he tried seemed foolish at that time; but my past four years of outdoor wintering has cured me of all conceit, so that I willingly confess "I know nothing;" and in order to make a complete confession I will tell of some of the foolish stunts I tried at outdoor wintering in Indiana; also of the wise stunts which did or did not "pan out."

Several years ago Oliver Foster described in the *Review* a method of wintering four to six hives back to back and covered with straw and earth—a board leaned against the fronts, also covered with straw and earth, forming a dark anteroom in front of the regular entrances. Near the top of the hive, a color entrance was cut for flight. Now, Colorado has a very dry climate, while at Hebron the atmosphere is usually moist. We had very cold weather

in the winter of 1909, and the results were very unsatisfactory, for the dirt frozen solid not only left the bees virtually packed in ice, but there was little chance of getting rid of surplus moisture, so that many colonies died of dysentery on sealed combs of honey.

Most of the bees, however, were packed above ground in clamps of six or eight colonies each, with the small entrances facing opposite, and a deep super of leaves on top of each hive. Leaves were piled above and packed between; and a tight roof of tar felt covered the whole. A pole or board for a ridge gave the proper slant to the covers, and tar felt was brought clear to the ground on all sides, and banked with sods to hold it in place, the entrances being cut through the felt. The results were fair to poor, the principal difficulties being that, first, the heat absorbed by the felt caused the bees to fly too much and get lost on cool days; second, the strong colonies drew the bees from the weaker ones so that the strong grew stronger and the weak dwindled out. The bees seemed to think that all of the big black thing was their own hive.

I have also tried packing in single long rows; in fact, I've tried dozens of variations such as standing hives on end, packing several hives deep, etc. The first winter, that of 1910, proved quite a success for the long-row system. Three long strips of felt for back, top, and front of the closely packed row covered the whole, including supers packed with leaves. The winter had been steadily cold, and the spring was cloudy much of the time. Encouraged by my success, I repeated the method during the open variable winter of 1910, and I lost altogether too many bees. It seems that the heat of the felt must have caused the bees to fly too much on days which were bright but too cool. The strong colonies drew unmercifully from the weak, and many a colony did I find reduced to a handful of bees, with the queen on a generous patch of brood, which showed what I might have had if the bees had stayed in their proper hives. Of course I saved a great number of weak

colonies by the Alexander plan by putting them above the strong colonies over an excluder and drawing brood from below where necessary. I had failed during the three years to winter bees as I knew they should winter; my queens were not at fault. The stores had been carefully arranged, and I had worked so hard, and fixed them up so nicely, to no avail.

Thinking it all over I decided to abandon tarred felt and use a better packing than leaves above, for I realized that my bees had not wintered as they should winter for three years. That I must be prepared for a severe cold or mild and variable winter was evident.

Forthwith last autumn I left the majority of the hives two-story with most of the stores above. A deep super was packed with clover chaff, *not leaves*, and the cover put on. The entrances ranged from $\frac{3}{8} \times 6$ to full width; and in some cases $\frac{7}{8}$ by the width of the hive was left. The results seemed in favor of a sealed cover over the bees. A well-propolized quilt came next best, and a loose burlap was the poorest. I prefer $\frac{3}{8}$ by full-width entrance for two-story single-wall hives. The $\frac{7}{8}$ -inch entrances were not so bad, except that the mice got in where they were not screened. We had severe weather, prolonged cold, with the thermometer often 16 to 20 below

The Cavanagh tenement winter case.

zero. Some of the outdoor colonies packed as above showed signs of dysentery, it is true; but many wintered perfectly. The importance of good packing should be impressed; as where hay, leaves, etc., were used in place of clover chaff or similar

packing the loss was heavy. Bees had to be kept warm and dry above by the use of proper packing and a tight board or well-propolized quilt.

Out of the relics of my Michigan experience I revived the Bartlett packing-case and made some improvement in it. The colonies wintered perfectly. Few stores were consumed and the bees were quiet and bright, instead of being filled by eating heavily. Moreover, the honey was clean and dry. The bees can not clog the entrances, and they will not be tempted to fly on cool bright days, nor will they need a flight. Neither mice, cows, nor hogs can do any damage. These cases will cost about \$4.00 or \$5.00 each, or from \$1.00 to \$1.25 per hive; but the saving in stores and bee life pays for them in a season or two. Besides, they made an excellent place to store packing material in the summer.

Strong colonies of young bees having good store room above the frames to pass freely will winter if there is heavy packing above; but it costs honey to do it, as well as bee life in such a severe winter as the past. Therefore I have resolved to pack all colonies generously hereafter, not only above but around the sides, and to use a sealed board or a propolized quilt with space above the frames. The entrance will be $\frac{3}{8}$, and liberal in width; and most of the colonies will be in two stories; and I intend to winter the greater share of my colonies in packing-cases such as I will now describe.

The illustration shows a perspective view of the winter case with a side and end cut away to reveal the floor plan. A framework of 2x4's crosswise, and 1x4's endwise on edge forms a four-inch space for dead bees. It will be apparent that the regular bottom-boards are omitted, as the hives rest directly on the framework. The four hives are packed closely except for one inch allowed between ends on the middle 2x4, which makes packing somewhat easier.

The entrance construction is quite clear. The bees, in leaving the case, must pass through the entrance on the 2x4; thence upward to the entrance in the end of the case. From limited experience I am inclined to believe this a good feature, both in breaking winds and shading from bright sunlight. The end cleats are on opposite sides—one for the cover to slide on, and one for the hive to rest against and hold the packing away from the entrance.

The side packing comes clear to the floor, and may be any thickness desired. Ours

allow three inches on sides, one inch on ends above the cleat, and ten or twelve inches above. The case is made of $\frac{7}{8}$ -inch hemlock, shiplap, with the roof covered with prepared roofing. The covers have a narrow cleat on edge which telescopes over the case, making it absolutely mouse-proof.

The bottom is placed in position, then the hives are set on it; and, lastly, the rest of the case is set up and the packing put in. This is not a small item in favor of this construction over the cases into which the hives have to be lifted.

Hebron, Ind.

[This winter case is very similar to the one used by R. F. Holtermann with such satisfaction last winter and the winter before. See GLEANINGS for Nov. 15 of last year. Other Canadians, including our special correspondent, J. L. Byer are using it, and more, we understand, propose to adopt it. See articles by Mr. Greiner and Mr. France on page 550 and page 554 of this issue.]

We note that Mr. Greiner and Mr. Cavanagh seem to prefer sealed covers. Others prefer upward ventilation. Who is right? See editorial.—ED.]

HOW TO TAKE THE TEMPERATURE OF A HIVE

The Varying Rates Between the Outside and Inside Temperature of a Hive

BY BEN B. EDGERTON

I tried the temperatures of hives somewhat last year and the year before, and I found that one must be careful about the conditions, especially the lag in the temperature. By "lag" is meant the delay that a heavily covered body has in reaching outside temperature. Six inches of dirt and a foot of clover chaff ordinarily cause enough lag in temperature to save our potatoes from freezing. On this account it is hardly correct to take the temperature of a heavily covered hive after only about twenty-four hours of zero weather following a warm spell.

My bees are protected by a deep cushion over the sealed covers, most of the colonies being in four-colony boxes. I think it is a little more accurate to slip the thermometer under the cushion than to put the instrument actually inside the top of the hive. If the slight disturbance raises the temperature inside, the heat hardly has time to penetrate the $\frac{3}{8}$ -inch super cover before the thermometer registers. If the

instrument were inside it might register too high in some cases.

Winter before last, after an outside temperature of 26 degrees for two weeks, and last winter after nine days of zero, I found the tendency of the thermometer under the cushion was to register around 45 or 46 degrees in each case, the lowest temperature I noticed being 38 degrees. Two days later, the outside temperature being 14 degrees, I found, out of five colonies, two that registered 45 degrees and 44 degrees respectively; two 37 degrees and 34 degrees, and one only 28 degrees. Less than two weeks later I found this latter colony dead. The bees starved from being unable to reach the stores. The colony was surprisingly large considering the fate that overtook them, and they were protected fairly well.

Of course it is not safe to make any general conclusion from just a few trials; but until we learn more I suggest this: That 45 degrees is about the normal temperature in the upper part of the hive. If it is much warmer than this, it may be an indication that something is disturbing the bees. If much colder, it is a sign that the colony is too weak for the frames it occupies, or else that the wind hits the hive too hard. If the temperature is below freezing, the bees are in bad shape.

With reference to a well-protected colony keeping the temperature in their hive only one or two degrees above the outside air, I will say that, in some of the hives, the temperature was 43 or 42 degrees above the outside air on a day when it was 4 degrees above zero near noon, following a morning when it was 16 degrees below. Even the poor starving colony that was making its last stand against death kept its hive about 14 degrees above the outside air. Hicksville, Ohio.

[The point is well taken. The reader will see that we took this into account—that is, "lag" of temperature of a hive, when we reported temperature readings taken last winter. See page 78, Feb. 1, and page 125 for March 1.—ED.]

it be easy of solution in our changeable and uncertain New England climate. During a mild or average winter, outdoor colonies fare best; but in the severe winters we sometimes have, any reasonably good cellar would doubtless give better results.

The essential feature of this method is a separate case for each hive, of sufficient size to allow four inches of packing on all four sides and twelve inches on top. There is no protection on the bottom. These cases are made of rough lumber one inch thick, with a cover of the same material, that telescopes down two inches all around. It is covered with tarred roofing paper, and there is sufficient slope to carry off all water. Two boards, just wide enough to allow the empty case to be set down over the hive with the cover off, are nailed on the bottom of each side. A loose board of the proper width is used back of the hive to prevent the packing from falling through, and the front board is three inches above the entrance. The super covers are sealed down tight, and no provision is made for ventilation of any kind anywhere except at the entrance, which is the regular $\frac{3}{8}$ by 6 furnished with the hives. I have never been able to scrape out more than a cupful of dead bees during any winter from one colony, and there have been two occasions when I was satisfied that the bees came out stronger in the spring than when closed up in the fall.

I like to feed as late as is consistent with good results, so about Oct. 1 the colonies are looked over, and fed or united as occasion demands. I make sure that they are all strong, and that the queen appears vigorous and lively.

About Nov. 1 the hives are set on winter stands 14 inches high, to keep them out of the snow, and the winter cases are put on and packed tight with hay or straw. During the winter, if the thermometer reaches 46 in the shade, and the sun is shining, the bees come out and fly. Some of them fall in the snow and are lost, but never enough to do any harm, as they are mostly old bees.

But it is in the spring that the value of this method is most noticeable. As soon as the snow is gone, and it is certain that the bees will fly about every day, these winter cases are taken off and the hives set down on their summer stands, which are $3\frac{1}{2}$ inches high. These summer stands are leveled with a spirit-level from front to back, sidewise and diagonally, so that all foundation will hang straight, and there are not apt to be any cold corners in supers. As the hives are changed they

WINTERING OUTDOORS IN SINGLE-HIVE WINTER CASES

BY P. W. RICHARDSON

The method of outdoor wintering which I have followed for the past four winters has been so uniformly successful that I thought perhaps there might be suggestions by which others might profit. The wintering problem is not solved, nor will

are looked over and given clean bottom-boards, follower-boards, and frames of honey, if short of stores. At this time it is not unusual for some of the frames to look as if there had been water on the top-bars during the winter, but I do not regard a little water as a calamity, for brood-rearing probably begins late in January or early in February, and if the bees do not use this water for brood-rearing, where do they get it?

The hives are then wrapped in newspapers, a small chaff cushion laid on top of the sealed cover, and a telescope K cover pushed down over all. They are left in this way until settled warm weather. The entrance is usually enlarged to $\frac{3}{8}$ by the width of the hive soon after setting on the summer stands. Instead of being troubled with spring dwindling, the trouble is just the other way, for a good deal of attention is required for a time to control swarming and to prevent increase.

PLENTY OF PACKING AND A CONTRACTED ENTRANCE

As Opposed to Tarred Paper Winter Cases and a Large Entrance; Wintering in Observation Hives

BY E. C. BRITTON

I read with interest the article by Mr. Arthur C. Miller on hive protection, Feb. 1, p. 73, also the other side of the question by Mr. R. F. Holtermann, p. 74, and Mr. J. L. Byer, p. 76, and as I live 28 miles from Providence, R. I., the home of Mr. Miller, and have made a number of experiments with observatory hives having glass sides, rear and top, I wish to add a word in favor of the best possible protection for our bees.

We have from twenty to thirty hives which we winter out of doors. They are protected by boards on two sides, and by a roof which is waterproof.

We pack these hives all around to a thickness of between eight and twelve inches with pine needles, leaves, or hay, and contract the entrance to $\frac{1}{4} \times 5$ inches.

Last winter I uncovered one of them in order to see how the bees were getting along. They looked well; the glass was clear, for they had an observatory cover and feeder combined, and were lively, and their number seemed the same as when they went into winter quarters. I left off the protection, wishing to see what would happen. In a short time moisture began to gather on the glass, and great drops of water hung ready to fall on the bees and

comb. I put on a heavy black tar paper, folded so as to fit closely over the hive, and awaited the result.

On removing this cover, a few hours later, I found that the moisture was still there. I again put on the same paper cover and kept it on the rest of the season, and the colony went to pieces and was no good that year. I unpacked another hive at the same time, which I treated by the other method. As soon as the moisture appeared I covered the hive again with leaves, hay, or pine needles, which ever was handy at the time, to a depth of a foot on the sides, top, and bottom. Each time that I inspected the hive after the extra protection was given, it was in perfect condition. I have frequently examined hives in different near-by towns; and when additional protection has been necessary, and has been given, the colonies have always been benefited.

The hives (which are all observatory), from which we get the most honey are located in the tower and attic of our houses the entire year. The entrances are so arranged that the bees can have free access to the outer air at all times, but can not enter the room. In the tower there are five hives where the temperature remains at about 50 degrees the whole winter, and we get from one hundred to two hundred pounds of honey from each colony every year. We do not have to give any extra protection to these hives during the winter. In the attic we have three colonies where the temperature at times goes down to freezing.

Each hive is protected during the winter by a heavy woolen cover, tied firmly with a string. For five years the entire lot of hives of bees, both indoors and out, have wintered perfectly—no moisture, glass clear, and the bees quiet, and they have built up early and strong every spring. We get the most honey from the colonies indoors. Those outside we use for breeding.

Canton, Mass., Feb. 13.

The Lesser Wax-moth

I have some very nice honey that I have taken from my bees this season, but have discovered that there is a miniature worm or moth that has made its way to some of the boxes. I should like to have your opinion as to how it should be cared for after it is taken from the hive.

Thompsonstown, Pa. W. A. RUMBERGER.

[It is apparent from what you say that you have the lesser wax-moth in your honey. This should be fumigated with the fumes of sulphur in an enclosed room, or, perhaps better, use carbon bisulphide. This should be placed in a small dish above the supers where the honey is placed; and as it evaporates the fumes settle down through the honey and kill the pest. For particulars regarding the lesser wax-moths, see ABC and XYZ of Bee Culture, under head of Bee-moths.—ED.]

Heds of Grain from Different Fields

A Packing-case for Winter which Fits the Regular Hive-cover

Last year I used a winter case which is very inexpensive, as it does away with the usual extra cover and bottom-board. The box is six inches larger all around at the bottom edge than the hive, and tapers up to a point about a foot above the hive, where it is small enough to take the regular cover. If made any shallower it comes too close to the top edge of the hive and prevents pouring the packing around the hive. To close

the opening below I make a frame of six-inch stuff the same size inside as the outside of the hive. When ready to pack I slip the hive forward on its bottom about one inch, and then slip the frame down till it rests on the bottom at the front and back. The packing-box rests on this frame; and if the box is held in position until some of the packing is poured around the hive it will not move off its frame afterward.

If the box is made of half-inch matched lumber it will not leak; but if made of plain lumber it should be covered with tar felt.

Palermo, Ont.

H. A. SMITH.

[This arrangement here shown will be satisfactory provided a full foot of packing is used on top, as shown in the drawing; otherwise there would be too little top protection.—Ed.]

An Extension Wheelbarrow in Use in the Apiary

The illustration shows my "bee automobile," which I made myself. It is long enough to hold five hives. Mine is made of 2x2 oak, but I believe the same size of pine would be strong enough, and would be much lighter. The handles

should be wide apart, as then it handles much easier.

For a spring I use one from a lumber wagon seat. It should be a good stiff one. This is very handy in putting bees in and out of the cellar, as it carries them very easily. It is also very handy in carrying empty supers to the yard, also in returning filled supers to the shop.

Eagle Bend, Minn., May 14.

Sealed Covers Unsuccessful for Single-walled Hives During a Cold Winter

Colonies packed with sealed covers are wintering disastrously. But first of all let me tell you

how I packed them. I selected two colonies which heretofore had wintered almost perfectly with scarcely any mortality. They were exceedingly strong in bees and brood late in the fall, as I had fed them granulated-sugar syrup until late in September; and when I packed them the last week in September they had an abundance of sealed stores and plenty of young bees, and the queens (of current year's raising) were all right. I placed a super cover over the brood-chamber, and over this a full-depth hive-body filled with woolen rags, dry leaves, sawdust, and newspaper on top of all, and then the cover. Next I put several thicknesses of heavy cardboard around the hives and fastened it securely with tacks and string. I next reduced the entrance to 6 inches by $\frac{5}{8}$, and left them with my other colonies to winter over until spring. You will understand that I winter my colonies out of doors on their summer stands.

The first two weeks in January we had zero weather, and one morning 11 below, with considerable snow. When the cold had abated somewhat I took a look at my colonies in order to see how they stood the intense cold, and compared the number of dead bees in each. I raked over a quart of dead bees out of each hive one evening, and the following day just about as many. At that rate of mortality, they would soon have been entirely depopulated, so I immediately removed the super cover, and, throwing a piece of woolen cloth over the brood-frames, I put back the supers and filled them with cork chips. I then looked to see how the other colonies fared, and was surprised to see very few dead bees on the bottom-boards. By means of a hooked wire I raked, on an average, only about 30 or 40 bees from each hive, and these were all packed with absorbents over the clusters. The entrances were of the same size—6 inches by $\frac{5}{8}$.

Since replacing the sealed covers of the two colonies in question with absorbent packing there has been practically no mortality, and therefore I think that sealed covers are not a success. Theoretically it sounds very well when it is claimed that the moisture in the hive collects on the sides and runs out of the entrance in the form of water. In zero weather it does not; and since the interior of the hive is but a few degrees warmer than the outside air it must necessarily collect just outside of the cluster, and overhead especially, since this warm moist air rises as a matter of course. It can not pass through the wood, so it collects there in the form of ice and frost. This icy covering is not conducive to good wintering.

I forgot to mention that these two hives were soaking wet inside, and the dead bees I raked out were saturated with water, and partially covered with ice and frost. It is very evident that the moisture from the bees congealed as fast as it emanated, and that the cluster was surely enveloped in an icy covering. Of course the conditions this year were abnormal and we had zero temperature for about two weeks without interruption, which in this locality is a rarity. I am fully convinced that sealed covers in severe winter localities are a failure, but in milder climates they may be very satisfactory. But for the best results in outdoor wintering nothing can compare with

absorbent packing. Two years ago the mortality in wintering in this locality exceeded 75 per cent, and one beekeeper near me lost 17 out of 18 colonies; but I had nine packed with porous packing over the cluster and lost not a single colony. No more sealed covers for me.

THE IMPORTANCE OF YOUNG BEES IN THE FALL.

I have found that a colony will winter perfectly, and be in the best possible shape in the spring, if brood-raising is encouraged until late in the fall. The hives will then be stocked with young bees, vigorous and active, which are the very life and backbone of the colony. My best colony, No. 2, has even now, Oct. 21, six frames of brood in all stages, the result of feeding about a pint of sugar syrup

every other day. Spring stimulation (which I think is a grave mistake) will be unnecessary, as the bees will have an abundance of stores, and young vigorous bees to convert these stores into brood just as soon as pollen is available, which, in this locality, is about Feb. 10. Pushing a colony to its utmost by feeding, after a winter's siege, in its somewhat weakened condition, is folly, and always ends in a protracted lull in brood-rearing just as soon as the feeding is stopped, and often in a supersede of good queens at a time when every day counts.

Cincinnati, Ohio, Feb. 6.

ALBIN PLATZ.

Sixty Cents' Worth of Syrup Saved Colonies that had Produced \$15 Worth of Honey

Publishing a weekly newspaper for a living has been my occupation for several years; but during this time I have had much experience with bees. I have been associated with those who have learned much about the business, and for several years I have kept from twenty-five to fifty colonies. While my bees have paid me well for the time I have given them, they have also given me the opportunity of learning the business—that is, what I know about it. Three years ago I began to make increase, and now I am running 175 colonies in one yard, and am giving about half of my time to them during May, June, and July.

In 1911, 110 colonies yielded over 7500 pounds of bulk comb honey, which was sold at 20 cts. a pound. I live in the sourwood belt of Piedmont, North Carolina, and it is no trouble to sell this fine honey at a good price. After the honey harvest was over, which was the last of July, I turned my attention to the newspaper and paid almost no attention to the bees until the time came to prepare them for winter. They had increased until there were 160 colonies in the yard. When I examined them in October I found them so poor that it was distressing. Strong colonies—that is, strong in bees—were almost entirely out of honey. Many had less than a pound. How to feed so many, and do it at once, was a problem. I had a local factory make fifty boxes the same size as a brood-frame, and as wide as three frames. Then I removed three brood-frames from each colony and gave one of these new boxes to each colony that I expected to feed at once. With boxes ready I would pour 300 pounds of water in the extractor and mix 300 pounds of granulated sugar with the water. Just before night I poured ten pounds of this sugar syrup into the feeders, and by the next afternoon it would all be taken and stored in the combs. After giving each colony 20 pounds of syrup I removed the feeders to other colonies and thus the whole yard was fed. It was with some fear that I waited to see how the bees would come out in the spring with so small a quantity of feed; but, to my delight, when they were examined the first of March of this year I had 155 colonies in what I consider fine condition, and every one of them will make strong honey-gatherers.

This experience has proven to me that there is no reason why any one should let bees die for want of food. Less than sixty cents' worth of feed saved strong colonies, some of which had given me as much as fifteen dollars' worth of honey; and why should I let them starve when sixty cents would save them?

BEE PARALYSIS.

Three years ago I noticed two or three colonies that failed to build up strong. I observed that the bees would crawl about the hive, and that they were unable to fly. I read up on all the bee diseases, and informed myself as best I could from all the literature I had. It was very evident that there was paralysis in my yard. That season I paid but little attention to the weak colonies, and they failed to build up. In the fall, several died. Last year the trouble showed itself in as many as a dozen colonies or more. Then I got busy. I bought a pound of sulphur and dusted a tablespoonful on the combs of brood and let it fall into the cells, regardless of the statement that this would kill all the unsealed larvae. In a week I could see an improvement in conditions. Mature bees would appear to be well, and a second treatment with sulphur stopped the old bees from crawling about. But after a few days I noticed that the queen's eggs failed to mature, and that

the brood was not in solid sheets. From the observation I made, I concluded that there was also trouble with the queen. Then I placed a young queen in every colony where the disease appeared. After the sulphur treatment and requeening, these sick colonies built up, and many of them made as much as a hundred pounds of surplus honey during July, and without any help from other colonies. And the beauty of it is, that this spring these same colonies that were in such bad condition last season are permanently cured, and among the best I have in the yard. This spring the trouble has shown itself in a few other colonies, and every one has yielded to this treatment.

In a few cases the colonies recovered slowly, and I gave two or three frames of hatching brood from a strong colony, and thus strengthened the working force, and all went well. My experience with as many as twenty colonies of sick bees has been that a tablespoonful of sulphur dusted over the combs, and a new queen, puts the colony "on its feet" again.

Mount Airy, N. C., June 21. J. E. JOHNSON.

A Cleated Thin Board Slid into the Entrance to Act as a Storm-door

While looking over back numbers of GLEANINGS I came across the description of a double hive-bottom for winter protection, by Joseph F. Rose, Jan. 15, 1908. I have a similar but much simpler device which can be applied to any hive having a drop bottom-board, without necessitating any change thereof. The advantages claimed for the double bottom-board were: Prevention of cold drafts; bees flying out on sunshiny but cold days; stoppage of

the entrance by dead bees or ice, and spring robbing; to which I would add, promotion of late and early brood-rearing. All these advantages go with what I designate a winter entrance-board, which is simply a thin wide board suitably cleated to preserve a bee-space above, and an entrance underneath when pushed into the usual $\frac{3}{8}$ -inch entrance opening between the bottom-board and hive-body.

I make these boards of red-cedar shingles (which come very wide), planing them to $\frac{1}{8}$ inch by hand. The top cleat across the front is $\frac{1}{4} \times \frac{1}{2}$ inch; the end cleats are $\frac{3}{8} \times \frac{1}{2}$ inch, all fastened with thin wire nails clinched. I use two different sizes, one 4 inches and the other 8 inches wide. The smaller one is put in when the nights begin to be frosty, and is replaced by the 8 when warm days are scarce. The 8 is left in place until the bees are seen fanning in the middle of a warm day in spring; then the 4 is substituted, and left until settled warm weather. These boards being put in place late in the season are not glued fast, and may be withdrawn at any time to rake out dead bees.

I am using this season two inches between the bottom-board and hive-body in conjunction with the winter entrance-board, to secure space under the frame for clustering early in the winter; also ample space for dead bees, better ventilation, and as a further preventive of excursions in cold weather. I find these rims useful during the season when introducing queens from mailing cages, for top feeding, and wherever space is wanted above or below for experimental purposes. Each rim has a spur (the point of a wire nail) set exactly in the middle of each long side, so that, when placed correctly and pressed down on the

bottom-board body, or super, it does not slip about. The rim is placed with the spurs always on the under side.

Hoboken, N. J. C. D. CHENEY.

[At one time we thought there might be some advantage in making an obstructed entrance of some sort. The various devices that we tried to prevent a complete wind sweep did more harm than good—bees were confined, and proper ventilation was not secured. Colonies with obstructed entrances were either weak or died outright, while those with free entrances came out in good condition.—Ed.]

Rock Candy a Failure for Feeding

I fed my bees rock candy last winter. One cake of candy was too hard. This the bees could not eat at all, so they starved. The other cake was underdone to the extent that drops of syrup would form on the under side of the cake after standing a while. This the bees ate; and if they had had another cake when that was gone I could have saved them. The colonies I lost cost me \$8.00; but I would not take that much money for what I learned.

Next winter I will make a dough of pure honey and sugar, then I will make shallow wooden boxes of $\frac{3}{4}$ stuff—2 inches deep and 12 square. I will put on the stove a wash-boiler containing a bucket of water and a 15-cent cake of paraffine. Just as soon as the paraffine is melted I will dip the wooden trays in the mixture a few times until they are coated inside and out. The trays should then be filled and set on top of the brood-frames. After bridging over the trays they should be covered with some kind of thick paper, and then put in the packing—the more the better. Such colonies will winter sure. I would not advise any one to try to winter bees on rock candy; for even if they eat the candy there is likely to be some of it wasted—by the small particles falling down between the frames.

Jonesboro, Ind. C. A. NEAL.

[If you can feed syrup in October so that the bees will store it in the combs we are quite sure you will find it not only less work, but more satisfactory in every way. We would advise the use of candy only when the stores have run short during cold weather when syrup can not be had.—Ed.]

A Plea for Cellar Wintering

A great deal has been said of late in favor of outdoor wintering of bees, and we rather think the editor favors that method for us Northern beekeepers. Of course it is taken for granted that outdoor wintering is all right for warmer climates. My own experience is that here in Pennsylvania cellar wintering is much to be preferred—first, because it requires less labor and fewer stores; and, secondly, it is surer to bring the bees safely through our long rigorous winters. For the past eight years we have wintered our bees in our house cellar with uniform success, never losing a colony unless it lacked stores or bees when put in in the fall.

Last winter was the coldest for 40 years in this locality, and the temperature in this cellar was almost to the freezing-point for days; yet we lost not a colony except one that was queenless for a long time in the fall and contained only old bees.

Our cellar is 22x28 feet, built of small flag or field stones and mortar, all except 18 inches on top, which is laid with rockface split stones. A drain is under the entire wall leading out to a near-by ravine. The adjacent soil is clay; but the cellar is always quite dry, but not too much so for a good vegetable-cellar.

A summer, or beam, passes through the cellar lengthwise, supported by two heavy posts resting on stone pillars. Between these posts our bees are stacked without any preparation except provision for sufficient stores. We like to have the hives in the center of the room, as there is less mold there, owing to the better circulation of air. As soon as the buckwheat flow is over, the supers are removed, as that is the last honey-yielding plant that gives any surplus. The covers are put down on the brood-chambers, and the bottoms are reversed from deep to shallow entrances. This precaution is for the purpose of keeping out mice.

The deep side of the bottom-boards would be better than shallow in the cellar if it were not for mice getting in and chewing up combs.

As soon as settled cold weather comes on, the colonies are carried into the cellar and stacked, and that is about all there is to it. There is no fussing with packing and paper covers, etc. We simply carry them in and carry them out again in the spring. No quilt or mat should be used on top of the frames while the bees are in the cellar. The bee-space between the cover and top-bars should be entirely free for the easy passage of bees over the tops of the frames. In fact, we long ago discarded all mat or cloth covers on brood-chambers. They are an intolerable nuisance. We use oilcloth covers on top of section supers only.

All around this cellar are bins usually filled with potatoes, apples, and other vegetables; yet the bees have always wintered successfully.

If a warm day comes in February or March we carry them out for a fly, remove the dead bees from the bottom-boards, and return them until settled warm weather.

Summerville, Pa.

W. P. KEEFER.

[Where there is a perfect cellar, no plan of wintering is so ideal; but if the conditions in the cellar are not right, or in locations where the winters are open with comparatively short stretches of cold weather, the outdoor plan is the better. There is a great difference in cellars. In some, where conditions seemed to be all right, we have lost a good many colonies.—Ed.]

Bees Wintered Better Packed in Paper than in Wooden Cases

I read in the Feb. 1st issue with much interest the discussion between J. L. Byer and others in regard to winter cases. Especially was my attention called to Mr. Byer's opinion of black paper cases for protection, because at the time of the discussion part of my bees were in paper cases.

I can't number my colonies by the hundred, but I keep bees in the back of a city lot for relaxation, pleasure, and profit. I have my hives set in pairs about a foot apart and three feet between the pairs. Heretofore I have used large knock down wooden cases containing one pair of hives, allowing two inches of chaff under the hives and 10 inches on all sides, and 12 inches on top. I have had splendid success wintering in these cases; but last fall I had eight hives more than I had cases for. These I packed in paper. First I took old newspapers, covered the cases all over, about 25 sheets thick, then covered this with table oilcloth, and on top of this I put black roofing paper.

I had no trouble with bees flying out when too cold, neither did they freeze inside, and sweat, as some report. But they wintered better and came out more vigorous than the ones in large wooden cases; and the two that I lost out of 22 were in wooden cases.

Urbana, O.

O. J. JONES.

Holtermann's entrance-contractor, mentioned on page 75, Feb. 1.

Three Essentials for Wintering Outdoors

Last season the bees all over this part of the country got practically no nectar after June 20. In order to stand some show of wintering them I fed each colony about 25 lbs. of granulated sugar, commencing with a little stimulating feed for the purpose of keeping the queen laying as long as possible; and in October I gave them about all they would take from the Alexander feeder in one hour; and by November 24 I had them in fairly good condition, with plenty of young bees and good pure sugar syrup.

I then put them in a row several inches above the ground, packed leaves under between and on top of them until they were completely buried. Then I made a frame around them, well covered, and contracted the entrances to about $\frac{3}{4} \times 4$, and bade them goodbye until April 2, when I unpacked them, found one dead, seven fairly strong, four rather weak, and one queenless.

The fact that I lost just two out of 13 colonies, and in a winter when there was a lot of zero weather at that, makes me feel like promising that I will not lose that many any more. There are three things essential to perfect wintering of bees on the summer stands—namely, a young, vigorous queen; plenty of good food, and a good packing of leaves.

Indianapolis, Ind.

J. F. KIGHT.

Cellar vs. Outside Wintering

What are your reasons, Mr. Editor, for saying you know that it takes much less skill and time to winter outside? In this locality it is quite the reverse, as it requires an expert to prepare properly a lot of bees for successful outside wintering; and a lot of time and work, aside from a large expense for outside cases. But anybody can carry a swarm of bees into the cellar, remove the cover and oilcloth, and spread a piece of burlap over the top of the hive. The bees, too, will winter just as well as those outdoors, if not better, and on about half the amount of stores. I am 58 years of age. This fall I put 131 colonies in the cellar alone in four hours. I am of the opinion that it would require a week to prepare them properly for outside wintering.

Union Center, Wis.

ELIAS FOX.

[You undoubtedly have a cellar that is ideal. If one has but little experience we think he would have better success in wintering out of doors than if he attempted to create ideal conditions in a cellar where the ventilation or temperature is not right. Perhaps we did not properly explain our former statement to which you refer.—ED.]

An Empty Super Placed Over the Brood-chamber for Packing Material

I have a way of packing bees for winter that I think is worth telling. I place an empty super over the brood-chamber, and in it put three or more section-holders spaced several inches apart. I then spread burlap sack, or any other cloth, over the bottom of the super inside, and pack dry autumn leaves until it is filled. This plan keeps the bees warm, yet allows ventilation through the leaves. At the same time, the bees have room to pass over the top-bars from one comb to another. We use no packing around the sides of the brood-chamber in this vicinity.

Arkansas City, Kansas.

W. L. POWELL.

No Loss Last Winter

My bees have always wintered on their summer stands. Some hives are packed in chaff and some in ground cork. The stores are mostly goldenrod and aster. Last winter was a record one for cold in this locality, but my bees wintered better than in any previous season for twenty-six years. There were no losses, and less than six quarts of dead bees and sweepings from 35 colonies.

Bowdoin, Me., May 7.

W. L. MALOON.

Inverted Butter-plate Makes a Good Clustering-place

As my plan of packing bees for winter, given in GLEANINGS, p. 664, Nov. 1, in which I advised placing an inverted wooden butter-dish, holding about a quart, over the frames, as a clustering-

place for the bees in cold weather, was criticised by some beekeepers, I will now report that, out of 78 colonies so packed, 75 came through our unusually long and severe winter in first-class condition, and the three that perished were found to be short in stores—pure neglect on my part. I have never before had stronger colonies at this season of the year.

ISAAC F. TILLINGHAST.

Factoryville, Pa., April 25.

Wintering Bees in the Cellar

I set my hives faced to the wall of the cellar, give full-sized entrances, and turn the covers bottom side up; detach the cloth cover from the frames near the back part of hive in order to give good ventilation, and never have any loss, with the exception of a few from dysentery one winter. I attributed this to poor quality of stores or lack of stores.

Madison, Me., Feb. 28.

W. G. SAWYER.

Cheap Concrete Blocks for Hive Foundations

For making hive foundations of concrete I use empty quart cans, such as old tomato-cans, etc., for forms. I use one quart of cement, two parts of clean sand, and five parts of gravel. When all are thoroughly mixed dry I add water while stirring constantly until it is quite soft. I fill the cans partly full of the mixture, and then put in any pieces of rocks that will go into the can, and pour in more concrete until the can is level full. After shaking them so that all air bubbles come to the top I set them in a level place for a day and a night; then take four to each hive, turn them bottom side up for the hive to rest on. When the tin rusts off the round cylinder of concrete is left.

Fremont, Mo.

MRS. ALMEDA ELLIS.

[It is very important to mix thoroughly the concrete material dry, then wet it, to the consistency desired. Your scheme of old fruit-cans to make the forms is excellent.—ED.]

Is there any Advantage in Placing Supers Below rather than on Top of the Brood-chamber?

Can bees be induced more readily to work in the super by placing the super below the brood-chamber for a short time? Is any bad effect brought about by such method? When an after-swarm is led off by a virgin queen, does the queen mate while the swarm is in the air, or will she, after the swarm is hived, leave her new home to make her wedding-flight?

Deerwood, Minn., July 27. WALTER G. WETZEL.

[There is no advantage in placing a super below the brood-chamber—in fact, rather a disadvantage. It should be placed on top of the hive, where it is the warmest, because bees, in order to do good work, should have the temperature right for comb-building. The lower part of the hive, or next the entrance, is comparatively cool, and we doubt if comb-building could progress as it should, except in extremely hot weather. Putting a super beneath the hive might have a tendency to check swarming; but we believe that is all it would accomplish.

A virgin queen, when she goes out with an after-swarm, does not meet the drone unless the bees follow her on her mating trip, which they will do sometimes. Ordinarily the swarm seeks its new quarters; and after they are comfortably settled, the virgin queen goes out on her mating-trip.—ED.]

The Difference Between Golden and Five-banded Bees

What is the difference between golden bees and the five-banded Italians? What is the difference in the color? Do you think there are differences in the working qualities? Do you think the golden bees would suit where I live?

Meadow Creek, W. Va. ALEX. BENNETT.

[The golden Italian refers to extra-yellow bees, without reference to any number of yellow bands. The five-banded Italians refer to bees that have five yellow bands, and such are supposed to be extra yellow. Our own preference is, however, for the leather-colored Italians, because in our experience the extra-yellow bees are short-lived and inclined to be cross.—ED.]

Our Homes

A. I. ROOT

While he yet talked to the people, behold his mother and his brethren stood without, desiring to speak with him. Then one said unto him, Behold thy mother and thy brethren stand without, desiring to speak with thee. But he answered and said unto him that told him, Who is my mother! and who are my brethren? And he stretched forth his hand toward his disciples, and said, Behold my mother and my brethren! For whosoever shall do the will of my Father which is in heaven, the same is my brother, and sister, and mother.—MATT. 12:46-50.

Many times while dictating these Home papers I have earnestly prayed for wisdom and guidance from above. Especially this morning I feel like uttering a prayer something like this: "O Lord, help me to comprehend the *full* meaning of the beautiful text that stands at the head of this Home paper. Clothe me with thy Holy Spirit that I may make known to the multitudes who are following me the great truth and the much-needed truth brought forth in the words of our Savior when he said, 'Behold my mother and my brethren.'" It occurs that, in years gone by, I have heard adverse criticisms of this very passage. It probably came from the same skeptics who were trying to find fault with some of the words and doings of our Lord and Master. If I remember correctly, they said he had become so excited and set up by the wonderful miracles he was performing that he refused even to notice the mother who had nursed him and the brothers and sisters who had been his companions through childhood. It is only within about 24 hours that the full significance of this wonderful passage has been revealed to me—or perhaps I had better say, partially revealed; for all that is included in those five verses will, perhaps, never be fully explored while the world stands. Just now the world seems to expect that a man shall not only respect and reverence his father and mother, no matter *what* happens, but he shall remember the ties of brotherhood and sisterhood and relationship. If one of the family gets to be quite wealthy, public opinion, and, we may say, good common sense, say that he should look after his poor relations, and at least give them a helping hand. This is all right and proper. But let us push it a little further. Suppose some man who is high up in the world, and has authority—one, say, who has been given some high position in the State or in the general government of the United States; and suppose this person should begin right away to put his relatives into important offices, and give them big salaries. You may smile at this illustration when you remember how many times this has been done and is being done. Suppose this same man who

is paid a handsome salary by the government to protect the interests of the people begins to manipulate politics and finance so as to "feather his own nest," or, if you choose, the nests of his particular friends and relatives. As you take the above into consideration I should not wonder if you would smile again. Let us now go a little further still.

Suppose the policemen of our great cities, and perhaps I might include some small cities also, who are employed to protect the public—the women and children—those who are unaccustomed to city ways and customs—the ignorant and untutored. This big policeman is supposed to be a *father* to all these unfortunates. He is appointed to see that every woman and child has a chance to live and have a "square deal" all around. Suppose a saloon-keeper begins to cultivate the acquaintance of this policeman, or, may be, the saloon-keeper who lives neighbor to him is on friendly terms. Suppose this policeman should hesitate to do his duty because of old acquaintance, or because the offender is an old acquaintance, or may be a relative. Let us now push the matter still further. Suppose a saloon-keeper agrees to give his friend the policeman five dollars a month, or may be, where he is doing a big business, five dollars a week, providing said policeman will look the other way when trouble happens in his saloon, or use his influence generally to protect him from arrest. Let me mention an instance of recent occurrence—or, instead of mentioning the incident, suppose I mention a few names: Lorimer; Judge Archbald; Judge Hanford, of Seattle; Police Lieut. Becker, of New York, and Rosenthal, who was recently murdered by the alleged connivance of the said Becker*, and Stephenson and Holstlaw. I presume I need not go any further. The trouble is these judges, policemen, governors, and (I wish to say it with reverence

*I might mention also from our own State of Ohio, Senators Dingle, Andrews, and Huffman. While going over the above names, that expression in one of our former Home papers comes vividly to my mind: "*4700 dirty dollars*"—dollars that he did not need, and, in fact, had no use for after he got them." What an awful contrast between this spirit and that of the Master when he said, "These are my mother and my brethren"! There is no mention, I believe, in the Bible where Jesus ever had a dollar. In fact, he owned nothing. He once said, "The foxes have holes, and the birds of the air have nests; but the Son of man hath not where to lay his head." I have been told there is good evidence that the clothing he wore was supplied by thoughtful good women; and yet he in his poverty healed more pain and conferred more happiness on humanity at large than any mere mortal who ever lived. "He pleased not himself."

and respect), presidents of the United States, were biased by selfishness in using their influence for the benefit of the people. Instead of loving humanity, high and low, rich and poor, equally and alike, they love their friends who have helped them to get important offices, etc. Now, I am not expecting too much of humanity—at least I do not believe I am; for I suppose there has never a man lived, and perhaps never will live, who could say as Jesus did, as he stretched his hand out toward the multitude, "Behold my mother and my brethren." What he meant to convey was this: Every child of humanity on this whole broad earth is just as near and dear to me as my own mother, my brothers, and my sisters. Who is there living who can say as much? What would it be worth to our nation if we could have just a *few* such men in office? As I try to comprehend the great truth here with my feeble human intellect, my little prayer wells up, "Lord, help." Some of you may say, "Mr. Root, do you practice what you are preaching? Do you love the great wide world as you love your wife, the memory of your good mother, your boys and girls, and sons-in-law, daughters-in-law, and grandchildren?"

As I contemplate it this minute, that little prayer rings out again with additional emphasis, "Lord, help." At such times as this, when I consider my own frailty, I thank God I can say, as poor Peter did, "Lord, thou knowest that I love thee;" and I can add (thank God), "Lord, thou knowest that I am hungering and thirsting after righteousness every day of my life." Perhaps it comes by fits and starts; but I believe it is coming oftener and stronger as I pass the mark of threescore years and ten. You perhaps have recognized that these Home papers are taking a wider scope than they did years ago. Not only are the common people reading my pleadings for righteousness and fairness, but at least one or two millionaires who got started in beekeeping are giving me encouraging words and telling me to go on.

We are told, "Thou shalt love thy neighbor as thyself." And if you ask who is your neighbor I am glad to point you to that beautiful parable that answers that very question. If I understand it correctly, our neighbor is any one who happens to be in trouble, and who is needing help. He may be white or black, rich or poor, or he may live on the other side of the earth.*

*Right in line with the above I might mention that the world is just now getting stirred in regard to the cruelty exercised toward the natives in Peru, who are gathering rubber to make our automobile

He is our neighbor still; and if he has fallen among thieves and is wounded, robbed, and "ready to die," if we belong to the Lord Jesus Christ we can not escape the responsibility resting on us. That man, though he be far away, is a part of humanity; and when Jesus said, "Behold my mother and my brethren," he meant it to include humanity throughout this whole wide world; and my impression is just now that the highest enjoyment and the greatest happiness one is capable of is along the line of our text and its teaching—that they are not only neighbors but brothers and sisters of the Lord Jesus Christ.

To illustrate the *difficulty* of climbing above human temptation, let me mention one or two instances. Years ago there was a shortage of coal here. It could not be had for love nor money. It was then almost *impossible* to keep our machinery going by buying expensive wood. We were on the eve of shutting down for want of fuel. A carload of coal stood on the track close by our boiler-room. The railroad company needed it to run their engines, and would not sell it at any price. I think I prayed over the matter, and finally our station agent came over and said something like this:

"Mr. Root, we appreciate what you have done to keep our Medina people busy during the cold winter with your factory and various offices. While that car of coal is not for sale, we have looked the matter over and decided to let you have it in order to keep you going until some more can be had."

You can, perhaps, imagine (or at least partly) how grateful I felt toward him. Now listen. With a sly twinkle in his eye he said:

"Mr. Root, would you be willing to put your name at the head of a paper recom-

tires. See the following, clipped from the Chicago *Advance* for Aug. 8, they copying it from the *British Weekly*:

"At the very time when the words 'Great rubber boom' were displayed on London posters to tempt greedy investors, the poor Indians of the Peruvian forests were dying in agony. The full responsibility for these crimes must be placed on the government of Peru. By failure to punish the evildoers individually and collectively, Peru will forfeit the right to exist as an independent republic."

I wish to call your attention to the closing sentence—who is to bring this about? If I understand it, the responsibility rests on the civilized and Christianized nations of the earth—the United States standing, if I am correct, in the forefront. Is not the time coming when the spirit of the master shall leaven the whole lump of humanity, so that no more slavery, barbaric cruelty, nor suffering from starvation and hunger, shall exist *anywhere* on the face of this *whole wide earth*? The sentiment of our text will bring it about, and it is the only thing in this whole wide universe that will bring it to pass.

mending my father for postmaster? You get almost as much mail as all the rest of the town together. You are well acquainted with my father. Don't you think he would be as good a man for the position as we have in sight?"

There you have it, friends. What could I do under the circumstances? It happened in this case that his father *was* a very good man, and had been postmaster before, so he was well qualified for the duties. But suppose he had been a man wholly unqualified for the place—then what? None of us, especially those of us who profess to be Christians, like to be uncivil or unaccommodating. I suppose we often assent to some things that we can not exactly approve of, because it would be unseemly or uncivil to refuse.

In the incident quoted in regard to the Savior, we are not told that he stopped his work even to talk with his mother and family. In another place we are told the family remonstrated with him, and told him he was wearing himself out. They wanted him to take a little rest. How could he rest when he saw the suffering, the injustice, and the lack of a Christian spirit? Let me give you another illustration. If the incident did not exactly happen, something very much like it *has* happened or might easily happen.

A boy and girl were brought up together. The boy was the older of the two. While his sister listened to her mother's teachings, and became a pure sensible girl of lovely character, the boy fell into bad ways. Tobacco and strong drink carried him down and down until he got into the maelstrom of worse evil than either of the above. His sister went to a large city alone to meet a friend. She had an idea that her brother was in the same city; but as it had been a long time since he had written home she did not know where to find him. By some mistake her friend did not meet her at the station. She told a lady who happened to be there of her perplexity and trouble. This lady (?) said that, very fortunately, she lived quite near her friend, and would take her there in her own carriage. This woman whom I have called a lady was an agent of the white-slave traffic; and in a few hours this girl found herself in a strange place under lock and key. Along in the night the door was unlocked. This same woman ushered in a stranger, saying, "There is your girl, and I think you will find her all I represented her to be."

The brother and sister faced each other appalled, and I think the outcome was that they knelt down together and thanked God

that it was *her own brother* who had paid quite a sum of money in order that he might meet the sister of *somebody else* instead of his own. Do you see the application, dear friends? Had this depraved and vile victim of evil associates loved *all* the nice-looking girls in the world, just as he loved and revered and respected *his own sister*, the daughter of the same sainted mother, how could he have consented to be a party to such work?

If all humanity or just a sprinkling of humanity could for a part of the time stand where the Savior stood when he said, "Behold my mother and my brethren," what sort of world would this be? What a difference it makes when we unexpectedly run into relatives or relationship!

At some gathering of a lot of men, I have forgotten where, some one stood up and told a story that reflected on all woman-kind. There was one Christian man in the lot who could not stand it. When the laugh and jeers had subsided he got up and said something like this:

"We presume the gentleman who told this story had in mind his own wife, mother, and sisters."

This little speech made a row. The one who told the story was ready to knock down the man who had insulted him. It seemed as if the great truth in the lesson before us could scarcely gain a foothold in his sin-stained heart and mind. May God help *us*, we who call ourselves *men*—may he help us every day of our lives to look on all womankind, especially in this present day, when they fill our busy streets attired in garbs that would rival the butterflies of summer—let me say it again, may God help us, who call ourselves men, to look on every woman, and to *think* of every woman in our inmost souls, as we would that other men should look on and think of *our* wives and mothers and daughters.

Just before dictating this Home paper a letter was put into my hand. There is one passage in this letter that shines out like a bright star. The writer says, "The greatest asset that ever comes into a man's life is the Lord Jesus Christ." Can't you—a great lot of you—say amen to it, and pass it along? By the way, I think I will give the whole letter, or a great part of it, for it is a bright and shining one, to a great lot of others as well as to your old friend, who is very likely, *at this very moment*, as your eye alights on these pages, praying that he may look over humanity throughout the whole wide world, and say with the dear Savior, "Behold my mother and my brethren."

My Dear Brother Root:—I have been thinking of you of late. In regard to the excellent work you are performing for our Lord, I must admit that I have been a poor Christian. I have been a heavy smoker and chewer, and a light drinker. I well remember being intoxicated once in my life. About three years ago I happened to pick up one of your GLEANINGS at a friend's house, and in looking over its pages I noticed your excellent work in bringing souls to God. Your notes at once took such a hold on my heart that I began to pray to our Lord, asking him to give me grace, and help me to abstain from drink and tobacco. At once I began to realize that I had heretofore been taking the "wide path." Thanks to our heavenly Father that I did visit this friend, for I have now no desire for drink or tobacco; have not touched it in three years, and, with the help of our Lord, I never shall. When I told my better half of my intentions she thought I would be back to my old ways in a few days; but now she is delighted with my reforming.

We have five children—from thirteen to twenty-five—all in fine health, thank God.

When I began this "reforming" I thought of our Saviour, who fasted in the wilderness forty days and nights. In other words, he was preparing for the crucifixion, not because of notoriety—nay, it was a spontaneous affair from start to finish. Yes,

it was the demonstration of genuine, Christlike love, that all the world might have life, and have it "more abundantly." No man has ever championed the rights of the people with such love and sincerity as did our Lord. Likewise, no one has ever had such a burden to bear; and most certainly the world has never had such a conqueror, though as yet I fancy that we are failing to practice the plain and simple teachings of our Lord. Our false pride is robbing us of our daily happiness. The sooner we can see each other as members of the human family, entitled to all the blessings of our heavenly Father, the sooner shall we have heaven on earth. Jesus Christ is the greatest asset that a man can have. This I have experienced, thank God.

How true the saying, for Jesus has said "Without me ye can do nothing!" Behold, the light of heaven is still shining, for "God is love."

Yes, brother Root, I feel like a new man, and am so happy because I know I am with God since I have learned to love my Saviour.

Now, brother Root, I feel that God inspired you to perform this noble and holy work, to bring us poor sinners to him. God bless you, brother Root. I hope to see you some day in the near future, hoping that our Lord will spare you many more years.

A. SANDERS.

Orange, N. J.

High-pressure Gardening

TRANSPLANTING AND CULTIVATION OF ALFALFA.

With the present outlook in regard to the importance of alfalfa on the farm, and to poultrykeepers in general, it looks as if every man, woman, and child who has even a little bit of ground should learn to grow alfalfa; and we might also say the same thing in regard to its near cousin, sweet clover. Alfalfa is now universally acknowledged to be one of the most important legumes, if not the *most*, for all kinds of farm stock, and great quantities of alfalfa meal are bought and used by poultrymen; and since it is being daily demonstrated that alfalfa can be profitably grown almost everywhere in the United States, and, for that matter, all over the world, it behooves us, each and all, to find out by experiment just how to grow it in our own locality. The *Dakota Farmer* has given us a recent article from the man who has been testing different varieties of alfalfa. I think the Department of Agriculture sends him out to collect seed of different varieties. We have space to give only the following extracts from the article:

We have been giving demonstrations of my new method of handling alfalfa by transplanting the one-year roots instead of sowing seed. May 2, 1912, we had a demonstration at the J. W. Parmley farm, Ipswich, South Dakota, and set plants at the rate of 100 per minute or 6000 per hour.

Demonstrations of this machine planting were first made on April 23 at Brookings, then at Redfield, Big Stone, Eureka, McIntosh, Lemmon, and Onida. I claim no originality for the method except that this is the first time where a machine has been used for transplanting alfalfa. In other words, I have combined an old Oriental method with an American machine. I took one of the standard transplanting machines, the Bemis, used

for tobacco, cabbage, tomatoes, cauliflower, sweet potatoes, and many other plants, using a nine-inch shoe slightly widened at the back to allow more space for the alfalfa roots. This was done by a local blacksmith. Personally I have used the method since the spring of 1907, with the new alfalfas I brought from Russia and Siberia. Being trained as a horticulturist, I knew it would be the best way to make the most out of a small quantity of seed. Some of the reasons which occur to me at this time are:

1. The present method of using twenty pounds of seed per acre means fully one hundred seeds per square foot. Instead of that, every plant should have several square feet—the exact number no one knows as yet. The distance probably depends on the soil, elevation, and moisture conditions.

2. Alfalfa plants should be given full opportunity for maximum development. When set in the garden two by four feet, we get plants with over 500 shoots to the crown, and bearing as high as three ounces of seed per plant the third year, on plants transplanted the first year from seed. This means 1029 pounds of seeds per acre. The variety was the one secured in Russia, which I have named Cossack. From present prospects they will yield much more the present season.

3. The parasite vine known as "dodder" is a very serious menace to the alfalfa industry in a great many States in the West. It is extremely difficult to separate it; and when in the field it will soon ruin it. In Europe such fields are put out of commission by the government. But plants in hills could easily be kept clean.

4. The present methods of overcrowding the plants give an inadequate supply of moisture. Such plants are much dwarfed and can not form the long tap-root necessary to endure drouth.

5. If the plants are raised in thoroughly inoculated soil, every plant will be perfectly inoculated before setting it. This is of itself a great advantage. A farmer can see the nitrogen-gathering bacteria nodules with his own eyes.

6. The present methods of diskings are extremely injurious. Such plants quickly become black-hearted, and the germs in the soil which produce decay soon obtain entrance. This crown-rot causes the plants to die early. I am fully aware that this is contrary to the present teachings of all the experiment stations, farm papers, and farmers' institute lectures; but I am satisfied that a careful examination of plants will show the truth of this statement. Alfalfa spike-toothed "renovators" would no doubt cause similar injuries. Alfalfa fields in the Orient are shown four hundred years old; but the Orientals do not mutilate their plants as we do. The heart

of an alfalfa plant should be held as sacred as the heart of an oak tree.

7. Alfalfa plants in this spring's demonstrations were set two feet apart in the rows, with rows three feet eight inches apart, so that the common corn-cultivator can be used. My opinion is that they should be given cultivation one way just like fodder corn. But perhaps check-row machines will be devised to make feasible mechanization in early spring and after each cutting.

8. Alfalfa is a very poor fighter the first year, as the main strength goes below ground, hence it is often choked out by weeds which make more top than root. But by setting out a goodsized alfalfa plant, often as big as your middle finger, they can hold their own better against the weeds.

9. Over 1200 farmers are co-operating with me in testing these new alfalfas. Some report obtaining 7000 to 8000 seeds per plant the first year, and one North Dakota farmer reports raising one pound of seed in 1911 from eight plants set in the spring of 1910, which means 25,000 seeds per plant. The variety was the Cossack.

10. The plants should be raised the first year in good garden soil that is well inoculated. They may be transplanted in the autumn of the first year; but the bulk of them should be kept in outdoor cellars, such as are used for storing potatoes or trees, or they may be heeled in close together in furrows made with a plow. In 1910, at this station, on a piece of good garden soil 60 by 165 feet, 50,000 Orenburg alfalfa plants were raised, which is about 220,000 plants per acre. Probably much more could be done if no cut-worms, etc., appear. These were raised in drills, much like carrots and beets.

11. The plants are dug with a tree-digger, cutting under the roots, which is better than the plow, as the plants are easier to find. This implement is much used by nurserymen. Some of the cheapest cost as low as twenty dollars, and can be made by a good blacksmith. The roots are shortened by using a meat-cleaver on a block of wood, being careful to avoid bending the roots. It is better to shorten the roots than to bend them, so that the new roots, when they form, will go straight down. When set, the roots are covered entirely with earth, thus preventing evaporation until established.

12. I believe that the method will very greatly hasten the spread of the hardy Russian and Siberian alfalfas throughout the prairie Northwest.

On my alfalfa-planting tour I found in almost every place, men from Wisconsin and other States who had worked on these tobacco-transplanters, and knew that they are a commercial success in transplanting almost any thing in the plant line. We found that one barrel of water is sufficient for 5000 plants.—Prof. N. E. Hanson, *South Dakota State College of Agriculture and Mechanic Arts, Brookings, South Dakota.*

Please notice in the above the amount of seeds wasted when sown broadcast or even drilled in. This wasteful broadcasting would use a thousand seeds where only one is needed. Suppose a farmer should undertake to raise a crop of corn by such a wasteful method; and from what experience I have had with both alfalfa and sweet clover that came up in the garden, and thus secured the benefits of cultivation, I honestly believe it will pay to grow your plants and set them out and cultivate the alfalfa one way, and possibly both ways, just as we do with corn. The additional fact that you get rid of dodder and all other pernicious seeds is a matter well worth considering.

Now, shall we not, every one of us, get to work and grow some alfalfa in our garden in order to learn how? When you have grown a square rod successfully you

are ready to grow an acre. Professor Thorne, of our Ohio Agricultural Experiment Station, recently told me we could get inoculated soil wherever we can find a rank growth of sweet clover.

Let me add, in closing, that good wholesome bread is now being made in California from alfalfa meal; and I suppose this meal is chiefly of alfalfa leaves. Now is the time to sow the seed, just after you dig your early potatoes, or where seeds have been removed from your garden; but whatever you do, give your soil a good liming. An excess of lime can not do any harm, and lime will always be a benefit, more or less, with sweet clover.

"WHO IS MY NEIGHBOR?"

In connection with the topic discussed in *Our Homes* in this issue is another matter. While discussing natural-hen incubators, page 391, June 15, I neglected to mention that the vender of the single sheet of paper, for which he charges \$1.00, wrote me a very nice and kind letter, telling me how much he appreciated this department of our journal, hoping I would see my way clear to use my widespread influence in helping him introduce his discovery, etc. Now, I confess it is pretty hard to show up a man as a fraud when he writes so kindly; but where does my duty lie? Shall I favor this one individual who writes a kind letter, or should I protect the honest, hard-working people scattered all over our land? *Who* is my neighbor? I think I can almost hear the voices of thousands, telling me to go on exposing frauds. Well, just now I stand face to face with another thing along this very line. A good friend of GLEANINGS sends me a clipping from one of the poultry journals. It reads:

Blanchard's new system of corn raising increases your yield 10 to 25 bushels per acre.

Furthermore he says:

You can have confidential use of this information for \$1.00; and as long as my supply lasts I will mail you one ear of corn, perfectly tipped, to show what I have accomplished. You can use this for seed. Book and corn come together. The biggest dollar's worth on earth.

W. J. BLANCHARD, Abington, Mass.

After I sent the dollar, another pleasant letter came, saying that the writer, years ago, took our journal, has the A B C book, etc. He says he very much enjoyed reading my sermons, etc. With the letter he sent four beautiful ears of corn, the kernels growing clear up over the tip. Now, inasmuch as friend Blanchard has treated me very handsomely, *perhaps* I ought not to complain, or at least not complain very much. The four ears of corn, on which he paid 21 cents postage, are very likely

worth a dollar for seed; but as a rule he sends only one ear of corn, and, as I take it, not always that.

What about the book on corn-raising? It contains just 12 pages. Nearly one-fourth of the book is devoted to advertising his strain of White Leghorn chickens. The rest of the book, as I understand it, is about as follows:

Most corn-growers are in the habit, when shelling corn for seed, of discarding the small kernels on the tip and the bad-shaped ones on the butt of the ear; and I think our experiment stations have recommended this more or less. I can not now recall just what Professor Holden says about it; but I think that he also rejects these small ill-shaped kernels; and it now occurs to me that I have somewhere seen it stated that these kernels on the tip of the ear should *not* be thrown out when planting, for the reason that, if you plant these as well as

the others, you will be more likely to get a strain of corn with the grains all around the tip as thick as they can stand. Well, Blanchard's "new system" consists of saving and planting these tip and butt kernels, and *not* throwing them away; and this invention, so far as I can make out, is simply going contrary to what the experiment stations have advised. I am unable to find any thing in the entire book worthy of mention (aside from the above) that will enable the farmer to increase his yield from ten to twenty-five bushels per acre, as advertised. Once more, who is my neighbor—the man who writes kind letters and sends us advertising matter, or the 30,000 at least *mostly* honest people who subscribe for GLEANINGS with the understanding that I am expected to be neighbor to each and *all of them alike*? May God help me to do my duty, even though it may offend at times.

Health Notes

THE DEPARTMENT OF AGRICULTURE AND ITS RAID ON MISBRANDING, ETC.

I have just received from the United States Pure Food and Drug Commission a great heap of leaflets in regard to the work the Department of Agriculture is doing. Let me mention briefly a few of them:

Dr. Caldwell's rheumatism cure. This was alleged to be "A certain cure for acute and chronic rheumatism in all its forms. . . . This medicine cures by expelling the acids from the blood . . . restores the liver, kidneys, and skin to a healthy condition, . . . thus effecting a permanent cure."

The Department sentenced him to pay a fine of \$200 and costs, particularly as the medicine contained 14½ per cent of alcohol, which was not mentioned on the label according to law. This amount of alcohol, like "Duffy's malt whisky," made the patient *feel* better for a brief time, but does not effect any such cures as claimed. This same doctor puts out anti-pain tablets, but does not mention the amount of acetanolid contained in them. This, too, was a fine of \$200 and costs. A confectionery called "whipped maple cream" contained no maple sugar nor syrup whatever. This incurred a fine of \$100 and costs.

"Wood's soothing syrup" is advertised to cure a lot of things, but it contains opium. The Department decided the circular was misleading and deceptive.

Absinthe is ruled out of our trade and

commerce, being pronounced "dangerous to the health of the people of the United States."

In conclusion, I hope the Department of Agriculture is supplied with men and money to go through the entire list of drugs advertised, and for sale in our drugstores; and may they not "be weary in well doing."

THE TRUTH ABOUT POKEROOT.

Mr. Root.—I have been scanning your pages for some time, expecting that some one would present the facts about pokeroot; but as confusion of ideas seems to continue I venture some additional information upon the subject. The botanical name of the weed commonly called *pokeroot*, sometimes "skoke," is *Phytolacca decandra*. Doubtless it has other popular names in different localities. In the New England States I have heard it called "garget root," because it is believed to cure a disease of the udders of cows, which causes bloody milk, and is termed "garget." This plant grows almost everywhere in the United States east of the Rocky Mountains. Whether it flourishes on the western slope of the continent I have not informed myself. Avoiding technicalities it may be described as follows:

The stalk is thick and spongy, growing from three to eight feet high, and putting out many oval-shaped lance-pointed leaves about three to six inches long, one to four inches wide; smooth, edges slightly wavy, and a dull green color above and lighter below. The whole stalk is killed to the ground by wintry cold, and shoots up afresh every spring. The flowers are arranged along slender amber-colored stiff stalklets often eight inches in length that spring directly from the main stalk and not from the point where leafstalks occur. They are very small, white, sometimes tinted with green, each floret having its own tiny stem, about a quarter of an inch long, and five roundish petals or flower-leaves. The centers are pea-green.

The root is branched, fleshy, somewhat fibrous in texture, and nearly white on being cut open. The sizes range from that of a finger to that of the arm. The flowers drop off, leaving a string of beautiful purple berries the size of a whortleberry (huckleberry), which adhere firmly to their

stems. Their juice gives a rich magenta stain. They have a sickly sweetish taste which sometimes tempts children, and causes poisoning. Starving migrating robins often devour them and are intoxicated. With one exception the whole plant is poisonous, causing vomiting, purging, convulsions, tetanoid contractions, and sometimes death. Several fatalities have followed cooking the root with vegetables.

Properly used, the root is a most certain remedy for chronic rheumatism, but requires skill and judgment in its use. The first early pale shoots that come up in spring are harmless, and make a welcome addition to mustard greens. When the stalk itself appears they should no longer be used. The plant is so splendidly ornamental that it should be more frequently seen.—H. A. Moody, M. D., *Professor of Materia Medica and Therapeutics, School of Medicine, University of Alabama, Florence, Alabama.*

I presume the above is authority in regard to the matter; but I do not quite agree with the concluding sentence—that is, if I understand it correctly. In Florida we clip off the young shoots, including a part of the stalk where it is certainly the size of one's finger, and we have cooked stalks and all repeatedly, and have never noticed any ill effects; and with the tremendous growth it makes, especially on rich ground, I do think it is worthy of cultivation as a garden vegetable. Perhaps it may be well, in localities where it has not been used, to eat it sparingly at first until you are satisfied it produces no ill effects.

BREATHING THROUGH THE NOSTRILS, ETC.

In GLEANINGS for Dec. 15 you make mention of a nasal trouble you have. Like yourself I like to get as much of God's pure air as I can, not only around me, but *into* me, and that through the proper

channel—the nose. For many years I tried hard to do all my breathing through the nose, and at last succeeded during the waking hours; but night time would find me sleeping with my mouth wide open, one or both nasal passages blocked up, and the top of my throat dry and distressed. Snoring, also, was often present. I tried various kinds of head harness to keep the mouth closed, but all to no purpose. They either required to be uncomfortably tight or else got shifted out of position. Some years ago a correspondent in the *English Mechanic*, replying to an inquiry, suggested a disc of celluloid to fit over or across the front of the teeth inside the upper and lower lips. I saw the point instantaneously, and made an oblong disc 3x1¼ from the rubber of an inside bicycle tube. After you cut it, just sandpaper the somewhat sharp edge; boil it for sanitary reasons; put it over the front of the teeth when you lie back on your pillow; and if you have cut a good fit you can not well breathe but through the nose, even if you wanted to do otherwise. When you rise in the morning, rinse it in water, and it will serve you for a year or two. Simple, is it not? Yet I can assure you \$100 would not tempt me to throw it aside. By the by, several years' use has not cured me of the habit of breathing through the mouth in sleep, as proved on several occasions, when I have tried to do without it. This may seem a small matter; but I can assure you it is not. Millions are suffering all sorts of dental, nasal, throat, and lung troubles, to say nothing about annoying others with their snoring, because they are inhaling through the mouth. We live a good part of our lives asleep, so let us do it properly.

Will you be good enough to pass this on to friend Terry?

By some means the address and signature of the writer of the above have been lost—something that rarely happens in our establishment. We have been holding it for some time, hoping to get track of the author. When he sees this, will he kindly assist us in giving him proper credit? Of late I have had so little difficulty in sleeping with my mouth closed that I have not tested the invention of our good friend.

Poultry Department

DRIP WATER FOR CHICKENS; A CHEAP ARRANGEMENT.

I herewith send you a description of a watering-fountain that is a little the best of any thing I have ever used. Get a wooden faucet and bore a hole near the bottom of a candy-bucket of such a size as to fit in tight. Set it in the shed so it will keep cool. Place it on a box up from the ground, and set underneath it a small galvanized dish that is easy to keep clean. Fill it with water and turn the faucet so it will just drip. By fill - the bucket once a day one will have a fountain that is cheap and easy to keep clean.

Okeene, Okla., July 7.

S. J. SPAULDING.

I would add to the above that I would have the water-bucket or half-barrel indoors on the north side of the shed in summer time, and on the south side when the weather becomes cooler and sunshine is more desirable; and instead of a galvanized dish I would have one of the cheap porcelain dishes, as they are easier to keep clean; and in place of the wooden faucet I would have one of the little brass faucets (or air-cocks), such as we buy of Sears, Roebuck & Co., for 15 cts. each. I like the brass faucets better, because they do not

need so much adjusting. The wooden ones swell and shut off the water unless you let it run so fast as to waste.

DUCKLINGS; WHY DO THEY DIE?

Would you advise me how to feed young ducks? Mine grow nicely for a time, then become unable to walk, and die. I have been feeding bran and shorts. Orangeville, Ont.

R. J. GALBRAITH.

Bran and shorts, or middlings (wet up) is all right; and when they get a little older, put in some corn meal; and water to drink must *always* be close by the feed. If you have been reading our journal you must have noticed what I have said about green food, especially lettuce. Give them all the lettuce they can eat, and I don't believe you will have any trouble. I suppose other green food will answer, but lettuce they seem to prefer to any thing else; and if they are not where they can get insects, etc., they must have some meat or some sort of animal food. Fresh meat from the butcher's, or bones ground up in a mill will be all right.

Temperance

PROHIBITION ON THE FARM AS WELL AS ON THE RAILWAYS.

This is the way the *Rural New-Yorker* looks at it:

For years American railroad men have been forbidden the use of intoxicating liquors while on duty. Rum spells ruin to the men handling such a powerful force as a railroad train—the same as it does in smaller enterprises. The D. L. & W. R. R. Company has now gone a step further in prohibiting the use of liquor, with the following order:

"The use of intoxicants while on or off duty, or the visiting of saloons or places where liquor is sold, incapacitates men for railroad service, and is absolutely prohibited. Any violation of this rule by employees in engine, train, yard, or station service will be sufficient cause for dismissal."

Now, seriously, there is not a person who ever travels on a railroad who will not agree that this order is right. There is not a brewer, distiller, or saloonkeeper who would knowingly give the liquor he sells or makes to the railroad men who handle the train whereon he rides! That being so, why stop at the railroad business with prohibition? There is no business on earth which does not face loss or possible ruin when workmen are free to drink liquor when "on or off duty." There ought to be just such handling of farm laborers, for rum has caused more loss and sorrow to farm homes than it ever did to the railroad business.

SOMETHING MORE ABOUT THE DRUNKEN ENGINEER; "FORTY LIVES BLOTTED OUT, AND SIXTY CRIPPLES MADE."

The fast express train was taken out of Elmira, New York, the other day, for the run to Buffalo on the Lackawanna Railroad. It had on board valuable property and still more precious lives. It went along safely until it approached Corning, and then it ran into a limited passenger train, piled up a wreck of engines and cars, killed forty persons, and injured sixty others.

What was the cause of the disaster? The engineer was drunk. Under the stupor of liquor he passed by the danger signal, paid no attention to the warning fusee that was burning, and disregarded the fluttered cloth of the flagman who had been sent back from the other train to flag him. "Booze" had made him dull.

One more is added to the long list of horrors due to drink. It is a black record. It is the most powerful sermon for total abstinence that could be preached—hundreds of thousands of dollars' worth of property destroyed, forty lives blotted out, and sixty cripples made—all by one man who was drunk.—*Catholic Columbian*.

SAWMILL OR SALOON—WHICH IS THE MORE DANGEROUS TO HUMANITY?

I presume it's comparatively well known that manufacturers are being held more and more liable for damages resulting to workmen using dangerous machinery. If a man is hurt in a sawmill, when he uses ordinary care, the owner of the mill is held responsible. But how about the owner of the saloon? Here is something in regard to the matter, which we clip from the *American Advance*, and it also gives us a little further glimpse of this same Gov. West:

Mr. Edward H. Todd, of Salem, Ore., has noted that Governor West, of that State, favors a "just compensation law requiring the saloon as well as the sawmill to care for its maimed." It is Gov. West's theory that the saloon should no more ask the taxpayer to care for the man whom it has made insane or a pauper, than that the sawmill proprietor should ask the public to care for the man who loses his limb because of the misbehavior of a buzz-saw.

THE BEER BUSINESS AND OUR BOYS; CONDITIONS IN SPRINGFIELD, O., SINCE

SALOONS ARE AGAIN RUNNING.

We clip the following from the *American Issue*. What do you think about it?

A few weeks ago the writer, while crossing the bridge over the Pennsylvania R. R., two and one-half blocks from police headquarters, saw six boys, ranging from nine to fifteen years, drinking from a bucket of beer. Being inexperienced they were having quite a lot of trouble with the suds on top. One little fellow, while down on his knees drinking, stopped long enough to say that it was awful bitter, but he guessed he could drink it.

"LIFTING UP" THE FARMER.

Here is something more from the *Rural New-Yorker*:

Says a country clergyman of wide culture and experience: "I don't like to hear about 'uplift commissions' to country people. It sounds as though we others are so far above them that we have to reach down to pull them up, which is taking the wrong standpoint from the beginning."

To the above I give a hearty amen. Just a few days ago a very nice letter came, informing me that I had been recommended as one of a commission to visit foreign nations to investigate their system of making it easier for farmers to borrow money at low rates of interest. If I understand it, the government was to pay all expenses. Now, perhaps my opinion comes from a narrow point of view; but I do not believe the farmers of the United States, as a rule, need any such uplifting. So far as I know, they get all the money they need already, at very liberal rates of interest. There are other people in our nation who need uplifting vastly more than the farmers; and it seems the fellows who are continually inventing excuses to get some appointment to uplift the people, and have Uncle Samuel pay the expenses while they are abroad, do it to put on the style of millionaires, and have the farmers and laboring men foot the bill.

A KIND WORD FOR FRIEND TERRY; FRUIT SUPPERS, ETC.

Mr. Root:—For a long time I have been intending to write you a letter of appreciation. You recently published in GLEANINGS my letter to friend Terry, and I also want to express to you my gratitude for introducing your readers to Mr. Terry and his valuable teachings. It was through you I first learned of him, and it has proven a Godsend to me.

I am following Mr. Terry's advice almost to the letter; yet in one thing I am following you—that is, in regard to time of eating my meals. As I work for day's wages at present I find it impracticable to eat at Terry's meal hours, so I decided to do as you do. I eat breakfast at seven, dinner at noon, and then a lunch of fruit in the evening. I eat no supper. This plan has worked nicely with me, and is more convenient in my present circumstances.

I greatly enjoy all of your Home papers, and I trust you may live long to continue your battle for right. GLEANINGS is an ever welcome guest, and I admire it for its high moral tone.

JOSEPH H. PETERSON.

NO. 18

Editorial

WHY DOESN'T THE AVERAGE PRODUCER GRADE
HIS COMB HONEY?

ONE large buyer complains that the average producer does not grade his comb honey at all, or else does it so poorly that the honey has to be graded again before it is fit to send out. If this is true, it is small wonder that he cannot get good prices. As a general thing the buyer charges for re-grading, at a price that will make it possible for the producer to make big wages if he would do it himself. Dealers, other things being equal, will buy continuously of the man who grades honestly and intelligently, so he knows every year what he is going to get when he orders a fancy, No. 1, or a choice.

We respectfully suggest that every beekeeper use the grading rules adopted by the Colorado State Beekeepers' Association.

UNIFORM GRADING RULES.

In our issue for July 1 we endorsed the grading rules adopted by the Colorado Beekeepers' Association. We knew nothing about what Editor Tyrrell was going to say on the subject, and he was ignorant of what we were to say; but apparently he was of the same mind as ourselves, as is evidenced by the *Beekeepers' Review* for July. We are now informed that the suggestions made by both of us are to be carried into effect by the National Beekeepers' Association appointing a committee of honey-producers and honey dealers to formulate a set of grading rules which it is hoped will be adopted by beekeepers of the East as well as of the West. Good! With some slight modifications the Colorado rules could be made to fit Eastern beekeepers.

SHIPPING BEES WITHOUT COMBS, AGAIN.

ON page 502, Aug. 15, we referred to the possibility of shipping bees long distances, even in car lots, without combs. For some years back we have made a practical success of shipping bees in pound and half-pound lots all over the United States. So far no obstacle has been encountered ex-

cept during extremely hot weather such as we have been having for the last few days. During such torrid spells some packages do not go through in the best of condition. The probabilities are that the express handlers pile other packages over the packages of bees, completely shutting off the air. When bees suffer from want of air, water seems to accomplish wonders. We are, therefore, during this week of exceedingly warm weather, trying the sending of packages of bees equipped with bottles of water. We shall be glad to give our readers the results of the experiments.

We sent three pounds of bees in one package to Dr. C. C. Miller, and the report came back promptly that only four of the bees were dead. We sent a like package to Dr. E. F. Phillips, of the Bureau of Entomology, Washington, while the weather was extremely warm, and the bees arrived there in bad condition. To-day, Sept. 10, is one of the hottest days we have ever known, and we are just sending another 3-lb. package to Dr. Phillips, with a bottle of water.

At this time of the year 3 lbs. will take up all the bees of a fair-sized colony. Assuming that brood-rearing has stopped, it would be possible to ship several hundred 3-lb. packages of bees, and put them on other sets of combs on arrival at destination. But we will not build any air castles until we see how our little air castles grow. More anon.

HONEY-CROP CONDITIONS.

FREQUENT rains over the country, especially east of the Mississippi, and the extremely warm weather, have stimulated the secretion of nectar, not only from belated white clover but from alsike and the second crop of red clover. There has been reported a fine fall flow in many sections from asters and goldenrod. Some reports from New York indicate a failure of buckwheat. A representative has been up through the Northwest in Wisconsin and Minnesota, and he reports there will be

more clover honey than was originally indicated.

In our last issue we stated that the opinion prevailed that there was a large amount of clover honey still held back. Later reports continue to confirm that view.

Apparently *extracted* honey has reached its high-water mark of price. We hope it will hold its own. This only goes to show that beekeepers have been running too much for extracted honey and not enough for comb. The hard logic of facts, too much extracted, and a scarcity of comb honey, should convince us that we should run more for comb honey. There never was a time in all our experience when No. 1 and fancy clover comb honey did not have a good market. We do not believe it is possible to produce too much of it any season.

The conditions for a honey crop next year were never more promising. Reports show that there is more white clover on the ground than has been known before for many years. Beekeepers should begin to make preparations to produce comb honey.

A DISTINGUISHED VISITOR AT THE HOME OF THE HONEYBEES; RUSSIA'S COMPLIMENT TO AMERICA.

We have just had the honor of a visit from Dr. Ivan Kablukov, Professor of Chemistry at the Royal University and Agricultural Institute of Moscow, Russia. He had been sent by his government to attend an international convention of chemists at Washington, D. C. As he was making bee culture more or less a study he was commissioned by his government to make us a call, which he did. He seemed very much delighted with every thing he saw, and more than once expressed his surprise at the immensity of the beekeeping industry in the United States, as evidenced by the buildings and general equipment that go to make up the plant known as the "Home of the Honeybees." He used his notebook freely, and doubtless will be able to transmit to his government a good deal of valuable information on the possibilities of beekeeping in Russia; for what has been done in the United States may be accomplished in that great country.

It will be remembered by some of our readers that in 1903 the Russian government also sent Mr. Abram Titoff to this country to study American beekeeping. He spent two full seasons here, and proved himself to be not only an alert but an efficient and intelligent workman among the bees. He later spent a couple of sea-

sons in California and then he went back to his own country in April, 1906. Now, according to Mr. Kablukov, he is inspector and teacher in bee culture in Kieff, Russia. We of America ought to be proud of the fact that a great country like Russia considers our methods worthy of adoption.

BEE EXHIBITS AND BEE SHOWS.

ALMOST every department of apiculture has been represented in books relating to bees except the science of making exhibits of bee products at fairs and shows. But even this field has now been very amply covered in a new work just out by Mr. Wm. Herrod, F.E.S., junior editor of the *British Bee Journal and Beekeepers' Record*, London, England. This little volume contains nearly 175 pages, with appropriate illustrations, especially of many prize-winning exhibits at the various shows in England. The author discusses the question of producing, preparing, and judging exhibits of bee products in a most thorough and painstaking way. While the manner of preparing these exhibits is somewhat different from the general scheme in vogue in the United States, yet any American reader will gain from it many helpful suggestions. "Mr. Herrod," in the language of Mr. Thos. Wm. Cowan, senior editor of the *British Bee Journal*, "has had more experience in managing the largest and most important shows in the country than any one else; and in this book we have the practical results of his experience clearly stated for the benefit of those desiring to produce and prepare exhibits with some expectation of gaining prizes."

The price of this book is not stated; but information can be secured by writing to the office of the *British Bee Journal*, 23 Bedford St., Strand, W. C., London, England.

A NEW BOOK ON BEEKEEPING BY PROF. H. A. SURFACE, OF THE DIVISION OF ZOOLOGY, DEPARTMENT OF AGRICULTURE OF PENNSYLVANIA, AT HARRISBURG.

A NEW book or bulletin on bees, by Prof. H. A. Surface, Economic Zoologist at Harrisburg, has just been received. The author, well known to our readers as one of the leading lights on beekeeping in his State, has come to be almost a national figure. A trained scientist, he not only keeps bees himself, but has for years been conducting a series of experiments in practical apiculture; and we believe we are quite within the truth when we say that he is not only authority in scientific apiculture but in practical apiculture as well.

He is an indefatigable worker. His correspondence is voluminous, for he never seems to tire in rendering helpful advice, not only in zoological matters but in telling the farmer and the fruit-grower how to grow more and better crops, as well as how to combat insect enemies with which they have to contend. We are glad, therefore, to recommend this bulletin on practical apiculture, because we believe its advice is sound and safe.

It contains over 70 pages of matter, with original illustrations by the author. This latter feature is quite unique in a work of this sort, because many modern bee books consist of a series of illustrations that seem to be more or less "common plunder." But Professor Surface has not borrowed a single cut. The whole work from beginning to end is distinctly original.

Nothing is stated as to how this book can be obtained; but we presume that any resident of Pennsylvania can secure it free of charge by making application to the Pennsylvania Department of Agriculture. Ask for Zoological Bulletin, Vol. II., No. 3, entitled "Beekeeping, by Prof. H. A. Surface." Persons living outside of Pennsylvania will probably have to pay a moderate fee. A letter addressed to the Department of Agriculture, Harrisburg, will doubtless bring the information.

A NEW GOVERNMENT BULLETIN ON COMB HONEY; HOW TO SOLVE THE SWARMING PROBLEM.

THERE has just come from the Bureau of Entomology, Farmers' Bulletin, No. 503, entitled "Comb Honey," by Geo. F. Demuth, Apicultural Assistant in the Bureau of Entomology. For several years Mr. Demuth was foul-brood inspector for Indiana. Prior to that time (and even afterward) he was one of the most successful producers of comb honey in the country. When we say "successful" we mean he made money at the business year after year. Now that the production of comb honey, because of difficulties, is getting to be neglected, a bulletin that can be obtained free for the asking, telling how one can overcome those difficulties and at the same time make money, is particularly opportune.

We have read this bulletin with considerable care, and we believe that, from every point of view, it is not only orthodox, but one of the best if not the best treatment of the subject we have ever seen. Some of the methods advocated are old, and some others are practically new.

A plain standard Langstroth hive with

the usual super equipment is illustrated and described; in fact, the paper is full of original illustrations showing hives and supers in a variety of combinations. Plain and beeway sections and their supers are clearly shown by line cuts. The merits of the extracting supers, combination supers (for both comb and extracted honey), and bee escapes are all carefully considered.

The manipulation of the bees to secure a crop is taken up very minutely.

The author's treatment of swarming deserves a most careful reading by every one of our subscribers. As swarming is one of the serious drawbacks if not the most serious in the production of comb honey, the man who contemplates producing this product will do well to learn how Mr. Demuth eliminates the nuisance. Perhaps not all will agree with him as to the theory of swarming. He says, "It is possible to manipulate all colonies before any swarming occurs so that most of them go through the honey flow without swarming, *thus eliminating the weekly examination.*" Italics ours. We are in position to know that he has done what he says he can, and that, too, without the purchase of any special appliances other than those in possession of beekeepers generally over the country. Now, then, listen: "Any manipulation for swarm control," he says, "whether applied after the colony has acquired the 'swarming fever' or applied to all colonies alike previous to the swarming season, is based upon the single principle—a temporary disturbance in the continuity of the daily emergence of brood." The italics in this case are those of the author. He goes on to describe the different methods for controlling a swarm, and says that by each one of these methods "the temporary disturbance in the continuity of brood is an important factor in the process."

For some time Dr. E. F. Phillips, in Charge of Apiculture at the Bureau, has been looking for a comb-honey man—one who is an expert in the practical treatment of bee diseases. That he made a wise selection will be agreed to when the beekeepers of the country come to review this bulletin. We predict that the entire edition will be exhausted in very short order; and any one who desires to secure a copy should speak at once, before the edition is all gone. This bulletin may be obtained free by addressing the Secretary of Agriculture or any Member of Congress. Ask for Bulletin 503, entitled "Comb Honey," by Geo. F. Demuth, Bureau of Entomology.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

THAT EXTENSION wheelbarrow, p. 561, looks like a good thing. Might be, well, though, to shift the platform a foot or so forward. That would make it lighter to lift.

DR. KRAMER says, *Schweiz. Bztg.*, 217, that a young queen produces progeny of lighter color than an old one, and that a queen that is old but still vigorous is better to breed from than a young one.

MR. EDITOR, your objections to having honey stored below the brood-chamber are correct; and if sections are produced, there's another objection, the cappings will be badly darkened. I've tried it, p. 564.

S. E. MILLER, it is true that your method of numbering hives, p. 485, makes it "not necessary to walk around to the side or end of the hive" to see the number; but I'd rather save my head than my heels, and with plain tags I don't have to do any figuring as to what the number is. Besides, you probably didn't think of my cellaring bees, and your plan would hardly work in the cellar.

I. HOPKINS, p. 480, rightly says that what is called the Dines method of queen-rearing originated in Australia, leaving a little uncertainty as to when it was first published. Prior to any date he gives, it was mentioned in a *Straw*, April 15, 1909. The fact that little or nothing has been said about it in foreign journals since that time looks a little as if the plan had not panned out well.

PERCY ORTON is quite right, p. 334, in saying that European foul brood does not *always* injure a queen. A light case seems to have no effect on a queen. Ye editor seems to hold that European foul brood never injures a queen. I think E. W. Alexander held that it generally does. I believe that a severe case always injures a queen—not that she has the disease, but living in the foul atmosphere lowers her vitality, making her dull and inactive. [If it is true that European foul brood generally injures the queen, we confess our ignorance, and stand corrected.—ED.]

DR. HERING, RUNDSCHAUER of *Deutsche Bienenzucht*, says, page X., that he agrees with the views of the editor of *GLEANINGS* about wintering; but he objects to cellar wintering, for he thinks the free dry outdoor air, full of oxygen, the most favorable to the health of bees. Right you are, doctor; you can't emphasize too strongly the importance of good air. But our cellars

with furnaces may be kept so open that the air in them is just as good as outdoors. [The logic of the past season (and there is nothing like facts) argues pretty strongly for cellar wintering for extremely cold winters or very cold climates. A great deal depends on the kind of winter, the sort of exposure, whether the bees are wintered outdoors, and the kind of protection. If they are wintered indoors the kind of cellar, the amount of ventilation, and the humidity are factors that must be considered.—ED.]

T. B. TERRY says, *Practical Farmer*, 416, that honey is said to have the same wholesome sugar as in sweet fruits, "but it is in condensed form, so do not eat it clear or in large quantities for best results." He also says, "I consider choice butter a safe form of fat." Bro. Terry, didn't you forget to add the caution, "but the fat in butter is in condensed form, so do not eat it clear or in large quantities for best results"? Isn't there as much danger of eating butter clear as in large quantities of honey? Do you think there's half as much harm done to those who eat honey clear or in large quantities as the harm done to the thousands of poor ill-nourished children by never getting a taste of it? Long may you live to preach the gospel of keeping well.

A STRANGE SEASON this. It promised a dead failure, very little clover in sight, with feeding till last week in June, then a growth of clover coming from nowhere and increasing to a splendid flow with never a break till the fall flow began the last of August; and at this date, Aug. 29, the bees are piling in the honey from white clover, sweet clover, heatsease, and possibly other things. Others complain that cool and wet days have hindered gathering. Same here. At this very minute, 9 A. M., it is cool and cloudy—wait a minute. . . . Just been down to the yard, and hardly a bee flying. But I'm not complaining of the cold rainy days. They're a blessing—prolonged the season by just that much. Already I've taken 96 sections from each of four colonies, with perhaps 75 nearly finished sections on each hive, and more to follow. But with all that, mind you, the crop is short. The bees are not in the country. [Was there ever a year when clover held on so well? If so, we do not remember it. Even now, Sept. 1, it yields a little—almost enough to take care of the daily consumption for brood-rearing. As we have never had a fall flow to speak of, it comes in very handy.—ED.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

The honey season about here began June 22 and closed July 20, lasting just four weeks—three weeks on clover and a week on basswood. We have a very good crop.

* * *

Thanks for C. A. Bunch's description on page 454, July 15, of a sweet-clover-seed stripper. I might have saved a lot of seed two years ago if I had known how; but I supposed it had to be drawn to a barn floor and thrashed like grain to get the seed.

* * *

That editorial, page 431, July 15, in regard to the use of glass in shipping-cases, and the statements by Mr. Hathaway, page 454, are quite to the point; and yet there are some markets that will call for it for a long time to come, I fear; and not only cases with glass but sections as well.

* * *

Mr. E. W. Peirce, page 409, July 1, hits the nail squarely on the head when he tells us that we can not expect the price of honey to go above a certain figure. This is most certainly true with the great mass of consumers; and yet there are some who will pay fancy prices for honey if they can not get it without doing so.

* * *

Louis H. Scholl gives us a "chunk" of bulk comb honey to think about, p. 434, July 15. Now, I would like to ask him frankly if he would advise the beekeepers of the North to put up bulk honey in tin or glass, and pour over it choice clover or linden honey that granulates quickly in our cool climate, and then ship to the cities to wait for customers. What is best for him may not be for us, although I have a friend here in Vermont who is quite enthusiastic over "bulk comb honey;" but he sells near home.

* * *

I am not exactly glad that Orel L. Hershiser has had foul brood among his bees, but that, having had it, he can tell his experience as he has done on page 299, May 15. European foul brood or American foul brood in the hands of an earnest or industrious beekeeper is not the scourge it is usually considered. I visited one town last year where every yard, so far as I know, was diseased, and it seemed a hopeless task to clean it up; yet by following a few simple directions these same yards to-day are almost free from disease. One yard of black bees where almost every colony was diseased,

I found on a recent visit entirely free, and as clean as one would care to see. But I see the finish of the careless farmer beekeeper in the near future, and the whole business left in the hands of those who will care for their bees.

* * *

J. L. Byer, p. 264, May 1, says that it is hard to explain why a cross between Italian and black bees should be called a hybrid. Well, my friend, I will tell you. When Italian bees were first introduced into this country, or before, they were described as most wonderful bees—very distinct from the common bee, and much larger than black bees. It was claimed, too, that they would work on red clover. The conclusion was drawn, that of course a cross, if it would cross with the common bee, must be a hybrid; and since that time we beekeepers have kept right on using the word in a wrong way when we knew better. Is there time for repentance? I think so. Why not call all the various crosses between the different breeds of bees "grades," as is done with cattle and sheep? Is a cross between a Carniolan and a black bee a hybrid? Then why should a cross between an Italian and some other breed be called a hybrid?

* * *

Mention is made, May 1, p. 273, by Dundas Todd, of hiving a swarm by first using a little smoke. It is a popular idea that smoking a colony of bees clustered on the branch of a tree is ticklish business, for smoke frightens them and then they will all leave for the woods. I myself used to be afraid that, if I smoked a cluster, the bees would immediately run away. I have now used smoke for this purpose for more than thirty years, and never yet have driven a swarm away. Smoke is even more helpful in making bees gentle when clustered than when in the hives. Besides, they often cluster in fence-corners or on branches where one can not readily dislodge them or saw off the limb, and smoke is exceedingly helpful in driving them to a place where they can more easily be hived.

Speaking of the value of ground cobs for packing, p. 259, May 1, the editor commends this material because of its capability of absorbing water. I had supposed that the value of packing material consisted in its ability to hold air. I don't want any water in the hives or packing, and there will be little in either if good provision has been made to get rid of it.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

On Aug. 27 I leave, by motor cycle, for a ten days' trip among the beekeepers of Southern California. While my time will be too limited to extend into the central and northern valleys this year, I hope to be able to cover that territory another season and get acquainted with the beekeepers and their methods.

* * *

Bees in many localities are doing very little, with little prospect of late nectar to stimulate breeding. I would not be surprised if the stock for wintering would be rather low, causing a shortage of bees for spring breeding. Some localities, however, continue to yield from various sources sufficient to keep a good amount of breeding going on and colonies strong.

* * *

The following dispatch is taken from the Redlands *Daily Review*, and dated at Los Angeles, Aug. 24:

That Geo. B. Larinan's bees ate 12 acres of strawberries, thus depriving the market of that amount of fruit, to his damage in the sum of \$1500, is the allegation in the complaint filed to-day in the superior court by T. Katoaka.

The suit is an action in trespass, Katoaka in his complaint alleging that the bees "in great numbers, flew, roamed, foraged, and trespassed upon the plaintiff's land without his consent, and ate up, injured, and destroyed the berries, being the growing thereon."

Katoaka's ranch is located in the A. B. Chapman rancho and Larinan's apiary of 200 hives is on adjoining property. In addition to demanding damages for the alleged destruction of his berries, the plaintiff seeks an injunction to prevent Larinan from maintaining his hives on contiguous land.

* * *

Five big meetings for beekeepers were scheduled for the summer as follows: Aug. 3, Dinuba; Aug. 12, Santa Paula; Aug. 14, Redlands; Aug. 19 and Sept. 6, Los Angeles. These meetings were held under the direction of Mr. J. B. Neff, representing the Agricultural Department of our State University, speakers being furnished by the State Association, from its membership. The boys were wide awake to the interests of beekeepers in general, and especially to the necessity of awakening a general interest among those who are not organized in counties or affiliated with the State association. The officers of the State Association have some fine plans laid, and expect to make the Association membership worth many times what it costs. The meeting at Dinuba was a big success, also at Santa Paula, while the one at Redlands was so far ahead of expectations that every

one was well pleased. Some old-timers were here, including Mr. T. O. Andrews, of Corona, and Mr. A. T. Wagner, of Imperial Co. A variety of subjects were on the program and all were handled with skill. Meetings outside of the big schedule are also being planned, one at Covina having already taken place. California beekeepers should be thankful that we have energetic men at the head of our State Association who lose no opportunity to advance our interests.

* * *

I am in receipt of a letter from Mr. M. E. Richter, editor of "Honey Plants of California," who is now located at Santiago, Chili. Mr. Richter writes me regarding the sage-worm, on which I commented in the Jan 15th issue. I quote from his letter: "You say you observed their abundance in off seasons when the sage is less thrifty, and that you are of the opinion that the weather has no influence thereon. My observations were made in Ventura and Santa Barbara counties, and, of course, during the flowering months of the sage. With many cloudy days during April and May the sage-worms were numerous; but with the first real warm weather in June there was a marked diminution in the worms, and they were invariably found on the north side of the whorls. Such seasons were, to be sure, off seasons, and the sages were not thrifty, for they lacked the necessary warm weather. With bright warm sunshine, however, in April and May, the worms were inconspicuous, and the season was good." In justice to Mr. Richter I have quoted the above, though my ideas are somewhat different from his. Some features of this season would seem to prove his contention, while others do not.

The sage-worm, or weevil, as I have previously styled them, were the worst, to my knowledge, this season, and the weather through April and part of May was surely very bad, which would bear out Mr. Richter's contention. On the other hand, the weather after May 12 was very warm and clear for a number of days just at the time this pest was doing its worst, and cutting the life out of the buttons. The season of 1905 was the coldest and most backward I have ever seen, yet there was not a weevil, but an enormous honey-yield, nearly all of which came after May 15. The following season, with bountiful rains and open spring weather, the weevil was quite plentiful, and sages yielded meagerly. I will make further observations next season.

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

WHY SWARMS CLUSTER.

Mr. Anthony's theory, as related by the editor, page 502, Aug. 15, is a new one to me, and one in which I am not inclined to take much stock until further and more convincing proof is furnished. There may be something in it; but, according to the old saying, "one swallow does not make a summer." I hardly believe that the one instance alone shows that the killing of the remaining virgin in the parent hive had any thing to do with the return of the swarm from the tree-top. Swarms with virgins often do strange things, generally leaving for parts unknown as soon as they emerge from the hive. Yet, on the other hand, we have had such swarms hang about the yard for a day and even more, trying, perhaps, to gain entrance to some other colony. We have hived swarms with virgins after the bees had actually clustered instead of running away to the woods as might be expected, and then had them return to the old hive from which they had issued.

HONEY-CROP REPORTS INTERESTING.

It is strange how much more interesting the reports are when we have had an unfavorable season. This may be partly due to curiosity to see whether other beekeepers have fared better or worse. In one way the reports this year serve as a consolation, as they show that some others are faring no better. This year, for instance, we do not feel our loss so keenly, as there seems to be a rather short crop, taking the country as a whole; for, except in the case of a small portion of the country, there seems to be but a partial crop after all. We can be thankful, at least, that we need not fear having to feed our bees to carry them over until next year. It is true that there are a few localities where feeding will probably have to be done, since the rains delayed too long to help out in the fall.

Honey prices should rule a little better this year as a consequence of a general shortage of the crop. The Western honey seems to be a good deal more scarce than the Eastern. Some parts of the South have had good crops; but that in Texas is unusually short, especially since there has been an almost entire failure in Southwestern Texas, the main honey-producing section.

But since the fruit and syrups have been so plentiful the price of honey is not so very much higher after all, for honey is

still considered more as a luxury than as a necessity. This means that, as soon as the price of honey goes higher than usual, other things are substituted in its place, if they can be obtained at a reasonably fair price. Peaches and other fruits happened to be very plentiful this year, so that they have filled the demand for sweets to such an extent that less honey has been purchased than usual. The abundance of other fruits accounts for the large amount of preserves that have been put up; and these preserves, together with the large amount of sorghum syrup made this year, accounts for the smaller demand for honey. It will be remembered that fruits and syrups were more or less a failure last year, so that the demand for honey was far greater. However, in spite of all this the price of honey has gone up half a cent per pound or a little more over last year's prices, and it will be no trouble to sell all that has been produced before the end of the fall.

THE AUTOMOBILE A SIGN OF PROGRESSIVE BEEKEEPING.

One of the most pleasing indications of more progressive beekeeping is found in the constantly increasing use of automobiles by beekeepers. In itself, the ability to own an automobile usually indicates that a beekeeper is more or less progressive, or that he is possessed with progressive ideas at least. As a rule, the purpose of procuring an automobile is not only for use as a pleasure machine but more as a real business proposition. That the automobile is coming to be acknowledged more and more a much needed addition to the beekeeper's equipment, especially for real progressive beekeeping, is well known. The beekeepers who are taking advantage of this fact have the assurance that they are prepared to accomplish not only more work, but to do it better, while at the same time more pleasures can be enjoyed, both doing his work and while at leisure.

The automobile has come to stay, and the time is not far when a good "machine" can be obtained at a very reasonable price. Fortunately, the great number of different makes of automobiles, together with the wide variation in price, makes it very easy to make a selection best suited to the needs and the pocketbook of the beekeeper. Once purchased, there is no doubt an automobile will pay well, provided, of course, there is use for one.

Conversations with Doolittle

At Borodino, New York

SEPTEMBER PREPARATIONS FOR WINTER.

"When is it best to make preparations for winter? I have always waited till the advent of cold weather; but I was asked yesterday if I had my bees ready for winter yet, and this set me to thinking whether I had not been a little late in my work for the bees to winter to the best advantage."

"I have believed for some time that too many of us wait too late in the season before making the needed preparations for winter. Here at the North the wintering of bees is one of the great problems, if not the greatest; and to neglect it through ignorance or carelessness is little short of criminal."

"But you would not begin preparations as early as the middle of September, would you?"

"I certainly would. For the past twenty years I have often commenced the latter part of August. Years ago, at a convention an old beekeeper who had succeeded better than the most of us gave out this as the secret of his success: 'The time to begin preparing for a good honey flow is the season before.' I have always remembered this when about to put off something which needed immediate attention; and with a little modification the same statement applies very nicely to the preparation of colonies for wintering. And the best part of it is, such preparations place the bees in the best possible condition to be in readiness for the next year's honey flow."

"But you would not pack your bees for winter yet, would you? A good many of the supers are still on in my yard."

"The old advices in regard to getting ready for winter dealt almost wholly with packing, sufficiency of stores, ventilation, amount of entrance room, etc. Now, these things are necessary, but it is just as important to look after the age of queens, the proportion of young bees, and the number of bees in each colony. Can any of these be changed after winter sets in, or even after October, here in the North?"

"Sufficiency of good stores also should be included as another of the necessary preparations which should be looked after as early as this; and the month of August is much better unless one lives in a locality where a surplus yield can be expected from fall flowers. The mass of beekeepers usually defer these necessary winter preparations until late in the fall, when it is

too late to remedy any defects which are discovered at that time, regarding the general condition of the colony. I am well aware that stores may be given in November, and even in December, by way of frames of sealed honey. But this can not be done with the assurance that it will be conducive to as perfect wintering as would have been the case had such frames been given at this time, which allows a sufficient number of warm days for the bees to adjust such stores all about the cluster, as they always will do where they have the needed time.

"With all of these things attended to at the proper time, a condition is brought about which very largely measures the success in wintering, regardless of those things so much stress has been placed upon during the past. The fact remains that, if a colony is provided with a vigorous queen, plenty of young bees in proportion to the older ones, so that a cluster of suitable size is in control of the combs which contain ample stores of good quality within easy reach, many of the so-called essentials have very little to do with the safe wintering of such colonies. Therefore this work of preparation should begin immediately after the close of the honey harvest, to give the best results. But if, under special stress of circumstances, it can not be done then, should the weather continue favorable, fairly good results may be expected if all colonies receive the necessary attention prior to the first of October."

"What would you consider a vigorous queen?"

"One which has brood in the hive at the close of the honey flow to the amount of two to three frames full, with a good quantity of bees of all ages besides. Two frames of brood give about 12,000 bees, and three frames about 18,000. Now, if the queen retrenches at the close of the nectar flow, so that she can lay a little longer, then there will be perhaps 20,000 bees from this brood, all of which are sure to be young, and full of vitality for wintering purposes. And, in addition to these, there will be at least half as many more that emerged prior to the close of the harvest, and these will be pretty fair for winter so that the colony will contain not far from 30,000. Such a colony as this, in a ten-frame Langstroth hive, with a proper amount of suitable stores, insures it in a great measure for the next year's honey flow."

General Correspondence

CANDOR AMONG BEEMEN

Why Orders for Bees or Queens Should be Filled Promptly, or a Postal Sent Explaining why Delivery Can't be Made then, but Stating when they can be

BY LEWIS P. TANTON

In a recent issue of *GLEANINGS*, business candor was advocated, especially in relation to queen deliveries. The average purchaser, dealing with the different supply houses, can emphasize the necessity for this caution, in many instances. To save the loss of a valuable queen a frame or two of brood is wanted, or a queenless hive is in danger of extinction for want of a queen. An order is dispatched to a dealer who loudly advertises promptness. Not a word of explanation, not a line of reply, until you lose your patience, and, not unlikely, the bees you are trying to save, and then the article will come when you have no use for it. I have before me a letter saying, "I will send you two untested Italians Monday or Tuesday." Those queens were not mailed as promised; considerable loss and inconvenience are incurred, and I am left in ignorance as to when or if they will ever be sent, and thus am at a loss to know whether to order elsewhere or not.

Another dealer quoted this spring on bees, "up to 100 hives." I ordered one hive, to be shipped *at once*, by express, saying I wanted it immediately to get brood to save a weak colony, with a valuable queen. Over a fortnight after he received my order he replied, "I will ship next week." My queen died in that time, so I canceled the order.

Now, in both cases a post card, promptly sent, would have enabled me to order from other sources, in ample time to save my bees. I refrained from doing so, expecting those already ordered to arrive at any moment.

My experience is, no doubt, that of thousands all over the continent who have been similarly "stung." These dealers foolishly imagine that, by this process, they retain trade. The opposite is the case. The burnt beekeeper, like the burnt child, dreads fire. The slothful dealer may retain the proceeds of his first sale; but that transaction ends his business relations with that customer, most likely, forever.

This candor should always be exemplified in the description of the goods offered for sale. I once purchased several two and three frame nuclei from a dealer in Massachusetts. One of these, a three frame,

weighed about eighteen pounds in a light shipping-box, threw off a strong swarm, and yielded 110 lbs. surplus honey the first season. All this lot (8 nuclei) was nearly as good. At the same time I received a so-called full colony from another dealer, in a Langstroth hive. Bees, combs, and all weighed just 23 lbs.; had a hybrid queen; made no increase, and very little surplus honey. Which of those dealers do you think will command respect and hold trade? I have had dealings with the first of these for many years, and it is like doing business with a bank, for reliability and uniformity. One transaction settled me with the latter.

As a class there are no more upright people in the world than beekeepers. Those who are dishonest are, in reality, freaks, and scarce. Much that appears irregular is laziness or carelessness. The bee is the world-wide emblem of industrial nature. The beekeeper, to ensure success, must study and imitate his subject. Doing this brings him in closer touch with the operations of nature and nature's God. This contact develops diligence, frankness, and the higher ideals of honor in his interpretations of the responsibilities of business life. The one who fails to profit by the teachings of his busy exemplars will show an ill-kept apiary, a long list of dissatisfied clients, and all the evidence of a wasted business experience.

Do you notice that the most generous and public-spirited of beemen are of that class who study their subject the closest? Can you account for it in any better way than by ascribing it to the affinity of two great industrial natures, the man and the bee? The bee gives a full comb and full weight. Try them and you will find them prompt. Test them for integrity and you will find them candid and practical. Imitate them.

Charlottetown, P. E. I., June 17.

[We have seldom read an article that is more to the point than this one. It will bear careful reading on the part of all queen-breeders and those who have supplies of any sort to sell.

The best advertisement that any queen-breeder can put up for himself is promptness in filling orders; but no one can fill an order for a grade of queen or queens that he does not have. In that case, the only thing for him to do is to write to his customer at once, stating that he hasn't the grade called for, and ask for instructions. Very often a suggestion that he

can ship a higher or lower priced queen than was called for will meet with a ready response from the customer; but the main point is, he wants to know what to *depend* on, and he has a *right* to know. Mr. Tanton, in the article above, has given the reason *why* better than we can do it.

In a word, a queen-breeder should either fill the order promptly or send a card of explanation, telling when he can send. If a customer can not wait, he can cancel the order, and at the same time send elsewhere.

Perhaps in what we have said we may be throwing stones at our own glass house as well as that of the other fellow; but if so we will take the consequences.—ED.]

MOVING TWO CARLOADS OF BEES OVER A THOUSAND MILES

BY R. F. HOLTERMANN

Years of experience in moving bees to buckwheat as well as to favorable clover pastures and into winter quarters has given me a good deal of dearly bought information; but I have sometimes asked myself, "Is it worth while?" My friends sometimes say that I take the matter of moving bees too seriously; but my reply has always been that the only one who should undertake such work is one who looks upon this branch of beekeeping in a serious manner. Such a one must be willing to guard every point and make sure that every thing is right.

Last year I purchased a carload of bees in Michigan and brought them home with entire success. From past experience I have learned that there is a great difference between cars. For instance, some have that portion above the floor loose, so that it sways from side to side. Others have weak or uneven springs, so that while traveling they bump up and down continually, and, of course, disturb the bees unnecessarily.

On this trip I found that, in routing a car, the interests of the railway company and my own may not be the same. On this occasion, after about twenty-four hours, I was just about as far from Detroit as when I started, only on another line. If I had only known it, I could have gone by a much more direct and rapid route.

Early last winter I purchased a lot of colonies in eight and ten frame Langstroth hives from a beekeeper who lived in Missouri. The severe drouth, of last year had practically destroyed all the clover in his section, so that there was no prospect for a surplus white-honey flow.

Of several railway lines equally available we selected the one which had the reputation of being officered by men who were courteous, obliging, and desirous of considering their customers; namely, the Chicago, Milwaukee & St. Paul; and our experience proved entirely satisfactory, as we heard neither oaths nor unbecoming language from any of the railroad officials. In ordering the car I stipulated for one in good condition, and I also specified the way in which it should be sent. I had a promise from the district traffic manager that, if I would wire him ahead of my arrival, he would see that the cars were picked up at Chicago and sent on by the first through freight from that point, so we had the promise of fast freight service all through. The distance to be traveled was about six hundred miles to Chicago, and from that point home a little less than six hundred miles more. As the through freight which was to take our bees left about 9:00 P. M., we had to do most of the loading the night before, as I load only at night. This delay of nearly twenty-four hours is quite a serious matter in warm weather, when the temperature is between 80 and 90 degrees in the shade.

THE KIND OF HIVES WE HAD TO DEAL WITH.

In the lot of hives that we purchased, there were eight and ten frame hives, several odd-sized hives, and some box hives. The bees were Italians, hybrids, and blacks. Over about three-fifths of the colonies we had a shallow super on top, half of which was covered with wire screen and the rest with a thin board. Wire screen also covered the entrances.

About one-third of the hives had a portico fastened over the entrance, four inches deep and the width and height of the front of the hive. This portico had a wooden top and sides, and a wire-cloth front. Then about half way between the entrance and the top of the hive there were two air-holes, 1½ inches in diameter, in the front wall of the hive, for ventilation during swarming time. These odd-sized hives, and the box hives also, had a hole the same size at the back, which we made to enable us to keep the hives closed at the regular entrances after we brought them from the distant points in the country, the three nights previous to loading. This hole in the back was covered with wire screen the night we loaded, and it gave considerable air. The bees in hives so prepared did the best of all, but it may have been because they were blacks.

The box hives had a 1½-inch hole at the top, covered with wire screen, and the

whole hive bottom was covered with wire cloth, to which air was admitted by two-inch legs nailed to the sides of the box. It will thus be seen that we had quite a variety of hives to experiment with.

LOADING.

We decided to make sure not to reach our destination on Sunday. In the first place, I did not want to unload on Sunday, even if I could secure teams for the purpose, which was unlikely. In the second place, in hot weather it would be a serious matter to be obliged to leave the bees twenty-four hours in the car after landing—much more serious, in fact, than a similar confinement before the start.

The three nights before the night that we loaded, we spent in moving the bees in from different points in the country, as mentioned above, and on the fourth night we loaded both cars, with the exception of some thirty-five colonies, which we left until the next night, as we did not leave until 9:00, and we knew we should have time to get them in before the train pulled out.

We had engaged two 36-foot cars for the trip. Forty-foot cars are better, even if they do cost a little more; for with the former one loses much more room than the mere four feet difference in length. A 36-foot car should hold from 200 to 225 colonies in ten-frame hives fitted with shallow supers on top. We loaded the hives so as to allow a narrow passageway between the rows, the whole length of the car. The hives with top ventilation had a two-inch strip laid above them to keep the next tier of hives that distance from those below. Of course there were some exceptions to this because of the unevenness of the hives.

Strong colonies in hot weather, when they are to be confined for a considerable time, should not be packed solidly side by side, as they give off considerable heat through the hive wall—a matter of considerable importance. (The combs in the hive should run parallel with the sides of the hive.)

Those hives having front ventilation, as with the porticos, were not placed in straight rows end to end, but staggered and held apart on all sides by strips of lath in the right place. In case of upward ventilation, the hives were located more directly in line; but even then laths were used at the back to keep the bottom-board, brood-chamber, and super together and to keep the hives apart.

ON THE WAY.

As there were two of us (my son, William Ivar, and myself) we thought we could take turns at night watching the two

cars; but in this we were mistaken; for neither one of us saw the inside of the caboose. The piles of hives, although well braced each way, and securely fastened together with laths, gradually moved sidewise in the long fast trip, and we needed all the spare lath and the assortment of nails, hammer, and lantern that each car had, together with our own most careful watching, before we could call every thing safe, and then we did not dare to trust the hives alone. During the three nights on the road we had only snatches of sleep on top of a couple of bare boards or hive covers.

Our other equipment consisted of a barrel of water, a pail, and a dipper for sprinkling the bees when they rushed about their hives with their tongues sticking out through the screen. We also had cotton batting for quickly stopping any little opening that might allow bees to get out. The good wife of Mr. Diemer had provided a generous supply of lunch. One can not depend on getting meals on the way.

I have found it good policy to recognize the fact that, with a jar of honey or a little cash, a railway man may serve my interests without wronging his employer. I do not believe in trying to bribe a conductor to let one ride free. We had an understanding as to the transportation of ourselves, and in Canada the railway company, by order of the railway commission, has to give free transportation for one man with each car any way; but as the train is made up, if the car is near the center of a long line of cars the slack of the train results in a tremendous and unavoidable jar to the car. We made up train at Chicago, and again partially at Detroit; and in both instances, as well as at the starting point, we secured a place near the engine. Again, at the stop-overs the bees are likely to get restless. While traveling, the air is circulating freely, and the bees remain quiet; but if the car is at a standstill with the sun beating on one side, and perhaps a building close by to reflect it on the other, and to shut off the air, the care-taker has need to be anxious, and a dollar is nothing to pay to be put in a breezy position.

SPEED OF FAST FREIGHT TRAINS.

The run to Chicago took only about 31 hours. From that point we were transferred to the Chicago Belt Line, which took our two cars to the Wabash Line, on which the one run from there to Detroit took a little less than sixteen hours. There we made up train again and reached home about 10:00 P. M.—four days from the time we loaded the first bees, or three days from the time we started.

The temperature when we started was between 80 and 90, and the air very warm and sultry. However, the brood was uninjured; and so far as I could judge, the brood-chambers did not show any effects from the confinement. This was contrary to my expectations, and must have been due to our faithful and frequent watering. Practically no black bees or their crosses were dead; but among the strong Italian colonies we found quite a number of dead bees. I told Mr. Diemer before we left that I expected this, as I have always noticed that Italians, when excited and unable to get out of the hive, may turn and sting one another to death. However, this was not a serious loss, and the trip was a decided success. It was not long after the bees were unloaded and the hives opened that we sought a well-earned rest.

Brantford, Ontario, Canada.

BEEKEEPING AND SCHOOLTEACHING

BY B. D. ROBERTS

In view of the now inadequate wages of the country schoolteacher, and the short term of school, it becomes necessary for the great majority of pedagogues to seek summer employment. At present, it seems, farming is the chief resort of those who do not "take the road," canvassing. But farming can not be carried on successfully during vacation alone. Thus, with the capital which is necessary, and the hired help which is often insufficient, the net proceeds are greatly diminished. Again, farming is open only to the men, while a great many of our teachers are women.

To such a somewhat cultured class of men and women there is open no more gentlemanly, lucrative, and yet recreative occupation than beekeeping. It is true, attention is required in early spring; but by the proper use of Saturdays and evenings it is possible to get along till vacation.

Beekeeping offers the ideal field for exercise of the teacher's scientific and experimental tendencies, and can not but be a success when attempted with his usual energy. The small capital, the comparatively sure returns, the unlimited field and the pleasant out-of-doors work, would surely appeal to the teacher were his attention but once attracted, and yet in none of the teacher's periodicals have I seen the subject mentioned, even in an advertisement. Nor is this a one-sided proposition. Teachers, as a class, represent some of the best mental energy in our land, and, with their organization and co-operation, which would certainly be extended to their

vacation pursuits, could they once be interested, they would not be such a despicable addition to beedom. Through their joining the ranks, the honey market would not be loaded, but rather livened, for they could and would, since it would then be of personal interest to them, create a great demand for honey among the younger generation, and at the same time do their duty by expounding the truth concerning this paragon of sweetness.

Knox, Ind., Aug. 8.

BAD TASTE CAUSED BY DEAD BEES IN HONEY

BY BENJAMIN C. AUTEN

When raw fruit is put up in jars for exhibition purposes, the experts in charge of the work spend weeks testing and changing the solutions in which they are preserved, so as to get the density exactly the same as that of the enclosed juices of the fruit to be preserved. If it is too light in density, the fruit will burst; if too dense, it will shrivel. This is because, when two fluids of different densities are separated by a membrane, the two fluids interchange until the mixture each side is of the same density, the less dense fluid going through faster than the heavier one.

In an article by a prominent honey-producer, published two seasons ago, the writer did not deem it necessary, when extracting, to keep the robbing bees which fell into the vat constantly skimmed out, taking it for granted, I presume, that the bees were clean and would do no harm if taken out at the end of the day or at the close of the job. How clean bees may be is not necessary to consider. As soon as a bee is in the honey it begins to shrivel, this shriveling being due to the escape of the body fluids through the membranous walls of the insect into the honey; and, though honey is a powerful preservative, it can not prevent the occurrence of chemical changes in the animal matter (though it may prevent actual decay) which can be of no advantage to the honey as a food.

As a matter of fact, I have bought extracted honey which had a flavor almost exactly analogous to the odor which comes from decaying bees in hives in which they had frozen out. Is it not possible that here arises a part, at least, of the popular prejudice against extracted honey?

Carthage, Missouri.

[It is not always possible to prevent some bees from being in the honey, but it is surely best to skim them out several times a day, at least.—ED.]

FIG. 1.—A corner of A. B. Anthony's apiary near Sterling, Ill., showing his specially constructed hive.

THE ANTHONY "LEAF" HIVE

A Hive in which the Combs may be Thumbed over Like the Leaves of a Book, and yet Lifted out like the Loose Leaves of a Ledger, either from the Bottom or Top

BY H. H. ROOT

There are few beekeepers who, at one time or another, have not had visions of an ideal hive made according to their own notions; and manufacturers of bee supplies have had opportunities galore to buy

"patent rights" for making and selling these strange creations, destined to be of real value to no one. There are something over two thousand patents issued on hives, every one of which must have cost a hundred dollars at least; yet those that have really been of benefit to beekeepers in general can be counted probably on the fingers of one hand, without counting the thumb; therefore when we heard that Mr. A. B. Anthony, of Sterling, Ill., had invented a hive we were naturally inclined to believe

FIG. 2.—One of the hives turned over on end by means of the clamp, and the lower half of the brood-chamber with the bottom-board removed to allow the frames to swing from side to side like the leaves of a book.

FIG. 3.—If necessary, any one of the frames may be lifted out without disturbing the rest.

that his hive, while it might be the hive of hives in his own eyes, was probably lacking in practicability from one standpoint or another; but after investigation we felt that it was worthy of being placed before the beekeepers for their approval or disapproval as the case might be.

For a good many years Mr. Anthony

has felt that the great drawback to modern beekeeping is the time and labor required in going through the present type of hives. He had found there was merit in keeping down queen-cells; and if he could get at them speedily, or in any way quickly ascertain what was going on in the brood-chamber, he could not only know the sit-

FIG. 4.—The frames may be handled from the top if desired, after the cover and supers are removed.

FIG. 5.—Cover removed, showing construction of super, wide frame for the sections, with separating slats nailed on one side, etc. The peculiar construction allows room for 33 sections in one super over the eight-frame hive.

uation, but the better handle the swarming problem, and—"keep more bees."

With application to the problem for twenty-three years, Mr. Anthony finally perfected a modification of the Huber "leaf" hive in which he could turn the combs like the leaves of a book from one side to another, giving an opportunity to inspect each one thoroughly while at the same time, if occasion demanded, he could remove any comb just as easily as a leaf may be taken from the modern loose-leaf ledger. And he went still further, in that he adopted a construction that made it possible for him to remove the combs at will, either from the bottom of the brood-chamber or from the top in the regular way.

My first impression of his apiary of about one hundred colonies was that the hives had been located on insecure foundations, and that a strong wind had toppled most of them half over, where they remained, neither standing up nor lying down. On coming nearer the yard I made up my mind that Mr. Anthony had built his hives with steep floors, on the old theory that the moth-worms, however much against their will, if they fell off the combs would be unceremoniously rolled downhill out of the hive entrance. However, I discovered that some of the entrances (most of them in fact) were at the "top of the hill" rather than at the bottom. See Fig. 1, which shows a corner of the yard. Notice that the en-

trance of the hive at the extreme right is at the "bottom of the hill," while in case of the rest of the hives the bottom-board slants the other way, so that the entrances are at the top.

Take the hive in the foreground of Fig. 1 for example. Suppose one stood at the left of this hive and looked squarely at the end of it. He would manifestly observe that the end of the brood-chamber is a parallelogram, and that the corners are not right angles, as in case of the ordinary hive. Moreover, the brood-chamber case is made up of two halves, the ends of which are triangles as shown, instead of rectangles. Now, when Mr. Anthony desires to look over his brood-chamber, perhaps to find the queen, he uses a clamp somewhat similar in principle to the device described in *GLEANINGS* by F. H. Cyrenius, page 774, July 15, 1905. He quickly adjusts this clamp and tips the whole hive over without removing the cover or the super, and without disturbing the upper part of the hive at all. With the hive tipped over in this position resting on the clamp, it is the work of but a moment to remove the lower part of the brood-chamber case, to which the floor is attached, and lay it to one side as in Fig. 2. Then, without prying anything loose, the combs beginning at one side may be swung over, one by one, so that both sides are exposed. While this work is being done, there is no danger of killing

Selling strawberries; the way E. B. Rood manages near Bradentown, Florida. See page 591.

bees, nor sliding combs past each other so that bees are rolled and crushed, and thus infuriated; and, what is more noticeable, the moving of the combs is as quietly done as the turning of the leaves in a book, and the bees show no tendency to bunch up on the combs, so that, if one is looking for the queen, there is no great mass of bees collecting at any one point, which makes it difficult to see the combs at all, and almost impossible to locate the queen without using so much smoke as to cause the bees to stampede.

If desired, the bees may be brushed from both sides of every comb without taking the combs out of the hive body at all—that is, without detaching them, for there is plenty of room for the brush on either side of the combs as they are swung one by one from one side to the other.

If Mr. Anthony wishes to take a comb entirely out of the hive, he can do so more easily than he could take a comb from an ordinary hive (Fig. 3), and he can put the combs back just as easily. The combs can not be slid back and forth in the hive in bunches of twos or threes; but with this construction there is, perhaps, not as much need of it as with the ordinary hive. If one desires, the cover and supers may be removed and the combs lifted out from the top as in Fig. 4; but Mr. Anthony finds that there are so many advantages connected with the other way that he rarely gets at his combs from the top.

I found in this hive a new method for spacing brood-frames, in that they are hung off the center, causing them, through gravity, to attempt to swing beyond the perpendicular. They are prevented from doing so, however, because of pins on the lower inside ends of the brood-case against which they lean, and are spaced. This construction affords little chance for sticking with propolis, and there are no obstructions like nails and staples to dull an uncapping-knife or to hitch and catch in removing frames.

I was told more was obtained in this hive than expected; for with much manipulation of it in periods of dearth of honey, no time as yet had occasioned the use of a tent; and it looks reasonable that the keeping of brood-frames from exposure at their top sides, where the honey is stored, and the keeping of all frames compact would aid much toward the avoidance of robbing.

Mr. Anthony runs for comb honey almost exclusively. The few extracting-supers that he has are exactly like his brood-chamber. The comb-honey super is shown in Fig. 5. Instead of the regular section-holders, wide frames are used, according to the Hand method, which entirely surround the sections. The foundation is also put in by J. E. Hand's plan, in split sections. The slats forming the separators are nailed on one side of the wide frames, as shown by the frame at the left lying on top.

Owing to the fact that the top of the hive is not level, but slanting, the capacity of a ten-frame super is provided on the eight-frame hive. The construction of the wide frame and separator slats combined permit easy passage of the bees from one section to another at all points, so that one section is not divided from another by cross-cleats, thus separating the bees into small groups. The three sections are really more like one shallow extracting-frame, so far as the passage of the bees over and around them is concerned.

Notice that the super is a little longer than the hive. There is an object in this; for when the inside fixtures are removed, as in the fall, the empty supers are used as an outside winter case, three or more of them being slid down over the brood-chamber, making a tight double wall completely enclosing the hive itself, and leaving room for plenty of packing over the top of the brood-chamber.

It will be noted that one side of the super is considerably higher than the other. Instead of starting in the center, the bees always start on this upper side because it is warmer. At such times and when with cool weather there is a slow honey-flow and the super is not uniformly worked, it is the labor of but a moment to turn the super around with the other side at the top so that the bees will be sure to complete that. This accomplishes the same result as is brought about by shifting the sections from the outside to the center of an ordinary super to be completed. By

reason of fewer propolis contact points, finished frames may be removed to avoid discoloration, or empty substitutes be given when the near close of a honey-flow does not warrant the giving of a whole super.

In No. 5 the entrance is at the bottom of the brood-chamber. In a number of the other hives it is on the other side, as shown in some of the other illustrations. It is possible to have the entrance at either side, and it takes but a moment or two to change from one to the other. Mr. Anthony has been experimenting considerably with the two positions for the entrance, and has not entirely decided whether either position is best suited for all occasions; or whether one position is better at one time, and the other for some other time of the year. There are certain advantages in both; and it is probable that, at certain times of the year, one position would be preferable to the other. Of course, if the change were made the hive would be turned around, so that the entrance would always be in the same direction. Notice that the brood-frames, instead of being at right angles to the entrance, as in the ordinary hive, are parallel to it, as in the hive used by Mr. Allen Latham. The sections, moreover, are not parallel to the brood-combs, but lie crosswise. Another decided difference is that the bee-space, instead of being over the top-bars, is under the bottom-bars, so that there is no crushing of bees in case the brood-chamber or super is set down on any thing flat, helping also to

An up-to-date Wright Brothers flying-machine. The persons shown in the cut are your humble servant, A. I. Root, and Mr. Oscar Brindley, the aviator. See page 593.

A strip of buckwheat in A. I. Root's Florida home. See page 593.

keep surplus removals covered and protected from robbers, with the shifting found in all apiaries.

If more than two comb-honey supers were stacked upon the hives there would be danger that they would topple over;

but bees do scarcely any work in a comb-honey super three stories high, and, besides, such honey should be removed as soon as finished, to be nice and white. The extracting-super, instead of setting off at an angle like the comb-honey supers, stand vertical, so that any number of them can be stacked up.

The cover is a very substantial one, being made of $\frac{7}{8}$ boards halved together, so that they can come and go with the shrinking and swelling of the wood, and covered with tin painted on both sides.

It can not be denied that a hive of this pattern would enable any foul-brood inspector to make an examination very quickly; and now that disease is creeping over the country at such an astonishing rate, this feature alone would certainly be quite an advantage. But there are always some disadvantages connected with a radical departure from standard lines.

I may be wrong; but in my opinion there are two serious disadvantages. One is that such hives could not be used interchangeably with any other standard hive on the market, as the covers, bottom-boards, brood-frames, and, in fact, all the accessories are either odd-sized or odd-shaped. The second disadvantage is that these hives, owing to the greater number of parts, and the angular shapes, are not

A. I. Root's windmill, tank, and tower in Florida.

FIG. 1.—Mr. Rood's "lightning operator." The picture gives you a good glimpse of the celery when ready to be harvested.

only much more complicated and harder to put together, but more expensive. Just how much more expensive I can not say at this time. Mr. Anthony, however, says that all good things come to the front, and he thinks that progressive beekeepers with a future would be willing to pay for the added cost. The hive is fully patented, the claims covering both the design and details of construction.

SHORT CUTS FROM THE PRODUCER TO THE CONSUMER

BY A. I. ROOT

For several years past I have had quite a little to say to our readers in regard to Mr. E. B. Rood. I have told you something about how nicely he manages as superintendent of our Sunday-school on Sunday, and I have also told you quite a little about his skill in market gardening. He was one of the first to demonstrate that strawberries can be grown successfully in Manatee Co.; and now for many years he has been growing strawberries by the acre, more or less, and marketing all or nearly all in his own locality. I do not mean to say that he peddles them from house to house, but he runs them into towns every morning with his automobile, and gets them into the hands of

the people for dinner within an hour or two after they are picked from the vines. While his horses are busy plowing and cultivating in the fields, the automobile takes the berries quickly and safely to the grocer, where they are sold out and consumed, usually the very day they are picked. As I have explained, Mr. Rood also does considerable business in the way of selling real estate; and after the strawberries are unloaded he takes time to carry people who come from the North around the surrounding country, and through his own beautiful garden, straw-

FIG. 5.—A heap of boxes ready to be filled; also trimmers and packers at work.

FIG. 2.—Trimming the celery and packing it in boxes.

berries, celery, sweet and Irish potatoes, and other crops according to the season. As a matter of course, everybody does not succeed as my good neighbor Rood does; and some are so unkind as to intimate that his beautifully kept gardens are more to help him sell real estate than to make a profit on his crops; but as he is located just across the street from my own five acres, I think I have an opportunity to know something about what it costs him to keep his place in such beautiful trim and what he gets for the stuff he sells. And, by the way, it just

now occurs to me that this is the biggest kind of a chance for any of you to sell your real estate, if you happen to have more than you need, or are getting too old to take care of a farm. The best advertisement that can *possibly* be gotten up for a piece of land is to put on it a few acres, a single acre, or even a part of an acre, in "high-pressure" up-to-date gardening. The books and periodicals now devoted to rural industries will keep you posted as to the wonderful things being done along these lines in this year of 1912.

FIG. 3.—A glimpse at "short range" of the trimmed bunches ready to be packed in cases.

FIG. 4.—A glimpse of the celery rows and the stalks after cutting.

THE WRIGHT BROTHERS' FLYING MACHINE IN THE YEAR 1912. SEE P. 589

BY A. I. ROOT

Some time ago a few of the leading business men of Medina became enthusiastic over the idea of having a flying-machine exhibition on our fairground on the Fourth. Correspondence with the people who send out flying-machines brought out the fact that it would cost a good deal more money on the Fourth than later during fairtime. Indeed, the demand was so great for machines on that special day that the best arrangement our people could make would be \$1000 for a man and machine to make three trips—the man to remain in the air not less than 45 minutes all together. The question was whether our county of Medina would turn out in sufficient numbers at 25 cts. admission to make up the thousand dollars. But it transpired that something like 10,000 people were on hand to witness the flights. The flights were a perfect success in every respect. The operator handled his machine with almost the ease that a bird in the air flaps its wings. He went up something like a quarter of a mile, and went off over the country for two or three miles in different directions—executed a variety of sharp turns, dives, etc.

The machine, as you see, p. 589, is made to carry a passenger; but as it requires a longer space to get off the ground with a passenger than our fairground afforded, no attempt was made to carry a passenger. As I was close at hand, however, during all the flights and preliminaries, a request was made that I occupy the vacant seat while the machine was standing on the ground, and have a picture taken of myself and Mr. Brindley. Perhaps I should explain that the Wright Brothers manufacture the machines, but they have nothing to do with renting them out for fairtime, exhibitions, etc. All correspondence in regard to this matter should be directed to The Mercurial Aeroplane and Entertainment Co., 803 Central National Bank Building, St. Louis, Mo.

You will notice the operator has hold of two levers, besides other levers operated by the feet. As it would be inconvenient for him to take his watch out of his pocket, he has a pretty little timepiece strapped to his wrist, as you will notice.

I had a long talk with him during the day, and he entirely agrees with me in thinking that there is but little danger of loss of life if the instructions furnished by the Wright Brothers are strictly complied with. The deaths of at least a part of the

aviators have been because they became excited, and wanted to make a display that was evidently unsafe, or started out when the weather was unfavorable. Somewhere out west during a fair, I think it was, the aviator declared it was not safe to undertake the flight just then. But the crowd hooted and jeered, called him a coward, and said "the machine would not fly anyhow," etc. He was a young fellow, and finally, in desperation, he said he *would* fly, even if it broke his neck, and he did. He was killed almost instantly. That crowd was *guilty of murder*. In another case a young fellow undertook to exploit "sliding down hill on the air," at a breakneck speed, expecting to turn the machine up again when he neared the ground. This time, however, he had a heavier machine than he had ever operated before. He failed to calculate the consequences of a sudden change in direction and the momentum occasioned by the increased weight. The consequence was that the sticks of wood and wires of steel would not stand the shock. The machine was crushed, and he was killed. In one or two cases I have seen the operator smoke a cigarette before starting, to give him courage (?); but I am glad to say that Mr. Brindley, who sits by my side, never touches tobacco nor stimulants of any kind whatever. I know there is quite a mental strain on the aviator because on one occasion, owing to a little gust of wind at an inopportune moment, he failed to get off the ground. On the flight just before this, one of the wings touched a telephone wire. Had the wing been an inch or two closer to the wire the result would have been a smash-up and very likely death to the operator. Well, after this failure to get off the ground he went and lay down on a cot in the tent, and rested some fifteen or twenty minutes while his assistants got the machine back to the starting-point. God forbid that any more lives should be sacrificed through want of care, or a disposition to take risks in showing the wonderful things that this new vehicle or transporter is capable of.

SOME GLIMPSES OF OUR FLORIDA HOME SEE P. 590

BY A. I. ROOT

First, we will consider the windmill, purchased last fall of Sears, Roebuck & Co. Let me explain that, although we are in the region of artesian wells, these wells are quite expensive, and the water is not only sulphurous but hard; while the surface wells, say eight or ten feet deep, or even

less, are mostly soft water, as they are fed usually by the abundant rains, which pass very freely through the sandy soil. Some of these surface wells are only five or six feet deep, and seldom fail to furnish water, but in limited quantities. Many people have spoiled their soft-water wells by going deeper. Of course they get a more abundant flow by going lower, but the water usually becomes hard. On this account we decided to have a windmill with tank above. The well was made by putting down three pieces of sewerpipe, 24 inches in diameter, each piece being 30 inches in length, and so far we have had plenty of water that makes a suds of soap fully as good as rain water. In fact, Mrs. Root says it takes less soap with the well water than with the rain water; but this does not mean that the water is absolutely pure. It seems to contain some mineral that acts something like soda or borax, really helping the soap to dissolve and cleanse. This surface water, however, I feel sure, is not safe for drinking, although the people generally, I believe, drink it without any hesitation. I have always used rain water right from the clouds. If I could not get this I would boil well water before drinking it. I am pretty sure I am right in taking this stand, for there is quite a little typhoid fever at some seasons of the year in that region.

The windmill shown is 40 feet high, just a little above the pine trees, as you will notice. The ten-barrel tank is twenty feet from the ground. The whole apparatus, from Sears, Roebuck & Co., cost, I think, about \$85.00; but as I had a self-oiling attachment, and also an automatic arrangement to stop and start the tank when nearly full of water, the expense was a little over \$100. This latter arrangement makes the mill stop of itself when the water is within a few inches of the top of the tank. When the water is drawn off, the mill starts of its own accord, thus keeping the tank always full without supervision, but never running over. The self-oiling arrangement enables one to oil every part of the mill by simply pulling a wire; and the mill can be stopped at any time so that it will stand perfectly still. I insisted on this, because I was not willing to submit to a squealing and screeching windmill to annoy my neighbors. Wesley and myself put the tower and mill together; and with the aid of a pulley and tackle, and a couple of other colored men, we raised the tower and got it up quite easily. The anchor at each of the four corners was made of a common barrel sunk in the ground, and filled with concrete.

The bolts that hold each of the four corners go down into the ground four feet, with a plate of iron at the bottom anchored also in concrete. A pipe connected with this elevated tank goes through all of our poultry-yards, and furnishes drinking water, as I have explained. The ornamental wire fence of which you get a glimpse runs in front of our home on the street.

BUCKWHEAT IN FLORIDA.

The strip of cleared land forming a sort of lane that you see in the picture was put around our first acre in order to prevent forest fires, during a dry spell, from encroaching on our home. This buckwheat which you see grows without any fertilizer except the droppings from the poultry, and there is not very much of that. The plants in the foreground are the Japanese buckwheat; further down, the silverhull. In our Florida sand the Japanese comes up first, and was very much ahead of the silverhull all through the season.

The picture also gives you a glimpse of the way we make our fences to restrain the poultry. The lower strip is one-inch mesh and two feet wide, and goes down into the ground so as to prevent wild animals from digging under. We did not get it down quite deep enough, however, for we found holes where they got through in several places. I think that, if the netting were to go as much as six inches below the surface, there would be very little danger of animals digging under. For the protection of the fowls at night on their roost I would, however, go a little deeper, or, perhaps, better still, turn the lower edge out horizontally about six inches. You will notice the barbed wire where the inch netting and the two-inch meet. There is also a barbed-wire strip along on top of the post. This barbed wire prevents unruly cows from making their way through the netting. Down along the creek we have another barbed wire midway between the upper and lower strands.

In regard to growing buckwheat for grain as well as food for bees, the objection is that, where you get the ground sufficiently fertile to grow a crop, you can grow other things that will bring much more money than buckwheat, such as potatoes, celery, etc.

SOME GLIMPSES OF NEIGHBOR ROOD'S CELERY GROWING.

I have said so much about Mr. Rood's success with celery in past numbers that I shall need to explain only briefly the pictures.

On one of the rows you get a glimpse of the heavy paper that is now used to tie the plants up for bleaching. The colored

man in the picture ("lightning operator") is cutting off a plant just below the ground on a row where the paper covering has been removed.

The picture shows you colored men and women at work. These people go in gangs from one celery-field to another. They are well trained for the work, each one having his appointed task, so all goes along like clockwork.

By turning the pictures around, you can read the trademark on the ends of the boxes from Mr. Rood's plantation.

The material for boxes for celery, oranges, and other Florida crops, is prepared in great factories scattered all over Southern Florida. The ends of the boxes are nailed up by machinery, so that when they get on the ground all that has to be done is to nail on the thin boards so as to make a box. Here in the North I believe it is the custom to wash all celery, especially where it is grown in the muck, before packing. In Florida they say it ships very much better without wetting at all. The sandy soil shakes off so easily that there is very little left after shipment.

Permit me to say in closing that, like corn, potatoes, and almost every other crop, there are lots of fields of *poor* celery all over Florida—crops that will not sell for enough to pay the cost of growing; but I am glad to say, however, that the Florida people, like those here in the North, are, as a rule, progressive. Every year sees more and more *good* farming and less and less *poor* crops. The "boys' corn club" is doing a lot to get their fathers out of the old rut.

SHADOWS FROM THE PAST

BY D. M. MACDONALD.

"I can call shadows (or spirits) from the vasty deep," says one of Shakespeare's characters; and another replies, "But will they come?" Well, I will call up from the long gone by past a few "characters," dim and shadowy they may be, but interesting withal, and perhaps they may teach even moderns some useful and instructive lessons in bee lore.

Thomas Hill issued the first book on bees in the English language, "A Profitable Instruction on the Perfect Ordering of Bees," in 1579. It contained little from his own pen, being mostly translations from the works of ancient writers, from Aristotle and Virgil down. But it marked an epoch in bee literature. American beekeepers might note the following: "To check swarming, skilful practicers will cut

off the king's wings, as then they will not attempt to fly far abroad." "Cut out," he advises, "all corrupt combs, and, if necessary, feed bees to enable them to renew the loss." "A beekeeper should entreat his bees by a gentle manner," a good equivalent to our modern advice, "handle gently." These early hives were made much as they were in America in comparatively recent times. "Take your hives of the wood of a hollow tree or of light boards made square"—the counterpart of your bee-gums and box hives. "In all cleanliness and sweetness, bees are much delighted," reads as if quite modern. "Gilding" was a process almost equivalent to depriving bees of their surplus takes, leaving the brood-nest intact. And they used an intimidant to aid in the process: "Put under the hives some linen rags, making a *smoake*." Hill was a good judge of honey. Here is his first prize sample: "It must be very clear, of a golden colour, and of a pleasant and sweet taste, cleaving somewhat, but not stiffening or waxing hard together."

What matters it that master Hill calls the queen a king? that he tells us bees take "45 days" to hatch? that they "sit on their young like as a hen doth on her eggs?" that bees "marvellously stay and guide themselves by carrying small stones in their legs?" that "drones are imperfect bees who have lost their sting?" and many other "whimsies"? Hill had grit in him, and gave us a *book*, "a thing rare and seldom seen in the English tongue."

Edward Southern "brak the ice," as Purchas tells us—that is, he gave us the first genuine English bee book, produced from the author's own experience, for he wrote from among the bees. He was, indeed, a practical beekeeper. His advice to beginners shows this: "Goe orderly to thy bees and thou shalt finde them gentle as sheepe." He had no belief in the efficacy of "tanging" with a basin, pot, kettle, or frying-pan. Cleanliness he rigidly inculcated. He was an advocate of powerful colonies, and believed in having all "lustie and stronge." When stung, he advises, "Take a sage leafe, cabbage leafe, or a piece of dock leafe; rub it in, and the paine will soon cease."

John Levett, 1600, claims to have had an "unparalleled experience," and that he can "resolve all doubts whatsoever." He had the true beekeeper's instinct, as he considered working among his bees more a pleasure and delight than any "irksome or laboursome toyle." He writes for country people, and especially the women of the

household, who were then the active bee-keepers of the family. He loved a bee-talk as he loved nothing else, and declares, "to talk of bees to those who love them not is like music played out of time, and harsh, or a pleasant tale to the sorrowful." He joined small lots, "as when there is a great companie they generate heat better, and therefore thrive better." The chief source of honey he looked on as a thick and gummy dew made by the influence of the "starres," and falling from heaven. He believed in a "master-bee," and tells us of the "generall guard of souldiers" attending him, and also of "commanders, generals, lieutenant-generalls, marshalls, sergeant-majors, colonells, and captains." The master-bee had a sting, but more for ornament than use. He practiced driving bees. His manner of killing off these bees was a barbarous one, being no other than crushing them to death beneath a broad board.

Rev. Charles Butler (1609) was one of the princes of beedom, and his work is a classic for all time. He himself predicted that it would "travel to the most remote parts," and this has been literally fulfilled, as no work is more sought after than the scholarly "Feminine Monarchy." Purchas said of it, "Butler wrote singularly wel," and I fully indorse the statement. The very title of the book shows he was ahead of his generation. If he did not fully realize that the queen bee is the mother of the hive, he tells us plainly that young queens were begotten of old ones, and that the drones "serve for generation and for the preservation of their sweet kind." He was thus at least on the verge of comparatively modern discoveries. He used a "hood of boultering," the original of our bee-veil. He taught that the best time to manipulate is when the bees are out in the fields; and he advised handling them gently. "For cleanliness and neatness," he says, "they are a mirror to the finest dames." Further, "Among all the creatures God hath made for the use and service of man, in respect of great profit with little cost, bees are the most to be admired; for with little care which need be no hindrance to business, but, rather, a delightful recreation, they bring in a store of sweets fit for meat and medicine." Of this "quintessence of all sweetness," he has much to say. The best prize samples should be "clear, odoriferous, yellow like pale gold, sharp sweet or pleasant to the taste, and of mean consistency." All honey, however, was not like this. "Some make one work of all—pounding and compound-

ing honey, wax, bees, and works all together; then with a press they violently wring out all that will run."

In 1618 William Lawson published "Country Housewives' Garden with the Husbandry of Bees, being the Experience of 48 Years' Labour among the Bees." He counts no orchard or garden complete without some hives of bees; and no housewife is a good one "that wanteth bees and is not skilful in handling them. They yield, rightly managed, great pleasure and large profit. Stings are not to be apprehended, because they know their keeper, who ought to be familiar with them." Many use smoke in handling bees, but he utterly disliked its application. Ringing in time of swarming is a "meare fancy." Violent handling of them is "simply evill." Bees, of all creatures, love cleanliness and peace; therefore handle them leisurely and quietly and they will not hurt. A drone-trap was used; and for mice, then very troublesome, the best remedies are "cats, rats, traps, bane, and watching. Contract entrance to exclude such vermine; but do not stop up close, as bees require a flight in winter."

"The profit of bees is great." He does not give the price of honey; but it must have been high, for he asserts that forty stocks will yield more profit than forty acres of ground. The sisterhood should be interested in Lawson's work, as it was written specially for the gentle sex, and he all but asserts that a good "bee woman" must be a good housewife.

Following chronologically we next come to Richard Remnant, 1637, who insists on the "great profits" to be derived from bees. Apparently he found the pursuit a paying one, as he asserts he bought and sold to the value of a thousand pounds a year. In uniting and handling bees Remnant used smoke. He unhesitatingly sets the queen down as a female and the drone as a male. He, however, confounded pollen and wax, as most writers did long after his time. "The wax is gathered of the flowers or bloomes." Pollen was then looked on as "animable matter" from whence the bees were generated. The bees gathered it, carried into the cells, whence the king dealt with it, and it became a "maggot" out of which workers were evolved. He fed by cutting out a comb from a full hive over-supplied, and inserting it in a poor hive. "In all these operations, still the bees with smoke (but not too much). Be not fearful, but patient and gentle, and in time with experience you will become readie in all these things," which is sage advice even to-day.

Remnant's book is specially interesting because it contains the first precise reference to that fell scourge, foul brood. Here is the extract: "Some putrefaction sticks fast in the cells, and is of a brown or deepish yellow colour, which should have been brood, but came not to perfection. Other putrefaction looketh somewhat white, and was a brood, but afterwards took cold, and so was chilled, and perished before it came to maturitie." Chilled brood and foul brood!

Banff, Scotland.

MORE ABOUT THE IMPERIAL COUNTY ORDINANCE

Two Other Counties Have it in Force

BY A. F. WAGNER

As you have given Mr. J. E. Ross, of Brawley, Cal., space in your paper for his article in the July 15th number I think it no more than fair that you accord me the same privilege.

In the first place, I want to eliminate all personality. In order to enlighten the readers of GLEANINGS I will give them a brief history of the situation here.

In 1909, when I was appointed inspector of apiaries this county contained somewhere in the neighborhood of 5000 colonies of bees. Bees were being brought in from other parts of the State, without any inspection. In some cases the shipments were accompanied with a certificate where the inspector of apiaries never opened a hive. This was done in order to cover the State law, I understand.

When I explained this situation to the beekeepers a committee went before the Board of Supervisors and asked for some protection. The supervisors suggested that I might hold them up at Imperial Junction for inspection. Imperial Junction is no place to inspect bees, it being away from the water and on the barren desert. No bees were inspected there.

During the year 1911 several shipments of bees were made into this county, and through these shipments more foul brood was introduced. In September, 1911, I met Mr. Pleasants, the inspector of apiaries of Orange Co. I explained the situation briefly to him. He told me Orange Co. had an ordinance that would suit our case, and said he would send me a copy of it. I handed the Imperial Valley Beekeepers' Association one of them, not for endorsement, as Mr. Ross would have you believe, as we were not ready for that then, but for their consideration. At the close of

the meeting they appointed me a committee of one to secure signers to a petition to be presented to the Board of Supervisors. As you no doubt know, this is a large county; and for me to see every beeman and obtain his signature would take considerable time—in fact, more time than I could spare—so I sent each beeman a card, asking him to attend a meeting, stating the purpose. At this meeting the whole county was represented, and a committee of three was appointed to obtain signers to a petition to be presented to the Board of Supervisors for the enactment of this ordinance. Eighteen signed this petition at this meeting. When the petition was presented to the Board it contained 48 names. This petition is on file at the County Clerk's office now, and open for inspection. The Board passed this ordinance, and it became a law Feb. 1, 1912, and is in force now.

WHAT WERE THE RESULTS?

Upon its passage I immediately notified all the inspectors, and also general freight agent of the railroad companies. In the latter part of February a carload of bees was shipped into Imperial from Los Angeles Co. Working under Sec. 7 of said ordinance, I asked that these bees be moved to Imperial Junction, or three miles from any other yard, and be held thirty days, not to exceed sixty days, in quarantine, or to remove them from the county. I am convinced that I was fully within the bounds of the law. This was done for two reasons—first, an irregular certificate, not giving name of proper owner and date of inspection; and, second, shipped from a district where European foul brood was known to exist. Immediately a great howl was raised—not from beemen, however. All kinds of tactics were resorted to, from threats of personal injury to large suits of damage. I was determined, however, to test the ordinance on this case. Seeing that I could not be bribed nor coerced, while I was away (during the night) influence was brought to bear somehow on the supervisor of that district so that he himself took the responsibility of having the bees released, and the District Attorney asked me to work under Sec. 2 of said ordinance. Now, I am no attorney at law, and do not pretend to understand all the ordinance; but I surely think the framers of this ordinance had legal advice, as three counties now have such ordinance in force—namely, Orange, Riverside, and Imperial. I also understand several other counties have similar ordinances. So far as I know, it has never been tested in court. So far

as using it as a bluff, I will say that, out of four carloads of bees that were shipped into the county, not one case of foul brood was found.

I have the highest respect for the inspectors of apiaries of Riverside, Los Angeles, Orange, and San Diego counties; and this ordinance was not directed against them as regards the 2000 colonies kept out. I am satisfied they were not able to get a clean bill of health from the above inspectors.

I do not care to take up any more of your space; but as to Mr. Ross' accusation was merely a local affair, and I am satisfied to leave the question to the beekeepers of this county.

El Centro, Cal.

REPORT OF THE MISSOURI STATE CONVENTION

BY J. F. DIEMER, SEC.

The tenth annual convention of the Missouri State Beekeepers' Association was called to order at 4 o'clock P. M., August 1, by President J. W. Rouse, at his home in Mexico, Mo.

After prayer by the president, the usual formalities incident to such meetings were proceeded with, after which the remainder of this session was occupied with a general discussion of ways and means of increasing the membership and securing the co-operation and interest of the beekeepers of the State in the work of the association. Excellent and helpful remarks were made by J. W. Rouse; T. C. Wilson, Sec. State Board of Agriculture, Columbia, Mo.; C. P. Dadant, Pres. Illinois State Association, Hamilton, Ill.; R. A. Holekamp, St. Louis; M. E. Darby, Springfield, Mo.; W. L. Kent, and E. C. S. Miller, Mexico; E. B. Gladish, Higginsville; Irving F. Long, Marceline, Mo.; J. F. Sandker, Woodlandville, Mo., and others.

The evening session was called to order at 8 at the same place; and on motion it was ordered that articles 4 and 5 of the constitution be changed so that fifty cents should hereafter be the annual dues to the association instead of one dollar.

The matter of offering premiums at fairs for apiarian products was taken up and discussed; and it being shown by the president of the Illinois State Association that the following States offer the following amounts viz., Minnesota, \$1062; Wisconsin, \$500; Oklahoma, \$311; Illinois, \$453; Kansas, \$290; Indiana, \$248, and Missouri \$148, the secretary was instructed to investigate and find out what could be

done toward increasing the amount of premiums offered in Missouri.

On motion the secretary was instructed to take up the matter of the advisability and cost of incorporating the State Association.

On motion the secretary was instructed to cast the entire vote for the following as officers of the Association for the ensuing year: President, J. W. Rouse; Vice-president, R. A. Holekamp; Secretary-Treasurer, J. F. Diemer.

The third session was called to order at 9 o'clock on the morning of August 2, and many matters of interest were discussed, chief of which was the question as to whether our association should adopt the constitution and by-laws of the National Beekeepers' Association. Very little enthusiasm was shown for it by the members, and considerable doubt existed as to the advisability; but on final vote it was adopted.

M. E. Darby, State Inspector of Apiaries, made a report of his work. He made very emphatic the possibilities and impossibilities under the present foul-brood law, with the present limited facilities and means at his command, and convinced his hearers that it would be impossible for one man to do the work required to be done to stamp out foul brood, which exists in nearly every one of the 114 counties of the State.

At noon the convention adjourned.

How to Transfer and When

In my small apiary I have four old-time gums which I wish to replace with modern hives. What is the best way to move the bees from the old hive into the new one? As all of my bees are hybrids, I wish to get Italian queens.

Tivoli, Tex., June 26.

W. C. WIESE.

[The very best time of year to transfer is in the spring during fruit bloom, for at that time enough honey will be coming in to prevent robbing, and the bees will have a chance to build up again for their main honey-flow. Colonies can be transferred at any time of the year, although it is, of course, well to do the work early. But if a time is selected when the honey is coming in so that there will be no tendency to rob, it would be entirely feasible to do the work almost any day during the season, providing it is not cold enough to chill the brood, while the work is in progress.]

We always advise the Heddon short method of transferring bees, described in our ABC and XYZ of Bee Culture.

It is pretty late to transfer this year; but still if you are careful to select a time just before the main honey-flow is over, we believe you can transfer all right and get the bees built up in good shape for winter. The fact that your winters are not as severe as ours up here makes it possible for you to transfer almost any time during the summer. You can requenee at the same time you transfer by destroying the old queen as she runs with the rest of the bees into the new hive, which you can do very easily, as it is not at all difficult to find her as she runs in, especially if you spread a sheet in front of the hive on which to shake the bees, allowing them to run up into the new hive. After destroying the old queen you can introduce the new one by the regular cage plan described on the covers of the mailing-cages.—Ed.]

Heads of Grain from Different Fields

Answers to Questions from a Beginner

1. Are supers left on all winter?
2. If the life of a bee is eight weeks, how can they live all winter?
3. Will chickens eat bees?
4. What are bees doing around water?
5. Must all hives be fed a month before they winter? When should this begin in the vicinity of Philadelphia?
6. What is the best method for wintering bees in double-walled (Buckeye) hives?
7. Should only eight frames be left in a hive of ten frames for winter? What should be done with the remaining frames if they contain brood? Logan, Pa., July 9.

BEGINNER.

1. Supers should not be left on the hive during the winter. Comb-honey supers especially should be removed as soon as possible after the honey is capped over. With extracting supers it does not make so much difference; but they should all be removed before cold weather sets in.

2. Bees live longer than eight weeks when they are not working.

3. It has been said chickens will often eat bees, but we have never seen them. In any event we are convinced that they rarely do. A number have reported that their chickens ate drones only.

4. Bees require considerable water, especially when rearing brood; and if there is no water near the apiary an artificial watering-place should be provided. An old tub is satisfactory, although you should use a float or chips to prevent drowning.

5. It depends upon circumstances somewhat as to whether colonies need feeding in the fall; but if there is no honey-flow in the late summer to keep the queen laying so that there will be enough young bees to go into winter quarters, feeding should be resorted to. Some feed early in the fall, while others wait and feed thick syrup just before the cold weather comes on. A combination of both plans is often to be recommended.

6. It is impossible here to go into a full discussion of wintering, and we would refer you therefore to our booklet, *The Buckeye Beehive*. Make sure, however, to have good strong clusters made up of young bees largely. Also make sure that the stores are ample, and well arranged in the hive.

7. A very large colony might occupy the full ten frames; but it would be better to use a chaff division-board and only eight frames if the colony is not quite as strong as it should be. Late in the fall there is very little or no brood, and you can easily take out a couple of combs that contain no brood and the least honey to make room for it.—Ed.]

Trouble with Twin Mating Nuclei; Why do the Bees Ball their Queens?

You would oblige me greatly by giving me a little advice in connection with operating the twin nuclei. No doubt your men have found out by experience when is the best time of day to work with the little clusters. I find they are repeatedly balling the queen when opened during the afternoon; and in accordance with advice in the A B C book I made them up with bees from a black colony from another yard. These same black bees are most ferocious, and sting the hands and wrists continually. I don't use the smoker; but it is almost impossible to get along without some smoke. They won't let your hands come near the frames. Of course, as yet I haven't had the feeders in the hives, for I haven't had them. Perhaps that will keep them more content. Gloves make it almost impossible to handle such small frames well.

Are the ventilating holes supposed to be left uncovered by the tin? The bees from the other half of the hive are always poking into the next compartment, and no doubt worry the inmates—especially so with the extra strong nuclei. They spend half their time outside the entrance, bunched.

Kirk's Ferry, Que

H. H. SELWYN.

[Your difficulty, we think, is because you used a bad strain of black bees. If you had used gentle Italians or Carniolans you ought not to have had any trouble, providing you did not put too many bees in each side. We aim to put

about four ounces of bees in each side; that is, not much more than 1200 individuals. We should judge from what you write that you are putting too many bees on a side. We have no trouble, or very little, any way, from bees balling the queen, no matter what time of day they are opened.

The ventilating holes on the end covered with metal are simply to give ventilation. Ordinarily they should be kept closed, except in extremely hot weather, and always when robbers are inclined to cause trouble.

Another solution of your difficulty is that your covers do not fit tightly on top of the nuclei. If the bees can get from one side to the other you will have balling, no matter what time of day you open up the boxes of bees. We use an enamel cloth tacked to the center division board in such a way that one side or the other can be folded back and expose only the bees of the one side. Of course, it sometimes happens that the one side is queenless and the other has a laying queen, so that the bees of the queenless side will go over to the side that has a queen. You will generally find that the strength of one side or the other will vary according to whether it is queenless or has a queen that is laying.

We do not find any instructions anywhere in the A B C and X Y Z of Bee Culture recommending the use of black bees for the mating nuclei. You ought to use something that is pure stock—either pure Italians of a gentle strain or pure Carniolans that are equally gentle, or, possibly, Caucasians. The ordinary black bees or hybrids of this country are too cross for this purpose, and we should judge the black bees you refer to must be an exceptionally cross strain with some yellow blood in them; for bees that sting as you describe are not fit for twin mating nuclei. We would brimstone them, and start with a fresh lot of gentle bees; for you never can succeed with bees as cross as that.

You can operate twin mating nuclei any time of day when it is warm enough, when robbing is not allowed to get started. When there is a dearth of honey on we work them under cages.—Ed.]

A Honey-bound Brood-nest; How to Let the Bees into the Super

The brood-cells of our colony are nearly filled with honey, and it does not look as though there were enough empty ones to accommodate very many eggs. We presume this is due a good deal to the fact that the hive was without a queen for some time, and the bees have been filling all the cells in the lower section. They have not started to work at all in the super containing the small sections.

Cleveland, O.

A. O. S. ALLAN.

[The condition in the colony may work out all right, although there is danger that your brood-chamber may become honey-clogged; that is, the bees will get so in the habit of storing in the brood-combs that they will keep on and on, and the queen will be practically forced to quit laying. At the same time, the bees will refuse to enter the supers. To prevent the condition get some partially filled sections of honey, and place in the super as baits to entice the bees up. See reply to Bigelow, next page.—Ed.]

Swelling from Bee-sting

Can you tell me what will prevent swelling from a bee-sting?

Jewett, N. Y.

ROGER P. ROSE.

[About the only thing to do in the case of a sting is to remove it as soon as it is received, taking precaution not to squeeze the poison-bag at the time of doing it. The sooner it is removed, the better. If it is allowed to remain in the flesh the effects will be much more severe, because the sting will gradually work itself into the flesh until the contents of the entire poison-bag are injected into the wound. Sometimes if the affected part is placed in the mouth, and the poison sucked out, it helps somewhat, the same as is done in the case of snake-bites in the West.

As a general thing, there is not very much that can be done to allay the effects of the

sting except to keep down the local fever by the application of hot and cold water in alternation. Never rub the affected part, no matter how much it may itch or burn. If one has been stung for the first time he should remain very quiet, keeping himself as cool as possible. In any case, if one should receive very many stings he should apply the hot and cold applications, using a little salt in the water to help neutralize the effects of the active poison, and then keep very quiet. If blotches break out on the individual, call the services of a physician immediately, especially if the heart should be affected.

The foregoing advice applies only to those who have not become accustomed to the effects of the poison. Old beekeepers, while they feel the pain of a sting as much as they ever did, have no after-swelling. They do nothing except to remove the sting. Further treatment is unnecessary.—ED.]

Robbers Attacking a Nucleus

In dividing a colony for the introduction of a queen, about half the frames were taken to the new hive and stand. The queen was put in in the usual manner; but imagine my surprise when, upon opening the hive about a day later, I found it almost solidly full of robber bees, with clouds of others hovering around the hive and striving to get in. The queen was still safe within her cage. I find robbers one of the greatest obstacles to the division of a colony. No matter what method is used, the queenless half is somewhat demoralized, and not in good condition to defend itself against robbers. I shall be glad to receive any suggestions as to what should be done when such a problem arises.

HONEY-CLOGGED BROOD CHAMBER OF A QUEENLESS COLONY.

Here are the conditions: I should like to know what an experienced beekeeper would advise. A prosperous colony, at the height of the honey flow, became queenless for some unknown reason, and failed to raise another queen. All the larvae and brood developed, and the very prosperous colony then filled every cell in the ten frames with honey and sealed it over. The bees hanging around the entrance of the hive, and the ten frames of finest sealed honey, made a sight to be remembered. What would an experienced beekeeper do first, and what would he do next? How would he treat the situation, especially if he had no extractor and no extra frames on hand? I have seen many inquiries as to what to do with a poverty-stricken hive or a weak colony; but I have never seen such a perplexing problem of over-prosperity in the way of honey. In such conditions it would be useless to have introduced a new queen, because there was not a cell in which she could lay.

EDWARD F. BIGELOW.

Arcadia, Sound Beach, Ct.

[After forming nuclei during the robbing season it is very important to reduce the size of the entrances to about the space one bee can pass at a time or close with grass. A nucleus, when it is first placed on its stand, will not recover its colony spirit sometimes for 24 hours, and in this interim robbers get into the hive and overpower it. If the weather is not too hot or the nucleus too strong we usually advise closing the entrance with grass for 24 hours. The grass will wilt, and allow the bees in the hive to escape, by which time they will have recovered their colony spirit enough so they will put up a defense. As a rule nuclei should be put on their stands the night before if the entrance is left open.

In the case of the honey-clogged brood-chamber, we would have taken out three or four combs in the center, put in empty combs, and introduced a queen. A beekeeper can have no better capital than combs of sealed stores which he may use to supply colonies short of stores late in the fall, mid-winter, or the following spring. At such times it is not practicable to feed.—ED.]

Can Honey Producers do Without the Middleman?

I wish to commend Mr. Hastings' article, July 1, 1912. He says we can not do without the middleman, and in a very ingenious manner compares what the producer pays the middleman to what he would have to pay hired help to take his place if he marketed his produce himself.

Omitting a discussion of what added profit the

middleman, jobber, wholesaler, and retailer make off the producer, and the tendency of each to cheat the other, and all of them the producer, and granting that beekeepers are better informed along these lines than most other producers, I doubt whether there is one that will not agree that there should be some better way of handling our product than the present wasteful unstandardized means of disposing of a crop of honey. Mr. Hastings says we can not do without the middleman, but I think we can. The National Association has stepped out of the dark, and says it is anxious and willing to be the middleman. Now it is up to the producers to help. If we do not sow we can not reap. Let us follow Mr. Hastings' advice, and co-operate. If we do our part it will be easy for the association to do its.

Variations in Color and Disposition

Why is it that not much is heard of the Banat bee of late? I read nothing about them in any journal. Are they no good? or what is the matter? I have one colony of what I suppose to be Banats. The queen was bought as a tested one from a well-known breeder.

I have also a colony of goldens bought of a well-known breeder. I notice no difference in color between them and my regular three-banded bees. Could these bees be called golden with only three bands? They are as gentle as the Banats.

I have 25 colonies of regular Italians. Why does their temper vary so? I have some that are almost stingless, while others attack me at a distance. The queens are fine bright yellow; the bees all well marked with three bands, all reared by myself from fine blood. Is it natural for some three-banded Italians from the same breeder to vary in temper this way?

SUBSCRIBER.

[We do not know that we can point out to you the definite objection to the Banat bees. We know that they were tried quite considerably seven or eight years ago, but for some reason or another they have been largely dropped. We presume the facts are these: On testing, they probably proved to be no better in the long run than the Italians or Carniolans, so that it would only be multiplying races and making beekeeping more complex to introduce the Banats and accomplish no real good. See the report by Albin Platz just below.

There is an unfortunate lack of uniformity in the ideas which different breeders have regarding queens, especially as regards color. What some call "golden" would be called "leather-colored," probably, by others. The goldens are usually supposed to be four or five banded, although we do not know that there would be any good reason why an extra bright-yellow queen should not be called "golden," even though she had only three bands.

The question of gentleness is one concerning which no definite law can be laid down. If queens are reared from a queen mother whose workers have always been very gentle, and introduced to respective colonies, those colonies will usually be quite gentle also. On the other hand, queens reared from a queen mother whose bees are very cross are also likely to have cross workers themselves. This is not a positive rule, however, for unquestionably the drones have some effect on the disposition of the workers, so that it depends somewhat upon the drone with which a queen mates as to whether her workers will be gentle or irritable.—ED.]

Banats Not as Good Honey Gatherers

During the last few years quite a little has been said about Banats. They have also been advertised quite extensively, and numerous merits have been claimed for them. Let me give, in a few words, my experience with them.

A little over two years ago I purchased a tested Banat queen of a prominent queen-breeder, and introduced her safely to a colony of bees. The first year I had her (1911) the honey season in this locality was a complete failure; and, moreover, American foul brood was rampant. They wintered successfully, and started the year 1912 in good condition. However, as the season advanced and they started to breed rapidly, holding their own with

other colonies, I noticed that, although their hive was packed with bees, they stored very little honey. It seems they make a great demonstration about nothing, rushing in and out; flying when it is too cool for other bees to be foraging, and, in short, accomplishing very little. The queen scatters her brood over several brood-chambers, filling some frames completely, and others scarcely at all. They are extremely excitable, scampering over the frames and stampeding in great shape, and finally dropping off in bunches into the grass. To find the queen is like finding a needle in a haystack. They are poor comb-builders, often drawing out one side of a frame of foundation and neglecting the other side. However, they have one good quality. They are hardy, and winter well. That is their only redeeming feature.

Now as to results as far as honey is concerned. My best colony of Italians produced 155 lbs. of extracted honey to date. The others averaged 95 lbs., and the Banat colony gave me just 37 lbs.—a very creditable showing surely! No more of the black fellows for me. I am going to winter them, though, and requeen next season; for about all they are good for is to hold their own against any amount of cold. After all there is no strain of bees equal to good Italian stock in gentleness, ease of manipulation, and honey-storing propensities. I advise all to stick to them.

Cincinnati, Ohio.

ALBIN PLATZ.

Hive Numbers Made of Rubberoid

The best numbers for hives that I have so far found are some that I cut myself out of rubberoid roofing.

I bought a series of two-inch stencils, and, after marking the roofing, I cut the numbers out with a penknife. It was slow work, yet it paid. I have been using them for four years, and they are still as good as when first made. They would last even better if they were painted or dipped in the paint that comes with the roofing. They are black, and show up very clearly on the white hives.

BEES, WHEN THEY START THEIR OWN CELLS, MAY
SELECT LARVAE FOUR DAYS OLD.

Page 294, May 15, Dr. Miller refers to the "American" and the "natural" method of starting cells. If a hive is dequeened at any time when the bees are not preparing to swarm, what age of larvae do they pick to start their queen-cells with? When making an experiment of this kind it is necessary to keep a pretty accurate watch on the frames for about five days before dequeening. You should chart out the different combs as you find them each day, then you will be in a fair position to know the age of the younger larvae.

I was surprised to find the number of two, three, and even four day-old larvae the workers selected to produce their queens with. Naturally, the older the larvae selected, the earlier the queen emerges from her cell; so the older larvae is by far the more likely to be the coming queen of the colony.

I very much question if the youngest novice at queen production (I do not say breeding) could do, from our point of view, more harm than the bees themselves do according to the above experiment, which has been verified on three different occasions.

Will Dr. Miller be so kind as to tell us what method the Swiss use to introduce their virgin queens?

Swarthmore, Pa.

PENN G. SNYDER.

[We respectfully turn this over to Dr. Miller.—Ed.]

Swarm Accompanied by Three Virgins

Regarding the item on number of queens in a swarm, page 469, Aug. 1—here in North Vancouver we have had unsettled weather practically all summer, and consequently some swarms have been delayed. Here is an instance: Early in June I found a swarm issuing, and noted the direction it seemed to be traveling. As all my queens are clipped I expected to find the queen in front of the hive, but was disappointed; and as the bees did not return I guessed the reason—supersedure. I located the swarm in a small patch of brush, and took an empty hive to the place.

On shaking the bees on to a sheet of newspaper, and watching them marching in, I was surprised to see three queens afterward. I opened the hive and took the first queen I could find and returned her to the parent hive, first breaking down the remaining cells. Both colonies did fairly well. The queens commenced laying, and were clipped shortly after—about two weeks, I think. Is it a common occurrence for several young queens to go out with a swarm?

A VIRGIN THAT MISSED HER HIVE WHEN RETURN-
ING FROM A FLIGHT.

On returning home after half an hour's absence one summer afternoon, about 4 o'clock, I noticed some excitement among the bees of two hives, and found the probable cause in the shape of an Italian queen on the top of one of the said hives. Now, as I said, the queens of all full colonies were clipped, but I had several nuclei (for mating) in which were virgin Italians, and I found some little excitement in one of these; so, taking a chance, I picked up the young queen and put her at the entrance of this hive; thereupon she walked boldly in, and things seemed to quiet down and I found her (or any way an Italian queen) laying about a week later. I supposed the bees had accompanied her on her matrimonial trip; but why she could not have gone straight home, and why the other hives were excited, was beyond me. Perhaps you could explain.

North Vancouver, B. C.

FRED E. WHITE.

[It is not unusual to find after swarms with a number of virgin queens. We have taken over a dozen. However, such a find should not take place in a well-regulated apiary. Occasionally, however, a good beekeeper will have more bees than he can look after, with the result that he will have after swarming and a plurality of virgins to each after swarm.]

It not infrequently happens that a virgin on returning from her wedding-trip will go into the wrong hive. Sometimes she will supplant the regular queen of the hive. At other times she will be promptly balled and killed. Old queen-breeders recognize the importance of having each hive so distinct in its location that the virgin will have no difficulty in finding her own home.—ED.]

Bee-stings a Cure for Gout

I should like to relate my experience with bees as a cure for gout. I have been a great sufferer in years past from that and lumbago. One year ago last May I purchased a hive of bees for the purpose of the benefit I might receive from them by the better fertilization of my flowers and vegetables, and while handling them I was frequently stung. I was led to believe that, as I had been free from symptoms of my old complaints, I had been benefited. Last March I was getting ready for a trip to Colorado Springs and other points in the West, when I was taken with the same old symptoms of returning gout. I called my physician, and he prescribed the old remedies, when I startled him by saying that I was going out and let my bees sting me. This was Wednesday. The next day being sunny and warm, March 14, I hobbled out to my hives and removed my overshoes (for I was not able to get on my shoes) and hose, and put my foot up to the hive entrance, but they would not sting. Finally I caught three by their wings and carried them to my foot, and they did their part all right. The next day my foot was swollen very badly, but free from pain. On the following day, Saturday, March 16, I caught two more bees and let them sting me. That evening I was able to get on a pair of loose shoes, and have been on my feet ever since. I took my trip west, and had no symptoms of gout while I was gone, nor since my return. I will say I stopped taking all medicine after my first sting, and have not taken any since. I manage to be stung at least once a week to keep me in perfect health. I would not be without my bees for any thing. They are worth to me more than all the physicians for gout and lumbago.

Portland, Me., July 18.

C. M. TALBOT.

[This is quite a remarkable case. Is there any one else among our subscribers who has had a similar experience, or knows of any one else to whom bee-stings have been a cure for gout or lumbago?—ED.]

Death of Walter M. Parrish

Walter M. Parrish, a well-known beekeeper and queen-breeder of Lawrence, Kansas, died July 18 at San Bernardino, Cal., where he had gone some months previously because of failing health. Mr. Parrish was an enthusiastic beekeeper, and was exceedingly well posted upon the subject of which he was a student almost from childhood. He will be remembered as having contributed a number of articles to the bee journals. He also lectured at various times before the bee and horticultural societies of his native State. Not only was Mr. Parrish a beekeeper, but he was an ardent lover of nature in every form. He was a young man possessed of a strong character and a kind and lovable nature. His loss to the community and the beekeeping fraternity will long be felt.

Monrovia, Cal., Aug. 19.

LEVI J. RAY.

Growing Sweet Clover on Wheat Ground

Last fall I prepared 14 acres for wheat, and in December sowed nearly five bushels of white-sweet-clover seed on the field; but it was not entirely a success. However, I will have another 14 acres of wheat ground sown to white-sweet-clover (in the hull) this fall.

To begin with, the soil must be good. Here is my plan: We have 14 acres of good fallow ground plowed and harrowed nicely. Two tons per acre of raw ground limestone have been applied since the ground was plowed. Next we will apply 250 lbs. of acid phosphate per acre. The wheat will be drilled at the regular time, and five bushels of white-sweet-clover seed will be sown just before winter. We cut our sweet-clover for hay the second year of its growth. The aftermath, or second growth, is to be turned under for potatoes the year following. We gather the seed in the fall when most of it is ripe, and spread it out on the barn floor, and stir every day or two; then it will not heat, but grow finely.

We clip our sweet clover the first year in July or August to destroy weeds; but if it is clipped twice the first season it seems to be injured. If there are but few weeds it should not be clipped at all.

Lakeville, Ind.

C. A. BUNCH.

Uniting a Laying-worker Colony with the One that Stands Nearest to it

Having just read the article on laying workers, page 523, Aug. 15, I wish to say that, in my opinion, there is little use in trying to save the colony in the same hive. My method is to unite the laying-worker colony with the nearest colony after smoking both of them so that the bees fill up with honey. I leave entirely vacant for a week the stand formerly occupied by the laying-worker hive.

Like Dr. Miller I think bees count as much in one hive as in another; but if I want a colony on the vacant stand, after a week's time, I secure it by taking frames of brood and young bees from any source I see fit, letting them raise a young queen of their own if I have no other to give them.

I leave for 24 hours the laying-worker hive over the hive it was united with, then drive all the bees down into the lower hive with smoke, brushing off the few that remain. After this I use the hive that formerly contained the laying-worker colony any place where it happens to be needed.

WESLEY L. ROBERTS.

Four to Five Comb Honey Supers per Colony

On my strong hives, that did not swarm, bees are working on their fourth and fifth comb-honey supers, and the extracting colonies are three stories high, with the two top stories ready for the bee-escape.

White and sweet clover and basswood seem to have yielded tremendously during the latter part of June and the greater part of July. I have had supers of ten shallow extracting-frames, filled from two-inch foundation-starters, in about eleven days, as I kept close watch on the honey flow.

Considering the fact that I am but an amateur, and the first season that I have actually seen a queen or even the inside of a hive, I took a chance at an out-apiary which I can visit only

after working hours, getting swarms on the trees as late as dusk. I increased from 12 to 27 hives, three of which gave third swarms which I hived on eight-frame hives, as I was anxious for increase. These are doing well. At the last inspection there was brood in seven or eight frames.

TIMOTHY O'DONNELL, JR.

Chicago, Ill., Aug. 20.

[This is a good report for a beginner; but it should be remembered that a small apiary in a comparatively isolated location will give a much larger yield in proportion to the number of colonies than a large apiary.—ED.]

Moving Bees in Hives that were About to Fall Apart

Last spring we moved some colonies in old-fashioned hives that were so old they could hardly be lifted without coming apart. In the evening, when we loaded the colonies, we ripped open a lot of burlap sacks, put about eight inches of straw in the wagon, and drove to the apiary. We tied one sack over the top of the hive; then, while one man lifted the hive up, two more tied another sack around the under part. By being careful in handling the hives we reached our destination, a distance of about six miles, and lost very few bees.

Cochranville, Pa.

FLOYD MINICK.

[It is our opinion that bees in these hives could have been moved without the use of sacking by giving them a liberal dose of smoke before loading them on the wagon, then starting off on a brisk trot. The jarring would have kept the bees god-natured; and if they were unloaded immediately before recovering their colony spirit, there probably would have been no trouble to man or horses.—ED.]

Swarm Stopped by Smoke

About a month ago I opened a colony of bees, and they started to swarm. I gave them a good smoking and they returned at once. Yesterday I had a colony start to swarm, and I gave the bees a good smoking and they returned.

Dry Fork, W. Va., Aug. 22.

E. C. MERSING.

[As a general thing, when smoke is used liberally to drive back a swarm that is coming out it has very little effect. We have tried it repeatedly; and while it may check for a moment the onslaught of bees coming out, they will recover themselves and rush harder than ever. Your experience, we should say, was quite unusual. The only way we succeed in stopping such a swarm is to clap a wire-cloth cage right over the hive, and catch the swarm in the top of the cage.—ED.]

Lizards Eating Bees

The worst enemy that my bees have are the lizards that lie under the hive and catch the heavily laden bees that miss the alighting-board. I have an extension board $5\frac{1}{2}$ inches wide; but many bees miss it and fall to the ground, especially on windy days. My hives are on stands a foot above the ground because of ants, lizards, etc., and also in order to provide ventilation underneath, for the sand is very hot during the summer months. I have found hens' eggs in which the whites were cooked by the sun and hot sand. There are a good many ants' nests under the hives on the ground. About all I can do is to use a 22-caliber rifle to kill the lizards.

Bishop, Cal.

GEO. HUNTINGTON.

Nearly One Thousand Colonies in One Apiary

I moved 700 colonies here. This is a mesquite location. I secured 350 cases of honey, and increased the apiary to 985 colonies. I now intend to move back to Chandler for alfalfa.

Chandler, Ariz.

J. M. HERMAN.

[So far as we know this is the largest apiary, possibly, in the world. Mr. Alexander kept 750 colonies in one apiary on the average; but here is a case where, for a time at least, there were nearly one thousand colonies. Can anybody beat it?—ED.]

Our Homes

A. I. ROOT.

Judge not, that ye be not judged.—MATT. 7:1.
Thou shalt not bear false witness against thy neighbor.—EX. 20:16.

And Abram said unto Lot, Let there be no strife, I pray thee, between thee and me, and between thy herdmen and my herdmen; for we be brethren.—GEN. 13:8.

In the *Rural New-Yorker* for Aug. 24, the "Hope Farm" man (friend Collinwood) has something to say in regard to "grain smut," which, in consequence of the recent rains, is unusually bad this season. And he goes over briefly the best methods up to date to counteract smut and other fungous growth. After what he says about the care of our crops in this line he gives us the following:

HUMAN SMUTS.

A political campaign is not unlike a thrashing-machine. Men and what they say are run through it, and usually you will find a black dust of abuse and falsehood rising from it. This is what I call human smut—the meanest and most dangerous part of politics. For example, I received a note from a very well-known man in Ohio, who said:

"Mr. Roosevelt came through Ohio speaking against Mr. Taft. At one place he was so drunk that three men were needed to hold him up while he talked."

When I demanded proof it seems that this man got the story from a minister, who got it from another man, who in turn got it from "three reputable persons." Another man claimed that when Roosevelt spoke in Boston he was so drunk that he staggered as he came on the platform! Another man, who sat on the stage, insists that Mr. Roosevelt caught his foot on a hanging board.

Now I call these things human smut—a germ disease which gets into the minds of some men and makes them magnify and repeat such hideous stories. Every one knows where I stand on the rum question. We have no more use for intoxicating liquor than we have for typhoid germs, and the sooner people know it the better I am satisfied. The worst criticism I have of many Prohibitionists is their narrow and malignant personal abuse of public men. Somehow they can not see how this restricts their influence. As a case of typical human smut there was a young minister accused of beating his wife! The scandal terminated in a secret trial by the elders and deacons. The case against him was as follows: Three reputable church members were in front of the minister's house one night when they heard a fearful scream. The shadows on the curtain were very distinct. They recognized the woman's voice screaming and pleading, and saw the minister striking at her with a club, and heard language "unfit for the pulpit." Then suddenly all was dark, and there was a louder scream from the woman! A complete case, you will say, and human smut flew through that town like that from an oat-thresher!

Finally some one thought that, as a matter of form, they should give the minister a chance. His story was that he and his wife were having a particularly loving time—as much so as was possible in that moldy old parsonage. All at once a mouse ran out of his hole—across the floor. Ministers' wives are very human, and this one screamed and jumped on a chair, where she stood waving her skirts and her voice to frighten the mouse. Most ministers are also human until they enter the pulpit, and this one caught up a boot-jack and ran about striking at the mouse, and, as he frankly admitted, using certain words which, while seemingly appropriate in a mouse hunt, were not for publication. The mouse got away without damage, but the bootjack knocked the lamp off the table and put it out. Thus the screams, the language, and the blows were all genuine; but the witnesses did not read the shadow

panoptime correctly. Murder was intended, but it was mouse rather than wife.

Now, human smut is scandal, and it can take such a case as this and spread a social disease which means ruin to reputation and blight upon progress. To the point—I believe these stories about Mr. Roosevelt are false and foolish. Men who are upon the most intimate terms with him tell me frankly that these stories are false. I believe them to be what I call human smut. They and the people who repeat them and add to them ought to be soaked in formalin and then sprayed with lime-sulphur. Mr. Roosevelt is at a disadvantage in that he can not say at once that he does not drink at all. I wish he could and would say so; but the men who are gathering back of him by the hundred thousand have been so well soaked with a desire to help their country that they are immune to human smut! You may take it from me that, sooner or later, the new party will be obliged to take a strong stand on the liquor question. They were forced to take up votes for women, though many of the leaders have opposed such a change. They will have to drink cold water yet.

I was exceedingly glad to see the above—so glad, in fact, that I have given place to it here in GLEANINGS. With the *Rural* I heartily agree that Mr. Roosevelt is at a disadvantage because he can not stand up as Taft recently did and say that he does not drink at all; and I think that President Taft added that any man who occupies so high and sacred a position as that of the chief executive of the United States should be able to say under all circumstances, "I do not drink."

Now, with this in mind I wish to express myself a little more freely than ever I have before in these pages in regard to the attitude of the Prohibition party toward the Anti-saloon League. Let me make another extract here from a letter from a good friend of mine who is an active Prohibitionist, and who occupies an important position in the affairs of the great city of Philadelphia. In his personal letter to me I find the following:

I am writing you a personal letter simply to enlighten you on some facts that I learned while attending the national Prohibition convention at Atlantic City last week. . . . I learned from a good ministerial brother who attended the national convention that both local option and the Anti-saloon League were positively enemies of the prohibition movement; and from very good data which were furnished me the Anti-saloon League was started by some liquor men in order to defeat the prohibition movement.

Philadelphia, July 26.

The above statement was to me simply appalling, and I can think of only one parallel case just now. When Jesus commenced doing his great work of casting out devils the Pharisees said, "This fellow doth not cast out devils but by Beelzebub the prince of devils."

Just think of it, friends. At the first meeting ever held in starting the Anti-saloon League, your old friend A. I. Root was present. Dr. Howard H. Russell, who

was an intimate friend and classmate with Ernest at Oberlin College—a most devoted Christian man and minister—was the man who first suggested the idea of combining all the people who love temperance, no matter what their affiliation, and fighting the saloon. It was my privilege to subscribe \$500 in order to start this new movement. Mr. Metcalf, a most devoted Christian man, gave another \$500; and the idea that Dr. Russell and your old friend A. I. Root were in the power of the liquor interests, or that the liquor power was back of them, is about the most absurd and silly falsehood I ever heard. Let me explain a little further.

Almost as soon as the Anti-saloon League got to doing effective work here in Ohio, the Prohibition papers, instead of bidding it Godspeed, commenced finding fault and picking flaws. I remonstrated first with the *New Voice*, and begged them to show at least Christian courtesy. The *New Voice* went down, for some reason unknown to me. The *National Prohibitionist* took its place (or at least so far as I know, it did), and began fighting the Anti-saloon League. I remonstrated again, and had a lengthy correspondence with Editor Ferguson. The *American Issue* at first made some reply to their thrusts; but I begged both periodicals for God's sake to refrain from this "cross-firing" when we were both working honestly before God, for the banishment of the saloon and for State-wide prohibition. I finally told Mr. Ferguson that his periodical would go down as did the *New Voice* if he persisted in giving place to such unchristianlike editorials or articles. Now, to show you that I was not hoping they would fail financially, or any thing of that sort, let me tell you that I gave them \$50.00 at one time when they were in financial straits, and voted repeatedly the Prohibition ticket. I was also a life subscriber to the *National Prohibitionist*; but it went down as I predicted, because, as I still think, of its unchristianlike attitude toward good temperance men who did not see things as they did. As an illustration, the pastor of our church—a man who occupied a high place in the affairs of the nation, absolutely refused to read it any further. When the *American Advance* and the *Vindicator* took the place of the *National Prohibitionist* I was pained beyond measure to see that they also—at least occasionally—gave place to articles that would almost seem as if they hated the Anti-saloon League as much as they hated the saloon-keepers.*

Because the Anti-saloon League made a map of the State of Ohio, showing the number of dry counties, the *American Advance* said it was not true, and that the counties they claimed to be dry were not dry, accusing the Anti-saloon League of untruth, and finally concluding something to the effect that the Anti-saloon League had never done any thing for temperance.*

Of course, there was some truth in some of their statements, as there always is; but it was not the whole truth. When we had our recent vote in Florida for State-wide prohibition the Anti-saloon League dropped local option entirely and worked against it; but a lot of the liquor men of Jacksonville all at once discovered that they were in hearty accord with local option. You can readily see how this came about. The Anti-saloon League came out into the open promptly, and declared they had nothing to do with them, and would have nothing to do with them. The same thing happened up in Maine. A great lot of brewers and liquor-dealers all at once discovered (as in Florida) that local option was exactly the thing; and I regret to say—in fact, I say it with pain—President Taft, together with the Governor of Maine, all at once espoused local option. Let me add that the Anti-saloon League of Ohio

agree with the Prohibition brethren. Where one county is made dry and the adjoining one is wet, the people do run over into that neighboring county. Our own county (Medina) has been dry for over 25 years; but some seven miles away, on the county line, is a little four corners where there is a saloon just over in Lorain Co. On a recent occasion eight drunks were arrested in one Sunday night round about that same saloon; and just a few nights afterward a railroad man was killed right in that vicinity, with a bottle of whisky in his pocket. I consulted our attorney to know if Medina people could do any thing to make that saloon-keeper at least obey the law; but the lawyer said the responsibility rested almost if not entirely on the authorities of Lorain Co. Notwithstanding this, I do know that the Anti-saloon League has accomplished wonderful results in making the greater part of the area of Ohio dry. We are in fact almost ready to drop local option and unite on State-wide prohibition.

Just one thing more: Many of the dry counties in Ohio have been humbugged by getting wet sympathizers into office. You will excuse me if I say that it seems as if "the very Devil himself" was shrewdly engineering for the brewers and distillers. But may the Lord be praised for the promise in his holy word, where John tells us he saw an angel come down from heaven, and he bound the old serpent, the Devil, and Satan, for a thousand years.

* While speaking about temperance periodicals, I wish to hold up to view the *Union Signal*, the official organ of the W. C. T. U. May God be praised for such a pure Christianlike periodical. Not only the love but the broad charity of the Lord Jesus Christ seems to shine forth from every page; and it has never, so far as I know, permitted a word of criticism in its pages of the Anti-saloon League; but it has again and again rejoiced in the victories they have helped to win. It also truthfully chronicles the progress and success of State-wide prohibition throughout our land; and when the mothers as well as the fathers are permitted to vote in this land of ours, I am sure a great victory will be close at hand.

* There are several points on which I heartily

will drop local option in a minute, *any where*, and vote for State-wide prohibition with the Prohibition party just as soon as there is a reasonable prospect of success. Well, now at just this very minute is the "golden opportunity." The Anti-saloon League will gladly unite with the Prohibition party and put in Chafin or Bryan as President, and thus unite the different forces, the Christian people, and the churches of *the whole United States* if the Prohibition party will consent. But instead of that they keep on hurling clubs at the Anti-saloon League, and promulgating statements at their great conventions, such as the one I have recently mentioned, held at Atlantic City. May God help us in this crisis; and may we who love righteousness and hate iniquity take *greater* care than ever before that the arch prince of darkness does not any longer get into our conventions, into our temperance periodicals, nor into our churches, and stir up strife where there is certainly no occasion nor need of strife and disagreement. Let us remember the beautiful sentiment expressed by the patriarch Abram when he said to Lot, "Let there be no strife, I pray thee, between thee and me. . . for we be brethren."

YE ARE OF MORE VALUE THAN MANY SPARROWS.

A good friend away off in Colorado sends us a little story clipped from a pamphlet sent out by the Y. M. C. A. of Mesa Co., Col. On some accounts the story belongs to "high-pressure gardening;" but in reality it should have a place in the highest kind of gardening—even the gardening that was taught by the hand and voice of God in the garden of Eden, away back in the beginning—a gardening and *garnering* of the souls belonging to the boys and girls in our homes. Here is the story. Read it and see what you think of it.

STORY OF A MESA COUNTY BOY AND A BIG RED APPLE.

John Average Mann was a successful fruit-grower in Mesa County, Colo., and Frank was his son. Frank was a bright boy and full of promise. At twelve years of age he dropped out of Sunday-school (but this was unnoticed, for in that county only 46 per cent of the boys attend Sunday-school). Shortly after this he began to smoke cigarettes which he bought at the corner grocery, contrary to the laws of that State. A few of the neighbors who chanced to know about it said something ought to be done, but nothing was. When he was fourteen he dropped out of school and folks all remarked it was "too bad." And then he began to find evil companions who led him gradually into places of ill repute, for, as the boys said, there was no other place to go. Many were sympathetic, and said something ought to be done for the boy. At seventeen Frank got in a "scrape" in Grand Junction, and it cost John several hundred dollars to save him from prison. A wise old man remarked that if John had half as much knowledge about the rearing of children as

about the growing of apples Frank would be different. Frank has since gone out into the world unprepared physically, educationally, socially, or morally to do a man's work in the world. John seldom hears from him; but last report said he was in Denver "workin' round at whatever he kin find to do." John and his lonely wife continue to work in the fruit, and dream of the happy days when Frank was a boy.

One day there was a knock at the door. It was the county horticulturist, who said he had discovered a strange blight in one of John's trees. A big red apple was withered and disfigured by some unknown disease. The field horticulturist must be called at once. In less than two hours he arrived on a motorcycle. The apple was treated, and the tree sprayed, but without avail. A "bugologist" was called from the agricultural college by telephone; the neighbors gathered, and there was a consultation, spraying, and pruning. The apple, once red and plump, now faded and withered, fell to the ground with a dead, sickening thud. The experts could not understand it, and the neighbors were frightened lest the disease might spread. A telegram was sent collect to the Department of Agriculture at Washington. In three days a great national entomologist arrived, and there was more consultation, spraying, and pruning. The disease was checked. John was grateful, and willing to pay the expense; but the county horticulturist said, "No, the people of the county are interested in the fruit crop, and they pay the bill." The field horticulturist said, "You owe me nothing. The State pays for such work." The Washington expert said, "That is what the Department of Agriculture is for. Feel free to call on us." One evening, after a few months, as John sat in his easy chair, thinking of Frank, his good wife handed him a book that had come in the day's mail. It was a bulletin of the Department of Agriculture entitled "Fighting the Heterocerous Lepidoper Bark Louse in Mesa County, Colorado." The old man sighed and said, "It is strange so many were interested in saving my apples and no one interested in saving my boy."

The above may be slightly exaggerated, especially some of the closing sentences; but I am afraid it is a fact that the different departments at Washington, especially the Department of Agriculture, seem to think this matter of preventing the dissemination of noxious insects is of more importance than looking after the morals of the children of our great land. Somebody said not long ago that the Department at Washington would send a learned professor across the continent to doctor a *sick pig*; but a sick *man*, woman, or child seemed to be outside of their jurisdiction. Let us thank God, however, that at least *something* is being done in caring for the spiritual health of our people. Now let us all work and pray that not only the Department of Agriculture (at the head of our nation) may give *more* time and attention to the spiritual life as well as the physical, but that Uncle Samuel may very soon also give us a couple of bulletins to which I should like to furnish the headings. The first would be, "A Bulletin Considering the Effect of Intoxicating Liquors on the Financial, Physical, and Spiritual Well-being of Our People." The other bulletin would be just like the above, substituting the word "tobacco" for spirituous liquors. Will you not work and pray, with me, that the above *may* be brought about?

High-pressure Gardening

EARLY POTATOES; ANOTHER "GREAT DISCOVERY."

Perhaps most of you remember how I urged you all last spring to plant just a few early potatoes in your back yard. Well, when I got back here to Ohio I undertook to "practice" what I had been "preaching," but could not find any Early Ohio, Bliss Triumph, nor any other extra early potato at any price. The best I could do was to get a bushel of Early Rose; but these had to be shipped from up in Michigan. I tell you this so that you may take warning and lay in a stock of early seed potatoes this fall, so you will not be caught as thousands of others were when they were ready to plant. Well, I planted my Early Rose, giving them the best soil and the best cultivation on nicely drained ground, and in response to my "high-pressure" treatment they just grew and grew; and now, with the abundant rains we have been having, some of the vines will reach up higher than my head, and they are still growing as thriftily and with as rank a luxuriance as when I first planted them. There are not very many potatoes yet, and Mrs. Root says they are all "going to vines," although I have assured her that wherever there were rank vines there *would* be potatoes sooner or later. Well, the result is that, while our potatoes are "Rose" all right, they do not seem to turn out to be *Early* Rose. There is no very brilliant discovery in that, is there? Right adjoining my patch my son-in-law has a garden, and he got hold of some State of Maine—the best he could do for extra earlies. Now, while my Early Rose potatoes were covering the ground with rank luxuriant foliage, the State of Maine was puffing up the ground, indicating that there were potatoes there; but as the State of Maine was still rather green and luxuriant, we hated to dig them a whole hill at a time; so we commenced "scrabbling" out the big potatoes, leaving the hill to keep on growing more.* Well, one of my favor-

ite implements, both in the greenhouse and out in the open ground, has been a good-sized kitchen spoon. This kitchen spoon, however, is made of metal, and hence it is apt to become rusty, especially if it is not cleaned off thoroughly with the fingers every time it is laid down. One day when I was in a hardware store I caught sight of a big enameled spoon, and decided that it would be just the thing to use in the garden. Well, my wonderful discovery is this: Take such a spoon as I have described, and a little basket. (I always carry a *little* basket because a big one is apt to give me "that tired feeling.") Now with your basket and spoon go through your potato-patch and find where the ground is cracked open and is puffed up. Scrape off the dirt with your spoon until you get sight of the potato that is pushing up the ground. Now slide your spoon under this potato, push down on the handle, and out pops the tuber. Put the dirt back, and go on until you have enough potatoes for dinner; and do this, if you can, just before dinner time. If you have never tried cooking potatoes right fresh from the ground, I think you will pronounce this the nicest potato you ever tasted—that is, if you have a State of Maine, Early Puritan, a Thoroughbred, or a Bliss Triumph. Put the dirt back carefully, and your vines will keep right on growing—that is, if you have plenty of moisture. Pulling out the big potatoes acts like thinning out the fruit on an apple or peach tree. It enables the others to grow larger, and it loosens up the soil, and this does good and not harm.

Now, you people who have been digging out a whole hill while the vines were green and thrifty have been losing perhaps half the crop. Do not dig potatoes, if you can help it, until the vines are all dead and dry. So long as there is any green in the stalks, the sap is gradually going down into the tubers under ground. Some of you may say that scrabbling potatoes out of a hill is nothing new; but my discovery is along the line with which it can be done with a *big enameled spoon*. You can get such a spoon of Sears, Roebuck & Co., for a nickel.

THE TRUTH ABOUT SWEET CLOVER.

Just about two years ago our booklet on sweet clover of almost 100 pages was sent out. We printed 20,000; and judging from former experience we thought they would last five or six years; but just now our printers inform me

* Does somebody ask if it is the regular habit of the author of the Home papers to wander off into a garden belonging to a neighbor and help himself whenever said neighbor happens to have better "garden sass" than his own? My reply is, this garden patch belonged to Blue Eyes, and I had been spending considerable time in pulling great weeds out of the potato-hills that nobody seemed to see but myself. One day in pulling up a great red-top weed a big nice potato came along with it; and as I went by her door I called out, "Con, I have pulled pretty near a wagonload (?) of great weeds out of your potatoes, and I am going to take along some of the tubers for pay." She replied, "All right, father; help yourself." So you may know that I not only enjoyed thus digging out the big potatoes, but I enjoyed doing it with a clear conscience; and Mrs. Root and I also enjoyed admiring the good qualities of the tubers at dinner time.

that the books are all gone but two or three hundred; and at the rate they are now called for they will all be gone before we can get another edition printed. What do you suppose is the reason? Simply this: The whole wide world is just waking up to the fact that the plant that many of us stupidly called a "noxious weed" has proved to be not only a valuable legume, but possibly the most valuable, all things considered, not even excepting alfalfa. The particular reason why it was called a noxious weed is because it is somewhat bitter in taste, with a peculiar odor. Domestic animals have to acquire the habit before they recognize it as a great nourishing food. Another thing, we have been blundering in the dark in our attempts to grow it as we grow other clovers. The recent discovery that it wants *lime*, and *must* have it, to produce the best results, has given it a great boom. We have been buying and selling the seed by the carload; but at the present time, Sept. 1, we are running short of a supply again.

A few days ago I visited Mr. H. T. Lane, of Twinsburg, O. Friend Lane is a sweet-clover crank. In fact, he told me he had invested over \$150 in hard cash during the last year for sweet-clover seed. He has been sowing it in different ways, and in different fields of something near 20 acres, although he has not secured a real good stand on much more than half that area. For instance, where it grew with tremendous luxuriance when sown with a field of barley on a low mucky soil, on a high gravelly hill it did not seem to do much if any thing unless he used either lime or a dressing of stable manure. A load or two of stable manure on a dry hilly knoll gave a luxuriant growth—some of it seven to eight and even nine feet high. Well, a good dressing of lime did almost as well as the stable manure. But when you have both lime and stable manure, then you have the ideal conditions for a stand of sweet clover. Where neither lime nor stable manure was used in many spots of ground there was no sweet clover, and almost *nothing else* for that matter, except a few stunted weeds. Mr. Lane agreed with me that he has been using too heavy a seeding. For instance, friend Wing, one of our best authorities, recommends 20 lbs. to the acre. Now, if every seed should grow, or even half of them, and the ground was limed or manured, 5 lbs. would be ample; and if you could have a stand of sweet clover with one stalk on every square foot, and soil that suits the legume, this one plant would probably give us more seed and

feed than any heavier seeding. See what is said elsewhere about transplanting alfalfa, page 568, Sept. 1.

Mr. Lane has toward a hundred colonies of bees; therefore the 20 acres of sweet clover do not make much of a show for each colony, although it keeps them raising brood, and helps to fill up with winter stores. As yet he has not got very much back for his investment of \$150. He said he had fed out a small stack of sweet clover mixed with some other grasses, and he added that his horses and cattle eat it with avidity, but he could not as yet decide how much it is worth for hay compared with other clovers. As he has quite a crop of sweet-clover seed to harvest, he will get some money for that, aside from the honey and the feed for his cattle. Perhaps I might add that friend Lane is in the great sugar belt of Northeastern Ohio. He has some of the finest maple trees I ever saw anywhere; and as he has toward a thousand sap-buckets he must have 500 or more sugar maples in his camp. He has a story to tell in regard to one of his finest and largest maple trees. It is a good match for my colony of Italians that gathered a *barrel of honey* during one summer. Well, this maple tree was tapped on three sides, each side having a six-gallon pail. During his best sugar day, in one of his best seasons, that tree filled all three of those six-gallon pails in one day. Now, if the sap continued to run all night, as it often does, that tree must have given a barrel of nice sap in 24 hours. I asked him if he had any syrup or sugar left. He said it was all sold at a good price. You see this great grove of maples is *also* a valuable adjunct to the bees. The trees must furnish a large amount of honey and pollen when in full bloom. His good mother, who still keeps house for him, is 83 years old; and she told me she was still reading my department in GLEANINGS, and expected to continue to read it with interest as long as we both live. I believe she still keeps house for her son without any assistance from any of the younger folks; and she is certainly very bright and active for a woman of her age.

PLANTING BASSWOOD TREES FOR HONEY, ETC.

In a late issue of your magazine I note what you say about your great yield of basswood. Having in mind a few acres of land which I could purchase, I beg leave to ask a few questions.

Would you consider soil lying on the western side of a low ridge or mountain a suitable place for basswood? The soil is of a sandy nature, and, I would say, below the average in fertility.

Do you mean to say in your editorial that basswood trees must be 40 years old before they yield nectar? At what age do they begin to blossom and yield? Do you know of any government bulletins on basswood trees?

Henrietta, Pa., Aug. 10. V. ROSS NICODEMUS.

My good friend, basswood trees will begin to bloom, usually, in four or five years from the seed—sometimes even three years; but, like all other plants, or at least like almost all others, it is only occasionally that we get a great yield of honey. There is as yet, I am pretty sure, no government bulletin in regard to basswood trees.

I can not answer your question about suitable soil, further than to say that bass-

wood thrives best near a stream of running water. In fact, we often see great trees overhanging water, and it does best on any low and rather moist land. But there must be drainage, for the basswood will not grow in standing water. Wherever you find it growing wild in the woods it is pretty sure to thrive under cultivation. In fact, with proper care, drainage, moisture, etc., it can be made to grow almost anywhere.

Poultry Department

THE CONVERGENT EGG-FARM, ETC.

Mr. Root.—Please tell us in your paper whether Mr. Stoddard ever in his life made a *living* from poultry. I have known of him 30 years, and he was always advocating some wonderful (Philo) scheme for making people rich raising poultry. But they were all wind, and impractical nonsense. He is still at it.

Great Barrington, Mass.

SETH WINSTONE.

My good friend, are you not a little rough on our old friend Stoddard? While there is a good deal of truth in what you say, I believe it is also true that Stoddard's first little book, "An Egg-farm," in which he first, so far as I know, advocated colony houses, was a very valuable contribution to our poultry literature. If you have been a reader of GLEANINGS you may be aware that I afterward severely criticised his larger book because it had so much impractical machinery.

Now, in regard to the convergent-poultry-yards idea: A few days ago I visited the city of Cleveland expressly to get a competent architect to make plans for our proposed bungalow cottage. He said it was out of the question for him to do it at once as I desired, and he finally gave his reasons. He and all his force of several clerks were working almost day and night on a great dairy barn or dairy farm. It was exactly like the convergent poultry-yard that I described in GLEANINGS. The cows were all on a circle with their heads toward the center, and the care was all given from that inner circle, the feed being dropped by gravity from the loft overhead. The architect, Mr. Herbert B. Briggs, informed us that such a dairy farm is already in working order at the Agricultural University of Illinois. Now, friend Stoddard in his youth did give us a good idea through the *American Agriculturist*, and later in his 30-cent book, of which we sold over 1000 copies; and if he gives us *in his old age* another good idea, in the convergent yard, shall we not give him credit? Very likely it is true that friend Stoddard, like many other inventors and geniuses, never had the faculty for "making money,"

as does friend Philo to whom you allude, and others who may not be half as deserving.

"MORAL DEGENERATES" IN THE CHICKEN-YARD.

In your issue for Aug. 15 you ask, "Will chickens eat bees?" I take the usual amateur's delight in volunteering what I *know* to be a fact. Not all chickens will. I don't believe some could even be induced to eat even dead ones; but you know, or ought to, that in every poultry-yard there is apt to be one or more "moral degenerates" that will persist in eating unwholesome food, catching wasps, centipedes, etc., and any filthy offal they can get to.

For two years I had chickens and bees. The first year I had two that just haunted the runway before the hives till I killed them. The second year I had one that took it up, so I made away with him. They were fair-sized broilers before I ever caught them at it. They may have begun by picking up dead bees around the entrances, though I frequently poured crude petroleum over them and all around the hives to keep down ants and grass.

They didn't seem to mind being stung. I would throw cobs at the hives to stir the bees up, hoping they would rally and drive them off. They would just dance and flutter a little, and then pick off the adhering bees and eat them, and deliberately go back to picking them off the alighting-board.

I have seen a hen pick them off the alighting-board of a hive in an old negro's front yard. He said she ate a few every day "for pepper."

A bee-sting hurts a little chick, and swells it up as tight as a tick. I had one killed by one stinging on the neck.

Bee-eaters are like egg-eaters, feather-pullers, and those that get to pecking each other's heads to pieces. Feeding meat scrap is sometimes supposed to induce these habits; by others, the absence of meat in the rations is charged to the fault; but it is just a depraved appetite that will show up in some individuals of every flock, whatever the plan of management.

Little Rock, Ark., Aug. 1. JERRY HUMPHREY.

My experience indicates that the above is exactly right.

Here is something more along the same line:

Chickens will eat bees when they have no large run. I was trying out a pen of White Leghorns for record, and *confined* them near where bees would fly out in early spring and get chilled, and others would fly near by. The chickens would catch them first, kill them, and then eat them. I lost many before I "got wise." I have been keeping bees about 20 years.

Astoria, N. Y.

C. L.

You want to know if any one has positive knowledge about chickens eating bees. I will say this: I noticed a young chicken, probably a third grown, eating bees at the entrance as they would alight. I killed the chicken, and it had killed ninety, I think. This is the only one which I ever had occasion to examine.

HONEY-CROP CONDITIONS.

By consulting our Honey Column it would appear from the reports that the market in some localities is a little quiet, owing to the heavy arrivals of fruit; but the demand will undoubtedly pick up. In some places the arrivals of honey are slow in coming in. The demand for comb honey is active in most places, while in nearly all of them the market for extracted is stationary or a little slow. As we reported in our last issue, the crop of buckwheat honey will be light. It is apparent also that in some sections of the West, the honey season is below average, particularly on the western slope of the Rockies.

THE FRED W. MUTH CO. BURNED OUT.

On the 10th of last month the warehouse and store of the Fred W. Muth Co., 51 Walnut St., Cincinnati, was visited by a destructive fire. Evidently the fire had been smoldering for hours and finally broke out in early morning. There was \$30,000 worth of goods in the building, on which there was an insurance of \$22,500. As there was not an entire loss, the company probably will not lose much. A new building has been rented at 204 Walnut St., within a square of the former location, and the company will be able to do business again within a couple of weeks at the furthest.

UNRELIABLE PRESS REPORTS CONCERNING HONEY.

In our issue for Aug. 15, page 509, we published a statement from the *Montrose Press*, in which it was predicted that the crop on the western slope of Colorado would amount to 35 or 40 carloads this year. This clipping was sent us by a correspondent, and we supposed it was reasonably correct or that he would not have sent it; but we have been informed by several parties that the crop will be only about one-fourth of the amount stated.

We are very sorry that the statement appeared; but it is almost impossible for us at long range to know whether all the statements made about the honey-crop conditions are correct. However, we have about decided that we will no more accept statements concerning crop conditions from the ordinary newspaper. In the mean time we hope our friends all over the country will take pains to give us the exact facts. It is our sincere desire to publish only the truth.

CANADIAN GOVERNMENT BULLETIN ON BEES.

THE Division of Entomology of the Canadian Department of Agriculture has issued Bulletin No. 2, by C. Gordon Hewitt, D.Sc., Dominion Entomologist, entitled "The Honey Bee." This bulletin is very full and explicit, and will be of immense help to beginners especially in Canada. In fact, as the introduction states, the bulletin is prepared especially to answer the following question, which is asked in countless letters that are continually received: "I should like to keep bees, and should like to have you tell me how to begin and what to do."

The beginner is taught *how* to begin, and how to locate the apiary. Excellent advice is given regarding equipment, and simplicity of fixtures, etc., and then follows a description and explanation of various paraphernalia connected with the business. A few helpful notes on the habits of bees and their natural history are given; but the leading part of the bulletin is devoted to management, and also to that all-important phase of the question, disease and its treatment. The illustrations from our own "Farmers' Bulletin" No. 442 are used, showing the conditions of the dead larvæ of both varieties of diseases.

Among the half-tone illustrations is a very fine picture of the Sibbald hot-water wax-press, which was described some years ago in these columns. In brief, the Sibbald press uses a can large enough to re-

tain a large quantity of hot water, which prevents the slumgum from chilling. There is no heat underneath while the pressing is going on.

The relation of bees to flowers and fruit comes in for a very clear explanation with illustrations. If all Canadian fruit men could read this part of the bulletin they would see at once the tremendously important part that the bees have in accomplishing the pollination of the blossoms.

Residents of Canada can probably obtain this bulletin free of charge, the number of which is 69, by addressing The Government Printing Bureau, Ottawa, Canada.

NOT ENOUGH OF COMB HONEY IN PROPORTION TO THE AMOUNT OF EXTRACTED HONEY PRODUCED. THE VALUE OF SUPERS FOR THE PRODUCTION OF BOTH COMB AND EXTRACTED HONEY.

A REVIEW of the market for several issues back would seem to indicate too much extracted and not enough comb of No. 1 quality. We intend to preach the doctrine of producing more comb until conditions are more nearly equalized. We are glad to note an increasing demand for comb-honey supers adapted to the production of both comb and extracted honey. The two outside rows have extracting-combs, while the center rows have sections with full sheets and bottom sheets. As the season tapers off, as it is bound to do, the dribblets of honey are lodged in the extracting-combs on the outside, while the sections in the center, if the management has been right, will be filled so as to make a No. 1 or choice comb honey. Such supers also, besides eliminating to a great extent unfinished sections that never ought to be put on the market, are well adapted to localities where the honey-flow is of short duration, making it possible to secure only a limited number of sections. But because the seasons have been poor of late, producers have been running more and more to extracted. A weak colony in a good season or a strong colony in a poor season will produce more in extracting-supers than in comb; and this is one potent reason why there has been a dropping-off in the production of comb in favor of extracted. But a combination super, it should be understood, eliminates to a great extent the difficulty of producing comb honey with a weak colony in a good season, or a strong colony in a poor season. Producers will be making up their orders for supplies soon for the coming year. Many of them, if not all, will do

well to try out the combination supers. Some of our most extensive beemen now recognize their efficiency, and are using them in a large way. Among this number we would mention Mr. E. D. Townsend, of Remus, Mich., well known to our readers.

A NEW SPECIAL NUMBER SUGGESTED.

In response to our request for ideas on special numbers, there have been a number of ideas suggested, concerning which we shall probably have something to say later on. At this time we wish to mention an idea given us by Mr. Morley Pettit, Provincial Apiarist at the Apicultural Department of the Ontario Agricultural College. We give his letter herewith in full.

In reference to special numbers of GLEANINGS, I have appreciated and enjoyed them very much. The idea is an excellent one.

There is a difference of opinion among some of our Canadian beekeepers in out-apiary management as to whether it is better to have a complete outfit at each apiary, and travel from one apiary to another with a horse and buggy, motor cycle, bicycle, or automobile. On the other hand, some consider it much better to have one settled establishment, and then use a team or motor truck to haul the supers home for extracting, bringing every thing home in the fall and then again in the spring.

As a number of our beekeepers are considering establishing out-apiaries, and others are dissatisfied with their present arrangements, it seems to me a discussion of this most important question in a special number would be of value some time before spring.

We believe this kind of special number would prove very practical. We are here reminded of the fact that quite a large number of our readers have written, expressing appreciation of the automobile number, and requesting that we have another one. Now, it occurs to us that a good deal of helpful material along this line would be very appropriate in this special number on equipment. In other words, if you believe in a central extracting plant, and use automobiles or auto-trucks to carry the combs to it, let us hear from you, and, if possible, give us good clear photographs of the truck that you use, and also of your extracting plant.

On the other hand, if you have an extracting outfit at each apiary, and make the trip with your helper to do the work, and then later have the honey hauled home, let us have the particulars, with reasons why you think the plan is the most economical.

There is a third plan which quite a number follow, and this is to have a portable extracting outfit—really an extracting-house on wheels. This is drawn from yard to yard, the honey being hauled on the return trip.

Then there has been in the past quite

a discussion as to the relative merits of using one large extractor instead of two or more smaller ones. There are advocates of both plans. We should like to have this discussed also in this special number. Do you find it better to have one eight-frame extractor or two four frames? In this connection, Mr. R. F. Holtermann, of Brantford, Ontario, Canada, has gone so far as to have one twelve-frame extractor built to order; and after testing it this past season he expects to give us the particulars.

Some of these plans have been illustrated at various times, but we should like to have them all brought together in one special number. We will announce the date of this a little later, but it will probably be one of the early numbers of next year.

Of course it is to be understood that we pay for all material that we use, and we wish to say that, for all articles or photographs that we use in these special numbers, we shall expect to pay a little more than our usual rate. So let us have your ideas, and be sure to give your reason why you think your plan is the best. We will make it worth while to you, and we are sure that your ideas will be helpful to other beekeepers who may be planning to make a change.

MR. HOPKINS AND HIS METHOD OF RIPENING HONEY ARTIFICIALLY.

IN our issue for May 1, page 265, we published a letter from Mr. A. Ireland, President of the Canterbury Beekeepers' Association, New Zealand, under the title of "Extracting Uncapped Honey Not Practiced Generally in New Zealand." In this article Mr. Ireland, after stating that Mr. Hopkins stood alone in the matter of ripening honey artificially, so far as the beekeepers of New Zealand were concerned, made this statement:

We had an exhibition here some years ago. Mr. Hopkins, then acting for the government, was running an apiary in connection with the exhibition. At that time he was practicing his plan of premature extracting; but the sample of the honey in Agricultural Hall soured, and started to ferment; yet in spite of such adverse experience he still advocates the plan.

Mr. Hopkins has written us in reply that the honey in question, so far from souring, is still good, even after the lapse of five and a half years; that he has sent letters from eight different persons certifying to the excellent quality of the honey on exhibition at Christchurch. They are T. W. Kirk, Director of Orchards, Gardens, and Apiaries; A. McPherson, Government Field Instructor; Miss Olive Feist, in Charge of

the Government Apiary; Daisy R. Hart, in Charge of Ruakura State Apiary; T. W. Lonsdale, District Agent of the Department of Agriculture; E. P. Brogan, Foreign Manager's Assistant of the Ruakura Farm of Instruction; A. P. Young, in Charge of the Apiary of the Department of Agriculture; and Dr. H. W. Wiley, then Chief Chemist of the United States Department of Agriculture.

We have carefully examined the statements made by these parties, and all of them speak of it in the highest terms.

We are glad to make this statement in justice to Mr. Hopkins; and in the mean time we have written him to send us an article describing his method of ripening honey artificially. While we have generally advised against the practice, believing that the artificially ripened product would not be the equal of honey ripened in the hive, we are open to conviction.

LATER.—After writing the foregoing we received a communication from Mr. W. B. Bray, of Deveauchelles Bay, New Zealand, taking issue with Mr. Hopkins in regard to the advisability of trying to ripen honey artificially. As his article seems to be so fairly and candidly written we publish it on page 633 of this issue. While we have no disposition to mingle in the controversy between Mr. Hopkins and his friends on the one side, and Mr. Ireland and Mr. Bray on the other side, we may say that the general experience in this country is decidedly against trying to ripen honey artificially. The people who have made the largest protest are the large buyers of honey—men who would know whether artificially ripened honey is the equal of that ripened by the bees. In saying all this we are not inclined to doubt the ability of Mr. Hopkins to ripen honey artificially, just as he says he can, in his locality and under his conditions. But as our correspondent, Mr. Bray, points out, atmospheric conditions have every thing to do with success or failure of the artificial method of ripening honey. This explains why some not so favorably situated do not meet with success.

We still solicit an article from Mr. Hopkins, who is one of the best authorities on bee culture in New Zealand. Doubtless he will take up these various questions connected with the proposition. In any case, no one can doubt his sincerity, and we are convinced, in view of the testimony that he has offered, that there must have been some mistake about that particular honey souring in Agricultural Hall to which Mr. Ireland refers.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

EDITOR GERSTUNG adds formic acid to sugar syrup to aid inversion. — *Deutsche Bzcht.*, XII.

BEES are reported as going down 70 feet into a well after water. — *South African B. J.*, 74. [This seems doubtful.—Ed.]

THE FIRST Rietsche foundation-press was sent out in 1883. In 1909 the number had reached 50,000. — *Schweiz. Bztg.*, p. 198.

"A BIRD DOG at Mount Vernon attacked a beehive in a playful mood. The bees stung the dog to death." — *Chicago Record-Herald*. Next time that dog feels like attacking a beehive it will first inquire whether the beehive is in a playful mood. Also whether there are any bees in it.

EDITOR GERSTUNG says, *D. Bzcht.*, 87, that bees generally supersede their queens during the time of building up in the spring. I think that for every one of my queens superseded before the harvest, 10, if not 20, are superseded after it. How is it with others, and what should make the difference? [Same here.—Ed.]

C. P. PALMER writes the same thing that N. Fred Gardiner says, p. 525: If a man faces the south his right side will be toward the west, and it's the same with a hive. No doubt that's right, and it's a good thing to have it settled, for sometimes that side is called the right side that is at one's right hand as he stands facing the hive.

CHAS. H. WALKER, p. 417, you'll probably never produce sections without a good many unsealed cells next the wood; and if "one or two cells" are enough to drip in handling, then these cells are not fit to ship. The remedy is to keep them in a place so hot and dry that the honey in the unsealed cells will become too thick to drip.

FRANZ RICHTER, the wide-awake lookout man of *Bienen-Vater*, has my thanks for helping out about who originated that way of getting cells built in a horizontal frame. It should be labeled "Made in Austria," not "Germany." J. Stumvoll was the originator, and I got it from *Bienen-Vater* and mentioned it in a *Straw*, April 15, 1909, p. 224.

YOUNG BEES gone astray are the worst stingers. So one is likely to be stung when working at a hive while the young bees are at play, for then they are thrown astray and become cross. — *Leipz. Bztg.*, 77. That's given on the authority of Weygandt and the editor; but has any one noticed any thing of the kind on this side? [We have had no such experience.—Ed.]

IRON in the blood is a matter of the greatest importance. The great trouble, where it is lacking, is to administer it in such form as to be assimilable. You may feed a man a keg of nails without getting much iron in his blood. It is not as well known as it should be that honey contains iron in shape to pass directly into the circulation. As shown in a table, *Schweiz. Bztg.*, 158, honey also contains phosphorus, chlorine, lime, sulphur, magnesia, silicon, potassium, natron, and manganese. Some or all of these are needed in the human system, and here they are in just the right shape. That makes honey in all cases a valuable food, and in some cases a valuable medicine. Sugar can not fully take its place, either for folks or bees.

THERE is not so much danger of giving too many empty sections to a colony if you keep in mind to wait until the bees have at least made a start in the outside sections of the supers already on. When the first super is only a quarter filled, if it's overflowing with bees, and every prospect of a big yield for many days, there's not such a very big risk in putting an empty super under—and even another on top—*provided* the bees have made a good start on all the sections clear out to the corners. But if there is still untouched foundation at the outsides, and you add another empty, the bees are likely to begin in the center of the new super before starting the outside sections of the old, and there will be a tendency in both to have sealed sections in the center, and empty foundation at the outside.

EDWARD HASTINGS, p. 418, rural mail delivery must be exceptional with you. "In this locality" carriers could double or quadruple their loads without increase of time or pay, and take just as long trips; and if the business should so increase that extra teams should be needed, there would still be money in it at the price charged per pound. I suspect parcels post will prove cheaper than you think, and that country merchants will be surprised to find it an advantage. [What you say concerning the possibility of rural mail-delivery carriers being able to carry double or treble the loads they now carry, without any increase of time or pay, would apply in this locality so far as we have observed. In driving to and from our beeyards in all directions we meet mail-carriers every day, and therefore we have a fair opportunity of forming an opinion.—Ed.]

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

The Ontario Beekeepers' Association will hold its annual convention in Toronto during the week of Nov. 12. The program is not yet prepared, but due notice will be given later as to place of meeting, hotel and railway arrangements, etc.

* * *

Owing to a misunderstanding on the part of the directors of the national exhibition held in Toronto this year the exhibit of honey is very limited, only one of the usual displays being in evidence. The other exhibitors this year had fine crops, and arrangements had been made for a record exhibit, when the unfortunate matter alluded to knocked out all their plans. Not being in full possession of the facts in the case, I will wait till next issue before referring to the matter more fully.

* * *

A WARNING.

Reference has been made to the unusual amount of brood in the hives at this date, Sept. 7. That means either starvation this winter or a heavy feeding bill for sugar. While the specialist beekeeper is not apt to be caught napping, this reminder is given for the benefit of those who have a few bees, and always depend upon enough being in the brood-nests for winter. Colonies run for comb honey may be all right; but if run for extracted honey they certainly will need feeding in all sections where conditions are like those here in York Co., Ontario, this season.

* * *

CLOVER PROSPECT GOOD FOR NEXT YEAR.

In glancing over my department for Sept. 1 the reader will no doubt wonder at the contradictory items regarding the weather conditions here in Ontario during past summer, as in one place reference is made to the extreme heat and then again I speak of the very cool weather during basswood bloom. This is explained by the fact that the two items referred to were sent in at different times. As a matter of fact, the only really hot weather we had this season was during the first two weeks of July; and since then we have had a long spell of unseasonable, cool *wet* weather that has knocked out all our expectations of getting a bumper crop of buckwheat honey from our yards this year. While some surplus has been stored from

the buckwheat, yet there is not a quarter of what we would have had with seasonable weather. For some reason the brood-nests are more crowded with brood at this date (Sept. 3) than I ever knew before, and of course that will mean lots of young bees for winter; *but* it will also mean a heavy feeding bill to get them in shape for good wintering. But all the rain we have had has not been an unmixed evil, as never before have I seen such prospects for al-sike clover. There are hundreds and hundreds of acres of it; and it is so thick and rank on the ground that much of it is blossoming and growing right up among the shocks of grain, which in many places are still in the fields, owing to the unprecedentedly long spell of wet weather.

* * *

COLONIES IN POOR CONDITION WINTER BEST IN A CELLAR.

That symposium on wintering, Sept. 1, is interesting; and on looking over the various articles on the subject I am reminded that a promise was made last spring to furnish an article with illustrations showing the successful caves used for wintering my large apiary in the county of Leeds. While I entirely forgot the promise, owing to being very busy during the past few months, at some future time I hope to describe this simple building that winters so successfully. After all is said and done on the matter of wintering, there will still be advocates of both indoor and outside methods, right in the same locality, all owing to the different conditions found in cellars and other repositories, as well as the different methods taken of wintering outdoors. One thing is certain, and I have learned this by experience with the caves referred to—in a perfect wintering repository bees will winter with little preparation and a small amount of stores when they would die outright if packed in the most approved methods outdoors. On the other hand, if *strong* colonies are given abundance of good stores, and protected in any of the approved ways, they will winter far better than if just as well provided with stores, and wintered in a poor repository. From the fact that perfect wintering repositories are the exception rather than the rule, and that good outdoor wintering can be secured by all, providing proper care is taken, the latter method is and will continue to grow in favor among men who are in the business extensively, and have to keep their bees in different localities.

Beekeeping Among the Rockies

WESLEY FOSTER, Boulder, Colo.

SUNFLOWER HONEY.

We are having our honey this year well colored by the flow from the sunflowers. This is the first year that enough nectar has been collected from them to color our alfalfa and sweet-clover honey.

* * *

WHEN TO CUT ALFALFA.

The older stockmen and ranchers still maintain, in the face of the advice of experiment stations, that alfalfa should not be cut till in full bloom, and so I saw many fields of beautiful purple on the western slope that were a joy to the heart of a beekeeper.

* * *

NO NECTAR IN CLEOME THIS YEAR.

Cleome, or Rocky Mountain bee-plant, is to be found in large quantities over the whole State; but so far it seems to be yielding no nectar this season. Many beemen had hoped that it would furnish a fine fall pasture for the bees, but this does not seem to be probable this year.

* * *

Sweet clover is ten feet high beside our orchard, and a man on horseback would almost be lost in the luxuriant growth. The season has been a wet one for Colorado, and the clover is yielding honey well. Southwestern Colorado has red soil, and the sweet clover there is more fragrant, and I should judge it secretes more nectar than in Northern Colorado.

* * *

STEALING HONEY.

Honey thieves tried to drive the bees from one of my filled supers with a shotgun, half a dozen shots being fired into it. The super was pulled off and put into an irrigating ditch to help get the bees out. The hive was tipped over in getting the super off. Mud and dirt were daubed all over the honey. The thieves were run down by a young farmer, and their names secured. He knew most of them. They all had guns, and had been out hunting; but he, unarmed, caught and lectured them. The outcome will be interesting.

* * *

THE ROBBER TENT.

Last fall Robert E. Foster, county bee inspector for Montrose County, and myself, made a tent without a top, as described by the editor, August 15. We got the idea from Dr. Phillips. Perhaps he got it from the editor. The tent worked all right for fall inspection if the apiary was not too large; but the bees finally do find their way

over the top of that tent. Ohio bees may not, but Colorado bees have a habit of finding all six sides of a cube—perhaps from their experience with the steep sides of the Rocky Mountains.

* * *

MAKING THE LOAFERS GET TO WORK.

Bees which cluster on the outside of the hive are wasting their time. A hatful of them could fill a super in a week. Try this plan: Lean a drawn comb beside each outside cluster. The bees will soon desert the side of the hive for the comb. When eight or ten of these combs are covered with bees, beside as many hives, put them all together into a hive; screen them in, and haul to the next apiary. In three or four hours they will be very glad to have a virgin queen run in among them, and such a colony will work with the vigor of a new swarm.

* * *

UNOCCUPIED BEE TERRITORY.

Colorado has a good number of unoccupied fields for beemen, as a trip of investigation will show. A few districts are overstocked, and it is not necessary to warn against locating in these places. There is hardly a county where a person could not buy out one or more apiaries, getting the range with the purchase. Beekeeping is not so profitable that there is much crowding. Winter losses, foul brood, arsenical spray poisoning, honey failures, have all combined to make a cloud which at least has no *golden* lining. We hope a *silver* lining will still be in evidence.

* * *

FEEDING BACK EXTRACTED HONEY FOR COMB HONEY PRODUCTION.

The inter-mountain region is one where feeding back extracted honey for the finishing of bait combs has been a demonstrated success. Some few points should be borne in mind if the best results are to be obtained. The colonies selected to be fed should be strong in bees, and each should have a young vigorous queen. It is important that they be good wax-builders and white-comb makers. Feeding should be started before the honey-flow has ceased. As the flow tapers off, the feeding should start. Combs of even capping and color should be placed on hives doing a corresponding class of work. The feeding should be discontinued when the weather gets cool. September is the last month for successful work, and August is the month to begin. Such colo-

nies, if they have young queens, will winter in well-nigh perfect condition, and are worth three of the ordinary colonies on April 1 of the following year. This feeding will stimulate breeding, and will wear out an old queen, ruining the colony during the winter; it is a fine test for a failing queen, and all such should by all means be superseded at the earliest date. Lastly, it may be stated that only the whitest honey should be fed for the finishing of white comb honey.

* * *

BULK COMB HONEY.

Some of the Arkansas Valley beemen cut out their unfinished sections of comb honey and pack them in 60-lb. cans, and then pour extracted honey (heated) over the combs. This is the only bulk comb honey that I know of being put out in Colorado, and there seems as yet to be no trouble with granulation. The amount produced is small, and it is all sold before Christmas. The weight runs around 55 to 56 pounds net, and the honey is sold by the can, not by weight. This honey brings \$6.00 a can—about 11 cents a pound.

The only way, as I see it, to put up comb honey in bulk is to fill the can full of the combs and then fill in with extracted. Trying to make up weight by putting in more extracted and less comb is simply dodging the question. Of course, if the buyer wants just a little comb honey in the can of extracted, it can easily be put up that way; but it is not bulk comb honey; it is extracted honey with some combs in it.

* * *

A LATE FLOW.

About August 15 the weather turned cold, especially the nights following a rainy spell. The bees deserted the supers and ceased swarming, and carried all the honey stored in the unsealed cells of the sections to the brood-chamber. The weather warmed up again about the twentieth of the month, the warm nights returned, and the third crop of alfalfa came in bloom. The bees returned to the supers, and at this date, September 1, they are finishing honey in good shape. If the flow continues for two weeks the crop in northern Colorado will be a third larger than it would be with no nectar from the third growth of alfalfa. Honey from the third crop is something that we do not get once in ten years, on account of the cold nights. A fine rain has just started the sweet clover with new bloom, and the hot days put the nectar there for the bees. The rosinweed is in bloom, and this furnishes a yellow and very inferior honey. If the alfalfa and sweet clover yield well we hope that the nectar

gathered from the rosinweed will be negligible in amount. Rosinweed honey granulates very soon after being stored in the comb.

* * *

THE COLORADO HONEY REPORT.

The crop conditions in Colorado were fairly accurately reported in the August 15th number, except the report taken from the *Montrose Weekly Press*, which reported a far larger crop than will be harvested. Montrose was credited with six or seven cars, while two cars of comb honey will be the very most in car shipments, and no cars of extracted will be shipped from Montrose. It is possible that three cars of comb and extracted honey may be produced in and near Montrose, but it is doubtful. The local shipments take a considerable amount, and some honey is used in the local markets.

If ten cars of comb honey are shipped from the western slope this year I shall be greatly surprised, and that will be about as much as went out last season. Twenty-two cars of comb honey were not shipped from western Colorado last year, as stated, nor of comb and extracted combined. The total shipments from all of Colorado will not total thirty-five or forty cars. I think that a newspaper report without authoritative data may do a great injury to the honey market.

The Arkansas Valley may ship two cars of comb honey to the eastern markets, and as much as one or more cars may go east a short distance by small local shipments. No cars of honey will be shipped from Fremont County. Two cars of honey may be shipped from Montrose. Not more than two cars of comb honey will leave Delta County, as there is considerable extracted honey produced, and the loss of bees has been heavy. Mesa County may ship as much as three cars of comb honey, but I do not know where it is all coming from. Extracted honey is produced by the larger beemen. Garfield County may ship one but hardly two cars of comb honey, and no cars of extracted. Northern Colorado may have ten cars of comb honey, and I know of six or seven that are quite likely to materialize. Southwestern Colorado, comprising La Plata and Montezuma counties, will have no carload shipments of comb honey, while several hundred cases may be shipped by local freight. Most of this is consumed in the local markets.

It should be borne in mind that the honey-flow is not over with at this date, September 1, but is likely to close at almost any time, and probably has closed in some parts of the State.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

Ex-President B. G. Burdick, of the State Association, is nursing a broken foot, due to his automobile moving without caution.

* * *

Try burlap in your smoker. I find it surpasses any other fuel I have ever used for cheapness and convenience. Nearly every one has some old burlap bags lying around.

* * *

Mr. Crane, I did not intend to imply on page 297, May 15, that sealed brood in any stage would stand a temperature of 40 degrees for I do not think it would, though I have never tested it thoroughly. What I mentioned was the fact that mature bees hatched three days after being exposed to a temperature as low as 40 degrees. The nearer mature, the more cold they will stand.

* * *

In a dispatch from Portersville, Cal., clipped from the Los Angeles *Tribune*, Mr. Robert J. Smith, in writing of the cause and cure for the June orange drop, recommends the spraying of orange-trees. I infer from Mr. Smith's article that this would be done during the blooming period, though this point is not made clear. Should this be the case, and come into general practice, it would be a sad blow to the beekeeping industry in the orange districts.

* * *

On page 525, Aug. 15, Walter C. Bennett takes a "hot shot" at the editor of this department as well as the editor in chief. Mr. Bennett wants a large piece of pork to make him swallow the report I gave of an average of 700 lbs. per colony for Orange Co. in 1884. Can't some of you old-timers from Orange Co. come to my rescue? We are rather short on pork in these parts; but I look for a return of one of those bumper seasons some time that will produce enough honey to wash this story down for Mr. Bennett. I may say, however, that a yield of 500 lbs. for a single colony is not at all uncommon any good season now, though much above the average, and we do not use box cars either.

* * *

A prominent beekeeper recently suggested to me that honey taken from over excluders, free from brood contamination, should bring at least one cent more per pound than where no excluders are used,

and more or less larvæ find their way into the strainer, or even into the honey-tank. Sometimes I fully agree with this gentleman's suggestions, though at the same time I realize what a howl will go up from many beekeepers at this suggestion. Perhaps the quickest way to bring this about, were it possible, would be to parade the consuming public through honey-houses at extracting time where the excluders were and were not used.

* * *

BEES DO NOT PREFER LARGE ENTRANCES.

Mr. Crane, page 363, June 15, seems to have found grounds for entrances as large as those of Mr. Latham or Arthur C. Miller.

A close study of the natural tendencies of the bees leads me to the conclusion that large entrances are neither sought nor desired by them. There is no question but that they select some very large entrances; but this is due often to inability to find a better place readily. I have watched the scouts in the woods searching for a habitation. With a zigzag nervous flight they will move up and down a tree only an inch or two from the bark, searching for an entrance to the body or limb. If they were in search of a large entrance their close searching flight would not be necessary. In the majority of cases they select a small knot-hole or crack through which to enter the cavity. Here in town, where where they have made their homes in houses they have nearly always entered through very small cracks or knot-holes. There is a swarm in the First M. E. church of this city that enters a crack $1\frac{1}{2}$ inches long by $\frac{1}{4}$ inch wide. The desire for a small entrance is undoubtedly for protection from robber bees, other insects, and small animals, as well as from inclement weather. I use a $\frac{3}{8}$ -inch entrance across the front of my hives, and find it ample for all purposes, even under the scorching sun of our midsummer skies.

General Honey-crop Report from the Southeast

Reports of the summer honey crop have come in from almost all sections of the Southeast, and we are able to make a definite report from our section. The honey-flow has been very heavy over the partridge-pea and clover section, and also over the great cotton belt; and a great honey harvest has been the result, such as we have never experienced before. This was due to ideal weather conditions. Local showers have been frequent over almost all sections, causing a most vigorous growth of the honey-plants. The temperature has been high and the wind has been calm, making conditions ideal for a great honey harvest, and for which we are very thankful.

Cordele, Ga., Sept. 14.

J. J. WILDER.

Conversations with Doolittle

At Borodino, New York

BUILDING AN UNDERGROUND CELLAR.

"Mr. Doolittle, I am thinking of building an underground cellar for wintering bees, as I find that this plan is much talked about in the bee journals."

"Well, Mr. Barber, any one who proposes to build a cellar to be used solely for wintering bees should first count the cost; and the advantages and disadvantages of cellar wintering should be looked into, so that as few mistakes as possible may be made. Most of those who winter in a cellar do so to protect their bees from the severe weather. You will remember that last year, from the first of January right through to the middle of February we had one continuous siege of cold weather when the thermometer was anywhere from 25 below zero up to zero, while at the same time winds were blowing that carried this cold air into every crack and crevice. The advantage of a cellar under such conditions is far-reaching, in that it allows us to economize to the greatest possible extent on the consumption of stores by the bees, and at the same time the per cent of loss is decreased to two per cent, and the vitality and vigor of the bees that live over are conserved to the greatest degree."

"But you have mentioned disadvantages of cellar wintering. What are they?"

"The disadvantages can be summed up thus: The labor required in carrying the bees in and out of the cellar, the difficulty of caring for any individual colony which may require looking after, without disturbing all the other colonies in the cellar, and the difficulty in controlling the temperature in the cellar. This last disadvantage is the most serious of all. When the sun gets around in the north in the spring, and damp still weather prevails, the temperature in the cellar often has a tendency to run too high, thereby exciting the bees. The excitement induces untimely breeding and a wearing-out of the vitality of the mature bees, which may bring on bee dysentery or death, and which also causes spring dwindling, so that many of the colonies become too weak to be of any use when the harvest of white honey begins. When I wintered bees in the cellar under my house I could control all conditions until about the middle of February or the first of March, and I thought there was nothing like this plan of wintering; but all at once the weather would change, and the thermometer would jump to 40, 50, and even 60 degrees, while the air would be muggy and damp. At such a time

the roaring of the bees in the cellar would sound like the rushing of the wind through the bare and leafless trees in the forest, and the bees would come out and die on the cellar bottom till they could be swept up by the bushel."

"But I thought this state of affairs could be prevented by opening the doors at night or carrying the bees out for a mid-winter flight."

"I know that some advise this; but opening the doors at night always seems worse than nothing when the air outside is warmer than that inside; and carrying the bees out for a flight and taking them back again makes a lot of extra work, and the results are not enough better to pay for it. After trying all of these plans for several years—for example, setting a part of the colonies outside and leaving the rest inside till all of them could be taken out for good, as well as opening the doors at certain times and keeping them shut at other times—I came to the conclusion that the bees were just as well off by May 10 if they and the cellar had been left entirely alone."

"But you do not propose to winter under a dwelling-house; therefore, when building your special cellar, you can so design it that it will afford proper protection during these warm spells, so that the temperature remains unchanged throughout the winter and spring. You will thus have only two main points to be kept in view—proper protection and convenience of access."

How Long Does it Take to Nail Together Five Hives?

I made the following notes on setting up: Five ten-frame dovetailed Root hives, R. cover, no supers. I did not nail the hand-hold blocks on. Commenced work at 7 A. M.; at 10.45 A. M. division-boards nailed; frames nailed, stapled, and wired, ready for foundation. At 1 P. M. bottom-boards and covers done; nails countersunk and puttied. At 1 to 2 P. M., rest. At 3 P. M. I set up the fifth hive body; countersunk all hive-body nails, and puttied nail-holes; nailed in from rest tins, having now hives complete for paint. At 4 P. M., priming coat done; bottom-boards primed all over.

Galena, Kan., July 20. J. P. BRUMFIELD.

Six Inches of Leaves for Packing

I winter my bees on the summer stands by setting a box without bottom and with a movable cover over the hive, and packing about six inches of leaves on all sides and on top of the hive. The covers have a slope of six inches, and a bridge at the hive entrance gives the bees a flight at any time. No losses.

Payson, Ill.

DANIEL E. ROBBINS.

Mending the Cappings with Paraffine

I produce fancy comb honey in a limited way, and I find that my finest sections are frequently damaged by being broken, or the cells uncapped. As I use paraffine in numerous ways, I hit on the plan of mending the cappings with warm paraffine. Dayton, O., July 16. EDNA T. MAUTINS, M. D.

General Correspondence

A BEE-LINE THAT WAS NOT STRAIGHT

How Various Conditions Change the Line of Flight

BY J. FORD SEMPERS

Most of us have been accustomed to accept without question the teaching that the bee's flight for home with her load of nectar or pollen is in a perfectly straight line. The "bee-line" has become the synonym for straightness itself. Possibly we owe this belief to the bee-hunter's tactics, who, in liberating a bee from his box, is guided by the course which it finally takes after having made its preliminary circles about him in finding its bearings. It is not likely that the hunter or any one else knows how the bee flies after it once gets beyond the range of vision. It may go in a straight line or it may not, and he is none the wiser. All he knows is that it started in a certain direction, presumably toward its home.

There are certain combinations of light and shade, topography and atmospheric conditions, by which it is possible to watch the flight of an individual bee for a considerable distance, a hundred yards or more.* For example, my yard is something more than that distance from a favorite moist sandy stream-bank to which the bees go in great numbers for water. The yard is on a hillside perhaps fifty feet above the stream. One can, therefore, stand near the apiary

in the valley below. This short flight is in a straight line if the air is calm. I have not been able to watch the course taken when a strong wind was blowing except when it came from the northeast. With such a wind the bees invariably describe an arc of a circle, the "bend" going toward the direction from which the wind is blowing, and the curve becoming deeper as the wind increases. Whether the bees behave in the same way when making a flight of one, two, or three miles is a question likely to remain unanswered unless possibly under some unusual circumstances, as in the present case I am relating, where conditions favor the definite outlining of the course taken.

While it is next to impossible to watch the flight of a single bee except for a very short distance, there is not so much difficulty in following the line established by a large number of bees between the apiary and some attractive forage grounds, when there is a general dearth of nectar or pollen elsewhere. During a general honey harvest the bees are scattered in every direction, and there is no way of knowing what course is taken after once the bees are beyond one's vision. Conditions favoring the formation of what I may for convenience call an audible or visible bee-line are just the opposite of those existing during a general honey-flow, since in the case favoring the

and look down the long line of flying bees. With the sun at one's back, and by the aid of a clear atmosphere, there is no difficulty in following with the eye for over a hundred yards an individual bee as it is silhouetted against the background of woods

* One hundred and forty good long steps by actual measurement.

formation of a bee-line, the bees are all concentrated toward a comparatively small spot. They are all moving over the same course to and from the apiary—all bent on the same errand, with the result that we have a buzzing, roaring, aerial bee highway between the apiary and the point being visited.

Under favoring conditions it is not so difficult to follow such a bee-line for fractions of a mile at least, depending mainly as a guide on the noise made by the bees. It is one of these bee-lines that I shall endeavor to describe. In the past ten or more years I have noticed a number of them. The one illustrated by the accompanying diagram occurred late in August, 1901. The diagram was made at that time. A number of other lines have taken place since, but these were less pronounced, or at least not so easily followed. It is very noticeable, if the weather is fair with little wind, that the course taken is apparently straight and high in the air. If threatening, lowering weather prevails, the flight is low. In the case of high winds I presume the flight may become any thing but an orthodox bee-line. The diagram shows how completely the bees have altered their course (at least in this instance) that they may make the most of prevailing conditions.

It was by accident that my attention was called to this spectacle. I had been working for several days on an out-building near the beeyard (to the west of it), and had noticed the line of bees passing daily back and forth over my head. The weather was warm, humid, and threatening rain, which, however, did not come, so the conditions were just right for nectar secretion. This was followed by a sudden clearing at night, a decided drop in the temperature, and high north winds. Resuming my work in the morning following this change I at once missed the busy hum overhead, and concluded that the change in the weather had cut off the nectar. Glancing over at the apiary I was puzzled to see the bees still working almost as busily as ever. My curiosity was at once aroused. I soon found the bees were flying in a nearly northerly course instead of the westerly direction which took them straight to the buckwheat before the heavy wind set in. Following the new line I found the bees were heading for a belt of timber to the north of the apiary, which extended in a westerly direction to the buckwheat. The line turned rather sharply to the west just before reaching the timber, the bees flying just below the tree-tops, *out of the wind* until the buckwheat was reached. They were quite

low; and as a part of the course ran parallel with a public road they attracted the attention of passersby, several of whom asked, "What is the matter? Are your bees going to swarm?"

At points just west of the stream (*a* and *b* on the diagram) the bees flew remarkably close together, and the very loud hum could be heard by one approaching, long before a bee could be seen. The bees in the fair-weather course were invisible except a few stragglers who evidently made up the lower edge of the line.

I have noticed once in a while in GLEANINGS some reference to these bee-lines, but am uncertain if the subject has been dealt with in detail. Possibly the topography may have played an important part in the behavior of the bees.

I may add that the belt of timber referred to extended unbroken for a mile or more to the north and west of the buckwheat-field, thus giving the bees a complete windbreak. I should also explain that buckwheat is seldom sown here, and it rarely happens that more than one field is within range of the bees at the same time. Coming into bloom at a time when there is a general dearth of nectar, the bees make a great fuss over it every morning as long as it lasts.

Aikin, Md.

THE EFFECT OF WINDBREAKS IN WINTER

Tenement Hives and Outyards

BY H. G. QUIRIN

The Sept. 1st issue ought to be worth a small fortune to the beginner, as it deals with one of the most vital problems that he has to contend with. We, too, thought that a tight board fence would be a fine thing as a windbreak; so, three years ago, we constructed about sixty rods seven feet high; but last winter changed our mind on the subject, as the snow drifted inside the fence four to six feet deep. It packed, and eventually formed solid ice far above the entrances; to give them air we dug down to the covers and raised the cushions; but most of the colonies having ice above the entrance of the hives did not come through in very good shape. Were it not for our queen-rearing nuclei we would certainly take down this fence, but find it a fine thing to shield them from the winds in early spring.

We have another yard located on the south side of a woods. This woods is about as bad for catching the snow as the tight board fence. We have still another yard

located right out in the free open, and one would naturally suppose this yard would have perished; but the colonies wintered nearly the best of all. The only protection this yard had was some buildings about forty rods away on the west side, and a small copse sixty rods to the north. There was nothing around these hives to catch the snow, and the ground had not more than six or eight inches of snow on it at any time. Then as soon as it warmed up the snow melted and the ground was bare. Not so at the other two yards. There was ice around the hives and nearly over the entire yard till quite late, and every little sunshine that brought the bees out caused them to drop in the puddles of water, and the colonies kept growing weaker.

We have a fourth yard, which was located in a hollow or sort of cove. This yard usually winters without the loss of a single colony, and on our last visit last spring nearly every colony covered ten frames. It seems, however, that fate decided that these bees should not gather honey for their owner; for, a day after our last visit, the sun came out warm, and the snow was turned to water. The bees were located near a river with an ice-jam a few miles below, and a milldam a few miles above, and when the ice went over the dam it backed water two feet deep into the beeyard. No water was ever known to come up anywhere near the yard, and we have come to the conclusion that rivers, like many other things, can not be trusted.

The hives we winter in are of the tenement pattern, and also the old-style Root chaff hive. The tenement hive winters the bees the best, but it is not so handy to work with. The bees remain in the tenement hives winter and summer, with one large chaff cushion stamped down tight. The four colonies are then in winter quarters, and they require no further attention till warm weather in the spring. These tenement hives are a fine thing for outyards, especially when stock is turned in the orchards or yard, as they are proof against being knocked over; but it takes two to four men or a derrick to load them on a wagon for moving.

Bellevue, Ohio, Sept. 2.

[This problem of windbreaks to shield an apiary during winter is a perplexing one. But we think we have determined that a solid high board fence is not as good as an open fence, nor yet as good as low shrubbery by which the force of the wind may be broken—or enough so that it will not strike the hives with a blast. A solid board fence causes the wind to glance up-

ward. It then dives down, hitting some hives with peculiar force.

We were pretty well satisfied last winter, and especially in the spring, that hives having entrances facing a stretch of country without a windbreak, where the wind could gather momentum, suffered much more than other hives in a more screened position. Indeed, many of the former died outright. Hives with exposed entrances almost invariably were in bad condition.—ED.]

THE ESSENTIALS OF TRUE SALESMANSHIP

BY R. A. NUSBAUM

Can we not get something started in the press that will cause the "mob" to buy honey for the same reason that they buy "grape-nuts," "food shot from guns," "meadow gold butter," etc.? Of course that would cost more money than most of us would care to spend; but I believe it would pay as well as any thing else.

Some of us have sold large quantities of honey by making a personal call at the home. In a very few minutes we have made a good sale to Mrs. Jones, who just a few moments before had never an idea of purchasing any of God's choicest gift to man.

Honey can be sold just as easily as vegetables, books, flavors, etc. In order to do this successfully one must have a carefully prepared speech, or what a book agent calls his "canvass." This talk must be so arranged that it will lead the prospective customer through four distinct mental processes: First, he must get the attention of his prospective customer; second, he must develop an interest in the article sold; third, he must create a desire on the part of his prospective customer to possess this particular article; fourth, he must induce action—the order or sale. In the first place, these four steps are absolutely necessary in making any and every sale.

I venture to say that many beekeepers try to sell part of their crop every year without knowing the very fundamental rules of the salesmanship game. There should be a "canvass" built on attention, interest, desire, and action—the four corners of the foundation upon which all successful salesmanship is built. I think it should not be more than eight or twelve minutes long. A well-worded and balanced canvass should be worth hundreds of dollars to any one who has to do with the sale of honey.

New apicultural building at the Massachusetts Agricultural College, Amherst, Mass.

FIELD MEET AT THE MASSACHUSETTS AGRICULTURAL COLLEGE

BY A. W. YATES

The field-day and special meeting of the Hampshire, Hampden, Franklin Beekeepers' Association, held at the Massachusetts Agricultural College, Amherst, June 12, 13, 1912, was largely attended, many being present from out of the State.

The morning of the first day was given up to sight-seeing and the examination of the products of manufacturers and queen-breeders, of which a large hall was filled. Some of those making these exhibits were: O. F. Fuller, F. M. Keith, A. W. Yates, Dadant & Sons, queens and queen-rearing; H. F. Davis, F. Danzenbaker, Gus Ditmer Co., H. H. Jepson, Kretschmer Mfg. Co., E. M. Nichols, Ross Bros., supplies.

There was also a large collection of hives, implements, honey-packages, curiosities, and literature in the collection of the college, that was very interesting.

The speakers of the afternoon of the first day were A. W. Yates, of Hartford, Ct.; subject, "Bees in Relation to Fruit Culture and Plant Life," and R. H. Holmes, Shoreham, Vt.; subject, "Securing Fancy Vermont Honey." After this a demonstration was given of an electric

foundation-fastener by H. F. Davis. Mr. F. Danzenbaker explained the improvements on his new hive, and showed a case of fancy section honey produced in one of them.

All then adjourned to the apiary building. Dr. Gates explained the features of the new building, including its two floors and basement. Special attention has been paid to lighting and ventilation. On the first floor are a large laboratory and workshop, a room for the separation of commercial honey, and an office. The upper floor has three good-sized rooms. In the basement are the storage rooms for the wintering of colonies, the heating plant, and apparatus for wax-rendering. In the college apiary, which is located in a sheltered place on the hillside above the building, Mr. Keith gave a demonstration of cell-grafting that was very instructive.

The evening was taken up by the address of welcome by President Kenyon, L. Butterfield, and an address by J. Lewis Ellsworth, Sec'y State Board of Agriculture. Dr. James P. Porter gave a very interesting illustrated lecture on "The Life, Habits, and Development of the Honey-bee," showing the different stages of development from the solitary bee.

In the forenoon of the second and last day Dr. E. F. Phillips gave an idea of

Another view of the collection.

what was being done by his department in the federal government in regard to bee diseases and the extent to which they are scattered over the country. He also gave a demonstration of the treatment of foul brood by shaking the bees from the comb. This was watched with much interest. Beekeepers should feel thankful that this Department is taking such an active part in the protection of our bees, and that we have so able and enthusiastic a leader at its head as Dr. Phillips.

Dr. J. B. Paige demonstrated the use of new tools, etc., for beekeepers, and O. F. Fuller showed his queen-rearing outfit in operation.

Methods of shaking swarms, etc., were explained by H. F. Carey and others.

Beekeeping in Massachusetts is coming into its own. Not only are established beekeepers receiving aid, but new comers are being brought into the ranks by the work of the beekeeping department of the Massachusetts Agricultural College under the able direction of Dr. Burton N. Gates. Begun about two years ago in a small and modest way, the department under Dr. Gates has grown in size and scope until now it is doing a really important service to the beekeepers of the State. A thoroughly practical course in management and manipulation offered to regular students

at the college is but one phase of the work which is being done for beekeeping in Massachusetts. A short history of beekeeping as an art supplements this practical course. Other lines of work carried on by the department are State inspection of apiaries with a view to combat and control the two most important bee diseases—American and European foul brood; the offering of courses to those attending the two weeks short course held in May, and general instruction of beekeepers.

The course offered to the regular students is one of the very few given in this country, there being, perhaps, but two other colleges, at the most, giving instruction in this work. Over 85 students enrolled in the course, attesting to its popularity and value. The nature of the work, of course, requires that much of the time be spent in the laboratory. During the winter months the time is occupied with setting up hives, nailing frames and other hive parts, and the study of mechanical hive manipulation. When the weather becomes more mild, considerable attention is given to the management of colonies, the study of swarming, the taking care of swarms, wax extraction, and other important work that confronts the practical beekeeper. Working with the idea that proper management depends directly on the intelligent study of the habits

General view of the apicultural exhibit at the spring convention held at the Massachusetts Agricultural College.

One corner of the exhibit room.

of the bees, so called "rules" for beekeepers are discarded, and much time is given to the study and habits of the different castes of bees. Especial attention is paid to the habits of the queen with regard to swarming. A feature of the instruction is the short course offered to any one desiring to attend. Dr. Gates tells me that ten people registered from outside the regular enrollment of the college, and this would indicate that people at large are not too busy to give two weeks for practical instruction in this fascinating occupation. This is only the second year that the course has been offered, and the outlook for future development in this department is promising.

Since the course is short, only the most practical phases of beekeeping are taken up. A part of each day is devoted to lectures given by various members of the college faculty, and the remainder of the day is given over to laboratory work at the apiary building and actual manipulations of bees in the hive. This includes instruction in controlling swarming, treating bee diseases, getting the greatest total production of commercial honey. Study is also made of the wild flowers offering abundant nectar supply to bees. Of course, the natural range of nectar-gathering workers being so wide (often three miles) the

beekeeper can not hope to control to any little extent even the source of the nectar which his bees gather.

The equipment of the beekeeping department at the agricultural college is probably the best in the country, connected with instruction work. The offices of the department are at present under the same roof with the Department of Entomology. In the same building is a large well-fitted laboratory and paint-shop where the practical indoor work is given. The most complete library of ancient and modern books on beekeeping is owned by the department. Several French and English works on the subject, bearing the printer's date of the seventeenth century, are to be found in this library. In addition there is a museum of objects of interest to beekeepers; hives and appliances of old and of the newest manufacture; a series of hives showing the development of the modern hive, and special tools as well as hives for observation of bees at work.

On the whole the convention was considered a great success. It showed the awakening interest that the people of Massachusetts are taking in beekeeping; and the work done at the convention is sure to kindle new enthusiasm in those who have, for some reason or other, partly fallen by the wayside.

THE SUMMER MEETING OF THE SOUTHERN IDAHO AND EASTERN OREGON BEE-KEEPERS' ASSOCIATION

BY J. E. LYON, VICE-PRES.

One of the most pleasant as well as profitable gatherings of those who devote their lifework to the management of bees and the production of honey was the second annual field meeting and picnic of the Southern Idaho and Eastern Oregon Beekeepers' Association. The summer assembly is a comparatively new feature of the association's work, and was held at the apiary of C. E. Dibble, of Payette, Idaho, July 15. The purpose of this yearly gathering is to bring the apiarists of the State together during the time when the busy bees are gathering their harvest of honey for a good time socially, and afford a suitable opportunity for the discussion of timely topics in apiculture.

Between 35 and 40 of the leading beekeepers of the State were in attendance with their families. They came from such points as Boise, Meridian, Caldwell, Weiser, Payette, New Plymouth, Nyssa, Notus, and Ontario. They represent about 10,000 colonies of bees. Situated in the very heart

"Bee closet" at the apicultural museum, Massachusetts Agricultural College.

The "bee closet" open. The colony and brood-chamber is above the shelf, the surplus combs being below.

of a rich honey-belt of Southern Idaho, and with an apiary of 500 stands near at hand, the beautiful country home of Mr. Dibble was well suited for such a meeting, with its natural beauty and welcome shade.

A most sumptuous old-fashioned family picnic dinner was served out under the trees. The rustic tables were loaded with every thing conceivable to eat, with the hum of bees to be heard in the distance.

The president, W. H. Pennington, acting as toastmaster of the occasion, called the meeting to order. Mr. Dibble, as host, extended a cordial welcome to the assembled beekeepers. In a short talk, A. I. McClanahan, of Payette, expressed his belief in a large crop of honey this year. The editor of the *Gem State Rural*, A. E. Gipson, spoke upon the subject, "Our Sister Beekeepers." Mr. Gipson has been with the association since its organization, and has the utmost confidence in the bee industry.

Professor Wilson, of the Oregon Agri-

The entrance of the "bee closet" through the wall.

cultural College, delivered a practical address to the beekeepers. At Corvallis, where the college is located, Professor Wilson has a large class in beekeeping, a course covering a year's work. He has traveled through various parts of the United States, becoming acquainted with honey-producers. The most important element in the beekeeping industry, he said, is co-operation among the producers, which enables the buyer to secure a higher grade of honey, and the apiarist a greater compensation for his product.

An interesting discussion then followed concerning the relative merits of the single and double tier shipping-case and the best ways to grade honey. Practically all the beekeepers in Idaho use the single-tier case. As to grading honey, general opinion favored the eastern grading rules. All recognized the expediency of a plan by which representative producers and buyers could mutually agree upon a set of rules. A motion was carried for the appointment of a committee to confer and recommend to the winter meeting of the association the best style of shipping, and a uniform

set of grading rules. Crop conditions in Idaho, and the sale of honey were subjects then taken up. The beekeepers of Idaho recognize the folly of cutting prices. They realize that honey will be more carefully graded, and better prices secured, when they do not undersell, and especially when they market their honey through one medium. This concluded the formal part of the program.

BEE PARALYSIS PREVALENT IN SOUTHERN IDAHO.

A subject receiving perhaps more attention than any other, and informally discussed, was that of bee paralysis. This menacing disease is widespread throughout Southern Idaho. Not excepting foul brood it is, perhaps, the greatest enemy to apiculture in this State. It makes its

appearance most noticeably between the first and second alfalfa flows; but it may attack an apiary at any time during the summer. It has been known to destroy the complete working force of an apiary. A shortage in crop can many times be traced to the harmful effects of this disease.

There were almost as many remedies offered as there were beekeepers present. Many apiarists described various methods for treating each hive separately. Most of these methods have failed. The reason for this, we believe, lies in the fact that in Idaho the whole apiary is infected if one hive shows symptoms of it. Such has been our own experience. Bees by the thousand will be found crawling from the hive into the grass to die. But these can be seen only during early morning or on very cool days, which explains how the strength of an apiary can be diminished before the apiarist is aware of it. When attacked by this disease, the abdomen of the bee is greatly swollen, and black and shiny. There is a fluttery motion about the wings. If a personal reference may be pardoned, the most effective way to deal with this disease,

J. M. Lewis' method of packing bees for winter. The colonies are placed under the shed in the fall, thin boards placed in front, and leaves or straw packed tightly around the hives.

judging from extensive experiments made with bee paralysis, is through the agency of salt water, sulphur, and carbolic acid. These remedies have been recommended many times. But the difference of opinion arises as to how they should be administered. Again, referring to our own experience, we have found that in treating paralysis immediate results must be secured. Any such method as requeening when practically the whole apiary is infected is out of question. To prevent is wiser than to cure this disease.

Despite the prevalence of bee paralysis and foul brood, beekeeping in Idaho is a growing industry. While only in its infancy, its future is assured. Idaho is pre-eminent in two industries—agriculture and fruit-raising; and it is altogether probable that, from year to year, orchards whose fertilization is best secured by the bee will continue to be cultivated, while a great abundance of alfalfa, our main honey plant, will be produced. The demand is for specialists, men who thoroughly understand apiculture, so that they may intel-

Field meet of the Canterbury Beekeepers' Association, held at the apiary of the president, A. Ireland, Brookside, N. Z.

ligerly cope with existing conditions. The men who engage in beekeeping in Idaho are a splendid class of citizens. They are building up an industry of which the State may justly feel proud. They are broad-minded and progressive. They adopt the latest methods in beekeeping, as the scientific farmer does in agriculture. Brought into constant relation with one of the most interesting subjects in all science, engaged in a calling which, next to agriculture, is perhaps the most ancient, they respect the rights of their fellow beekeepers. They do not infringe upon another's territory.

It is safe to say that the beekeeping industry will play an important part in the Gem State in building up a great agricultural commonwealth.

Boise, Idaho.

FIELD DAY OF NEW ZEALAND BEEKEEPERS

BY E. G. WARD

I am sending you a photograph taken at our last field day. The members of the Canterbury association, with their friends, went by coach to Brookside, on March 17, to the apiary of the president, Mr. A. Ireland, for their annual field day. The situation is an ideal one, having a large

belt of trees on the south which protects it from the cold winds. There are acres of white clover within one-fourth mile, and plenty of willows. The company was kept in the best of humor by the Scotch jokes and stories told by Rev. Mr. Jackson, of Southbridge. The season in this part of New Zealand has been the worst for 20 years; but we all look forward to a bumper crop next year.

St. Albans, Christchurch, N. Z.

SHED FOR PROTECTION

BY J. M. LEWIS

The photograph of one of my sheds shows how I protect my bees during the winter. The plan has proven very successful in Southern Massachusetts, where we have long cold winters. My method is very simple and inexpensive. I put thin boards on the front and back of the hives, first placing the hives a foot apart, and on a straight line, leaving a space sufficient for the packing. After placing a board above the entrances to allow the bees to leave and enter the hives during weather when they make their winter flights, I pack straw or leaves tightly around the hives. I put on an empty super with a super

cover between the brood-chamber and super with a hole made sufficiently large to take a feeding jar so the bees can be fed at any time when necessary.

The packing on top can be taken off and replaced in a moment, and the condition of the bees determined at any time. My covers are all made with glass in them, so by simply removing the straw on top of the hive and lifting off the hive-cover the bees can be seen and the jar can be filled with syrup without exposing the bees to the temperature outside the hive. When the weather is such that there is no danger of the bees leaving the hive I set up a board in front to protect the entrance from cold winds blowing into the hives.

I have tried several methods of wintering my bees, but like the method described above the best of all.

North Westport, Mass.

A COMBINED HONEY-HOUSE AND HIVE-SHED

BY L. H. COBB

In designing my building I had especially in mind an inexpensive combination of honey-house, hive-shed for shade, and winter protection, an overhead track for handling hives and supers, and cement hive stands. The diagrams are almost self-explanatory, but I will give a few details.

The honey-house, shown in Fig. 1, is 12 feet square, and the extracting platform, shown in *a*, Fig. 1, is $4\frac{1}{2}$ feet wide and 7

feet long. Either screens or doors may be provided between honey-house and hive-sheds if desired.

In this diagram the hive-shed *b* is 7 feet wide, and may be made any length, allowing 6 feet and 6 inches between posts for every three stands. This shed extends south, and takes two rows of hives. The hive-shed *c* extends east, and another may be extended west.

The upper sections of the side of the hive-sheds are hinged so they may be extended at will, and the lower sections are removable. Both of these sections are made in $6\frac{1}{2}$ -foot lengths, extending from center to center of posts, one foot square. *d* in each figure shows the track for the ordinary barndoor hanger. Figures 2 and 3 show forms for the cement stands. At Fig. 2 *a*, a dozen may be made at once. For this form I cut five pieces of 1 x 2, 6 feet and 2 inches long for pieces *a*; two pieces 6 feet 5 inches long for pieces *b*, and eight pieces 18 inches long for pieces *c*. On the upper edge of pieces *c* I nail two pieces of narrow galvanized iron, allowing it to extend over the end one inch, as shown in Fig. 2 *a*. A tack can be driven through these ends into pieces *a*, thus holding the short pieces in place. I nail pieces *b* on the ends of pieces *a* so the spaces will be just 18 x 24 inches. The concrete mixture I prefer is one part cement to two parts sand and two parts cinder. If these are made on the cement floor of the honey-room the floor should be oiled or soaped thoroughly first.

Fig. 3 shows the form for the base of the hive-stand. This form should be made of two-inch material. It should be four inches at the bottom, six at the top, and eight deep inside. It should be six feet long, and should have one end movable. The base for the front of the hive-stands is also the base of the side walls of the hive-shed, and should be just long enough to fit snugly between the square cement-post foundations, or $5\frac{1}{2}$ feet. For the back bases I use partitions of the form, making three blocks 18 inches long.

The houses and sheds may be covered with roofing felt, and cheap lumber used for the frame.

Bee-escapes should be provided where needed, and windows as desired.

This makes a compact arrangement for a medium-sized apiary, and one as convenient as we can conceive of, with protection from sun and bees while working, where there are no boards on the ground to rot, where no toads or mice can find harbors. In hot weather I remove the bottom-boards and put blocks under the corners of the hives to reduce the swarming tendency. I open the sides for shade and ventilation, or close them for protection from the cold. A little heat in the honey-house will keep the temperature above the killing-point during the coldest weather.

Basehor, Kan.

A WINTER'S WORK IN MAKING HIVES

BY A. H. BELL

There is one thing which ought to interest a great many readers of *GLEANINGS*; and that is, the range of work required of one man in connection with the bees and the apiary, such as making hives, supers, frames, nailing up and wiring frames, fastening in foundation, etc.

The past winter I began to make preparation for this year's crop and increase. I make my own hives, supers, frames, etc., just because lumber here is cheap and I can make just as good hives and fixtures as I have ever been able to buy. Jan. 1 I started my combination saw, which is run by a five-horse-power gasoline-engine, and finished up May 1. During that time I hauled all my lumber from Roundup, 11 miles distant, and cut out 135 ten-frame hives, corners halved to nail both ways. I made telescope covers having tar-paper on top, with inside cover and reversible bottom for about 400 ten-frame shallow supers $5\frac{3}{8}$ in. deep, halved at corners, and all hives and supers handholed. I also made 4000 shallow extracting frames and 1500 Hoffman brood-frames, all pierced for wire.

As soon as I had every thing sawed out I moved out the saw to make room; then I began nailing hives first and then supers. Then came the frames, nailing both brood-frames, and extracting at the rate of 800 a day. While wiring I wired 700 extracting frames with two wires each and 600 brood-frames with three wires each. In these frames I put full sheets of foundation, using 400 pounds. I found this somewhat slower work. The best I could do in an hour was to put 80 sheets in the shallow frames. But the whole job ran only 600

sheets per day, while with the brood-frames I averaged 350 per day. This includes imbedding the wire with a spur imbedder, and placing frames in the hives and supers.

The difference in number between extracting and brood frames is due to the fact that I fastened the foundation in extracting-frames with melted wax and a Vandusen wax-fastener, while my brood-frames were quarter-sawed. I used the quarter strip to nail in the foundation. This is a very good way to hold the foundation, but it is a good deal slower.

I then painted every thing three coats of white lead. All this work was done by myself, and May 1 found me ready for a crop of 30,000 pounds of honey.

All the sawing was done on a saw-table of my own make, which is a combination of every thing I could think of.

Elso, Mont.

THE WINTERING PROBLEM

Guesses vs. Facts; the Need of More Complete Data on which to Base Conclusions

BY ARTHUR C. MILLER

The symposium on wintering in *GLEANINGS* for September 1 is interesting, particularly in its graphic illustration of the careless "rule-o'-thumb" method of reaching conclusions prevalent among people not trained to the precise methods of the scientists. Just so long as deductions are made from the faulty, imperfect, and incomplete observations as recorded there, just so long will the practices based thereon fail to bring any thing like uniform results.

Citations of some of the factors not noted by the writers will serve to illustrate the imperfection of the data. One will fail to state thickness of packing or material used; another, the nature of the outer case, whether it is of thick or thin stock, and is virtually air-tight or the contrary, is or is not covered with a water-proof paper; the color, etc. Another, stating one or the other of these, fails to say whether tight covers are over the brood-nest or cushions, and whether the bees have a passage over tops of frames under these or not. A few other items may be enumerated, such as frames side or end to entrance; size of the latter; direction it faces; direction of prevailing winds; any gales or unusual atmospheric conditions; size of colonies (average variable in different years); queens old or young; breeding stop early or late; pollen stores, large or small; na-

ture of stores and abundance; whether bees were overhauled, and frames changed at all after final stores were gathered or supplied; whether the location is subject to thaws or fogs, or the contrary; whether snow on ground was above or below normal most of the winter.

Every one of the foregoing has its bearing on the results; and how few of even the more important ones have been mentioned by the writers! One person attributes his success chiefly to one factor, while the next man lays emphasis on quite a different one; yet as a matter of fact the favorable results are quite as likely to be in *spite* of either item which these men deem so important.

In taking temperature of the interior of the hive, the methods recorded are most imperfect. Putting a thermometer on top of the frames over the cluster gives only one item—namely, the temperature *near* the upper side of the cluster; and *how* near the writers fail to state. Was the cluster close to the top of the frames or even up over them? Or were the bees one, two, or three inches below inch-thick top-bars? Was the cushion laid on the thermometer and frames, or was there an air-space? Was the thermometer read through a pane of glass, or was it taken out? There is but one accurate way to get hive temperatures, and that is to use special thermometers with long stems, placing enough of them in the hive so the temperature of the air near the floor, half way up and at top, both near and distant from cluster, may be secured. Also, temperature of cluster and air directly above it should be obtained. In addition, if chaff or other packing is used, temperature of this over the top of the cluster, and distant from it, is desirable.

The special thermometers are made so the scale to be read is above the hive, and readings can be made without removing the thermometer or disturbing the bees. The readings should be made hourly, both night and day, at least in the fall and spring, while in the really cold weather six times in the twenty-four hours may do.

The "curves" plotted from these readings in hives differently protected can be compared with "curves" from similar data taken in unprotected hives; and with the outdoor temperature a real basis for work will be reached.

Mr. Britton cites his results with glass-topped hives from which he removed the top packing and later substituted black tarred paper. The disastrous results could have been foretold without need of demon-

strating. Moisture was bound to collect on the cold glass, and drop back on to the bees. With an entrance as small as stated, and with eight to twelve inches of packing around the hives, no other result could be secured. The black paper could afford no material relief under such circumstances. His citation of results of colonies in his attic serves to call attention to the fact that bees so placed have their hives surrounded by a temperature of about 50 degrees F. all winter.

As examples of how bees thrive under conditions as opposite as possible to the warm-packing theories, the following may be cited. These I have perhaps referred to before, but they are worth repeating. In the western part of New York two colonies were left to their own devices after having been set, early in the season, inside of large cupboard-like structures which served only to shut off the sun. Four or five entrances about three by twelve inches gave ample circulation of air through the cupboards. The floor of these was 18 inches above the ground. The bees were in ten-frame Langstroth hives set on three-inch rims, and without cover of any sort. When I saw them in March there were visible several fins of comb built above the top-bars, and the bees were sticking up on these and hanging below the frames, just rousing big colonies—plenty of air, to be sure, but no dampness.

The other example is more in Mr. Britton's line. A ten-frame Langstroth hive made of glass, and having a top of wire cloth, was placed on a slat stand about two feet above the ground. Over the hive was placed a box nearly a foot larger each way than the hive. The front end of this box, except for a narrow board at the top, was knocked out. There was no bottom to it. In this hive was a good colony of bees. Shaded on all sides except the front, free circulation of air around it, with cold glass sides and ends, an entrance 14 by one-half inch, and wire-cloth top allowing free draft through it, that colony thrived for three summers and winters until put into another hive. This was in Rhode Island, twenty-eight miles from Mr. Britton's.

The exponents of heavy packing are asked to explain how the bees in these two instances could live, to say nothing of being exceptionally strong and healthy. It is to be hoped that they will not all speak at once. Also, they are requested not to remark that "one swallow does not make a summer," for there were three in this case, and one of them made three summers and—winters.

Four items are pretty definitely shown, however, by the symposium on wintering; namely, the need of dryness, the advantage of some means of preventing condensation above the cluster, the necessity for wind-breaks, and that several hives grouped close together and packed in some "non-conductor" do accumulate heat in the packing above and near the hives. But—yes, *but!* Does the value of the packing lie in keeping the bees warm in *winter*, or in the fall and spring? in the fall, when they are putting the finishing touches on their supplies, and in the spring when breeding? Think twice, please, before you answer. That protection is of advantage from *early* spring until late fall has been pretty conclusively demonstrated; but *what* amount of protection is as yet in dispute. Some want the whole hive, including supers, inside of packed walls; others want merely double walls, and still others think protection about the supers suffices.

Results suggest that colonies in hives wholly protected, even if only by a deep telescope cover or thin outer case, do better from spring until fall than those having only the supers protected. If this is correct, then it is fair to believe that results from fall until spring ("wintering" we call it) are much dependent on fall and spring protection. In other words, safe "wintering" lies more in keeping the bees warm when they are getting ready for cold weather, and when they are getting ready for the harvest, than it does in trying to keep them warm in winter itself.

To summarize: We as yet have only a little and fragmentary knowledge of the real conditions which exist within the hive from fall until spring inclusive. Until we know more about those conditions we can not intelligently devise apparatus to assist the bees. Until we know those facts we are as likely to make and use unnecessary apparatus, costly to construct and costly in labor to use, as we are to omit important assistance. Or, to put it in the language of modernism, without exact knowledge we can not get down to a rational dollar-and-cent basis of beekeeping.

If our experiment stations will use their means and apparatus in obtaining the desired knowledge, they will help us far more than they have yet done. Such research work is in their line, and they can do it much better than the commercial beekeeper, even though the latter has the necessary training. To ask them to abandon their random experimenting and find out facts for us is what we should now do.

Providence, R. I., Sept. 12.

PRODUCERS URGED TO ORGANIZE FOR SELLING THE CROP

BY C. W. POWELL

The price of honey must be governed by the price of other things, p. 478, Aug. 1. Although the bees work for nothing and board themselves, the beekeeper must pay for his feed and other necessities too. Of course, honey at ten cents a pound will sell fast, especially when other things are a hundred per cent higher. When honey and butter both sold for ten cents it was all right; but when butter is forty cents and honey ten, honey and bread will be eaten without butter mostly. I fully agree with Mr. Lathrop, that honey should be sold at home when possible; but the law of supply and demand can not be divorced from the question of distribution, because all the honey and other things can not be produced where consumed nor consumed by the producer. Hence the necessity for distribution, which involves distributors, which cost the consumers of farm products in New York city last year 62 per cent of the retail price of such products. Think of it! The producer and the carrier got only 38 per cent of the price paid by the consumer.

Well, what can be done about it? Just this: Let the producers undertake to distribute for themselves. How? By mutual organization establish agencies in all market centers. Place agents in charge, and put them under bond to guard against loss from dishonesty. Now ship to such agents for distribution on his orders, and he will soon learn just what his market will need, and there will be no overstocking by duplicate ordering and then a scarcity because no one ordered. Let him sell at a price insuring a profit on production after deducting for transportation and distribution.

All kinds of stuff can be sold at a price that will at once double the consumption on account of placing it in the hands of consumers at a price they can afford. Bro. Lathrop's idea about the cheap price of honey making a greater demand for it is like the clothing dealer who could sell his clothing at less than cost because he sold so much of it. To sell honey at ten cents per pound when butter is forty cents would bankrupt any one except a clothing dealer. I have been in a position for over twenty years where I could study the question of distribution, and it is at present the biggest farce on the world's stage. In a certain case Texas farmers offered cabbage on board at shipping point for

40 cts. per hundred—transportation 40 cts. At my door I paid \$2.00 for it (2 cts. per pound). Think of it! Eighty cents to produce and deliver on our tracks, and \$1.20 to take from the car and deliver to my door! Yes, but some say there is a great loss in such stuff. But the loss is principally on account of having to hold the stuff too long in order to get a high price for it. The price is low enough, and with a perfect system of ordering and shipping, it would not be long on our hands. There will be fifteen or twenty cars of watermelons on the track at one time, when the daily demand is perhaps two cars or less, and they stand on the track and rot down in the hot sun, and the shipper not only loses his melons but the freight also. Then perhaps there will be days when there are none in the market at all. Now several dealers order them or they are shipped without orders, and each dealer must depend on guessing what his competitors are going to do, and so miss it badly at times. The producers are advised the market was overstocked, which accounts for the loss to them. The market was overstocked only by a poor system of ordering, and making the price so high that people who want them can't pay the price. We have to pay anywhere from 25 to 50 cents for a good watermelon. Who can afford to keep a family on them at such prices? A land indeed flowing with milk and honey! But who can afford to drink milk at ten cents a quart, or eat honey at 25 to 30 cents per pound, except the rich, and they are few in comparison with those who are not.

A shipment of eight bushels of plums was received in this market by a dealer who wanted three dollars per bushel; but the grocers could not handle them at that price, and six bushels at least were dumped, a dead loss to the *producer* and *consumer*, besides paying freight. All manner of fruits and vegetables are dumped rotten, not because everybody had all he wanted, by any manner of means, but the price was prohibitive.

Producers' associations are formed to increase prices to better the conditions of the producers, without a thought of the consumer who must use their products or there can be no profit. Starving the consumer by taking all his money for one melon when the same money would buy two, and give a good profit to the producer too, is a sin. There are two, and only two, who are vitally concerned—the producer and the consumer, and they are mutually interested, for each must depend on the other. If they will look out for

themselves the question of high cost of living is solved.

The 1911 apple crop is reported the largest ever grown in this country; yet the price never was so high. Why? Do the producer and the consumer know why? *They should.* It would lower the price fifty per cent to consumer, and yet pay a good profit above freight and distribution. Lowering the price of such things would increase the demand correspondingly. Every one should have all the fruits and vegetables he wants, though it be melons, peaches, pears, plums, etc., which are really luxuries. Then there would be a demand for more farmers, fruit-growers, etc., and the nation's blood would be stimulated anew.

Farm products are not the only ones which are manipulated to pay undue profits. You buy a piano. The dealer keeps at least one hundred dollars of your money. A rocking-chair you pay \$5.00 for cost the dealer \$1.50. As staple a thing as carpets are sold at a profit of fifty per cent above the invoice. I have been thinking over this thing for a long time, and am sure that a producers' agency will be much more satisfactory than a buyers' union, because everybody will be reached, whether he wants to or not; and the fewer you have to organize, the better.

I hope you will give this article a place in your pages at an early date, for it seems to me to be of vital present interest to the whole country and all people.

RIPENING HONEY ARTIFICIALLY

The Plan, while Possible under Certain Conditions,
is Not to be Advised Generally

BY W. B. BRAY

I was pleased to see the remarks made by Mr. Ireland, president of the Canterbury Beekeepers' Association, in your issue of May 1, regarding the artificial ripening of honey, and wish to confirm what he says. Mr. Hopkins has had a great deal of experience, and has done much good for the beekeeping industry in this country; but in this one thing I do not think his experience is conclusive. There is more than Mr. Hopkins' reputation as a beekeeper depending on a proper understanding of this subject, and I trust he will not be offended if I help to throw a little further light on the conditions prevailing in New Zealand. For close on to three years I was permanently engaged as a government apiary inspector, and my work took me into every part of New Zealand.

In his article on page 632, Oct. 15, 1911, Mr. Hopkins admits the possibility of another factor in the ripening process than evaporation—namely, a chemical change in the sugars. This would be the continuation of the process of inversion commenced by the bees, by which the proportion of sucrose is gradually reduced. For this reason alone it would be desirable to leave the honey on the hive till later in the season. Though it may be merely a matter of taste, the editor is right when he says that the honey which has the finest aroma is that which is extracted from well-sealed combs. It can be called flavor, aroma, bouquet, body, bite, or any thing else, but the quality is there. I remember extracting some honey which had been on the hive all the winter, and entering it in the show which was held too early for new season's honey to be entered. The judges said that mine was the only sample that had a good flavor.

But it is in the process of evaporation that a good honey can most easily be spoiled if it is attempted artificially, as then it depends entirely on the state of the atmosphere. Every one knows that a certain amount of water is held in suspension in the air. The amount will depend on the nearness to the sea, the nature of the soil, the configuration of the country, the temperature, and the variation between night and day temperature. For instance, in the hottest weather in my own locality the nights are cool and even cold, so that the moisture evaporated during the day is precipitated. A wind off the sea will lose its moisture in crossing a high range of mountains, and become a dry wind. A very rainy district does not necessarily have a humid atmosphere. It will depend, then, on the temperature of the air. In a warm climate, near the sea, and over low-lying land, the air is heavily laden with moisture. The humidity in any one locality may or may not be fairly constant, as a good deal will depend on the lay of the country and the direction of the prevailing winds. In the South Island of New Zealand the air is comparatively dry, and I have known cases where thin honey has been extracted and successfully ripened in tanks. In the North Island, however, the conditions are very humid, particularly in Taranaki and Auckland provinces, on the west and northern coasts respectively.

The evaporation of the surplus moisture of an unripened honey will take place if the humidity of the air is low enough to allow it to absorb more moisture. On the other hand, honey will readily absorb mois-

ture from an overlaid atmosphere. Each beekeeper can test the humidity in his own district by keeping a jar of already well-ripened honey exposed to the air, and watching for the surface to become thin and watery. If a hydrometer is used to test the specific gravity the honey should be well stirred before testing. The beekeeper can then judge for himself as to whether it is safe for him to expose his honey to the air at all. In the humid climate we have in Taranaki and Auckland provinces, I would advise that nothing but well-sealed honey be extracted, and that it be put in air-tight vessels the same day. If it is necessary to store it in a tank, the top should be very close fitting. For the reason given in the second paragraph of this article, I would not advise any one to extract any but fully or three parts sealed combs if he wishes to do justice to his honey and his customers. Honey that is unsealed at the end of the season, and that has been on the hives for some time, is ripe enough to extract.

Mr. Hopkins says he successfully ripened a large crop in tanks in 1883; but I think the conditions must have been exceptional for that locality for that year, or else it was an exceptional locality in the Auckland province. In a government bulletin he has advocated the artificial process of ripening, and numbers of beekeepers have taken it up. The result has been that a lot of soured and fermented honey has gone on the market. The use of the hydrometer will not correct the fault of excessive humidity in the air. The ripest honey (and it is very seldom that all green honey is being extracted) settles in the bottom of the tank; and when a sample is drawn off to be tested with the hydrometer it gives a fairly high specific gravity. Even if the hydrometer is put into the tank, it does not give a proper test, as the thin watery honey is in a layer at the top. It is the last to be drawn off and the first to ferment. Many beekeepers have not bothered to use the hydrometer, thinking it quite sufficient to leave the honey in the tank a week or two, often regardless of the condition it was in when extracted. It is this ignorance of the conditions governing the case that has caused a great deal of the harm done in this country by Mr. Hopkins' advocacy of the artificial method.

In 1910 I acted as judge at the Warkato show (Auckland), and the Hawera show (Taranaki). At the former show I found several entries fermented. The same occurred at the Hawera show; and out of 17 entries in the granulated class only four

were properly ripened. I had' to advise the beekeepers to discontinue the artificial method. The conference of beekeepers' associations in 1910 protested against the method being advised in Bulletin No. 18. In the Auckland salesrooms I have seen honey running out of the tins.

It is possible to ripen honey artificially where the conditions are favorable; but it is questionable whether there is any advantage gained. The late E. W. Alexander was in a favorable locality, and kept 700 colonies in one apiary. He was thus able to keep the extractor going as fast as the new honey came in, and it saved the necessity of providing extra supers. The beekeeper with one apiary can get along well enough with a couple of supers, and extracting only the sealed combs. The beekeeper with out-apiaries would prefer to provide the extra supers, and attend more to the putting-on of supers while the honey-flow lasted. The extracting is done afterward, and the one job is made of it at each yard. During the honey-flow the bees secrete wax in abundance, and are more contented if able to use it up in sealing the combs. The work of evaporation is carried on all night, and all together it is doubtful whether the amount of the crop is increased at all by extracting the green honey.

Salt is a substance which readily absorbs moisture, and it is safe to say that, where salt becomes damp, honey will do the same. I have had no experience with sections; but I should say that a good plan to prevent them from "weeping" would be to place a box of unslaked lime in the room where they are stored. It would keep the air dry.

Devauchelles Bay, N. Z.

THE NEW CAGE CANDY CALLED "FONDANT" BY CANDY-MAKERS

BY E. C. NEWELL

The candy for bee-cages is nothing but fondant that is used in high-grade candies. The best recipe is this: Granulated sugar, 10 lbs.; glucose, $2\frac{1}{2}$ lbs.; water, $2\frac{1}{2}$ quarts.

Put the water in the kettle; add the sugar. When it boils put a cover on for five minutes; then remove and put thermometer in the kettle. Heat the glucose; and when the boiling sugar reaches 235, add the glucose and cook to 242 in winter, 245 in summer. When cool enough to put the finger in, it must be creamed by stirring with a spatula. When creamed let it

stand a few minutes with a damp cloth over it. It will begin to harden, and must then be broken up and kneaded until soft. It then will keep indefinitely in a stone jar with a damp cloth over the top.

Two teaspoonfuls of cream of tartar can be used in place of glucose, but it makes an inferior article.

The cover is put on the kettle to be sure that the steam dissolves every grain of sugar; as a single grain, or changing the spatula from another batch, if you are stirring two, will make it granulate instead of creaming. A sudden jar to the kettle will sometimes have the same effect. Do not stir while boiling.

Commercial glucose is the article. Corn syrup is an adulterated glucose. Glucose comes in two forms—heavy and light, the first in ten-gallon kegs, the latter in barrels, and can not be bought here in the East in less quantities unless you know some confectioner who will let you have it.

While the fondant is warm it can be pressed into a frame and hung directly in the hive.

I do not believe in feeding in any but the Doolittle way (full combs of honey), but have had in New Hampshire frames filled with comb as the fondant was eaten away in the winter time in the cellar. Cane sugar is absolutely essential. If your fondant fails to cream properly you may know you have got more or less beet sugar.

I am not a confectioner, but have made candy for home consumption, buying glucose in original packages and sugar by the barrel; chocolate, 100 lbs. a year, etc. I spoiled 100 lbs. of fondant before I found out the last wrinkle, and a confectioner's supply house put me on to that.

Woburn, Mass., Sept. 5.

Plain Sections Easy to Handle

It has been stated that plain sections are harder to handle than the beeway; but I can not agree to that, for I have taken off over 1500 of them, and not one of them is bruised. I used beeway sections for over thirty years without separators, and I consider them much harder to handle, and also much harder to clean. I will use only plain sections in the future.

WIRING DANZENBAKER BROOD-FRAMES.

When wiring Danzenbaker brood-frames I cut the wire in exact lengths, which is easily done if some one else holds the end and throws it in the box after it coils up. In this shape the wire seldom gets tangled if one is careful to pick them up right. I drive the rivet back a little, put the wire around it, give a couple of twists, run it through the hole, then up to the hole next to the top-bar, finally finishing at the rivet on the other end-bar. With a small pair of pliers I hold the end, draw on the wire as though cording an old-fashioned bed, and when tight I wrap it around the rivet and drive both rivets back into place.

Clear Springs, Md.

C. M. HICKS.

Heads of Grain from Different Fields

Honey-house Bee-escape

I have a honey-house bee-escape that has never failed us. It is made up of a series of wire-cloth cones inserted in a 1½-inch space on top of the window-screen, with a double set of flat wooden escapes on the outside, which is covered with wire cloth. I have yet to see the first bee that has returned by the way it came out, and it lets them out by the droves.

J. E. THOMPSON.

Halfway Tree, Jamaica, B. W. I.

[This looks as though it might be a good honey-house bee-escape. The additional screen over the top of the cones would prevent the bees from going back. The only objection we can see to it is that it is complicated to make.—ED.]

Honey from Second Crop of Clovers

At present bees are working on the second crop of red, white, and alsike clover, and goldenrod. They are giving more trouble about swarming than at any time this season, although I have put supers on every colony.

NEWLY INTRODUCED QUEEN LAYS AMONG QUEEN-CELLS.

I let a laying queen run into a colony for fun, with queen-cells ready to hatch, and found her next day laying on combs among the queen-cells.

Derby, Vt., Aug. 25.

NEWELL H. WILSON.

[The second crop of red clover has yielded more this year than for some seasons back. It should be remembered that the corolla tubes of the second crop of red clover are much shorter than those of the first crop, provided it has not been too dry when it comes into bloom.

Letting loose a laying queen into a hive having queen-cells sealed over, would, in our opinion, nine times out of ten—yes, ninety-nine times out of a hundred, prove a failure. That it worked in your case was the exception that proved the rule. The hardest colony, in our experience, to introduce a queen to is one that has queen-cells pretty well advanced—especially those that are ripe and ready to give off a virgin.—ED.]

Eggs Hatching by Artificial Heat

I think Dr. Miller, page 301, May 15, will find that the eggs of bees, if kept continuously warm, will hatch without the presence of the bees. I very well remember removing from the supers a number of sections in which the queen had started to lay. For want of a better place they were carried into the kitchen temporarily. At that time we were sweltering in the midst of a hot wave. A few days later, in removing the sections I was surprised to find very young worker and drone larvae instead of the eggs.

J. FORD SEMPERS.

Aikin, Md.

[We have had other reports from beekeepers who find that eggs of queens, if the temperature is right, will hatch without the presence of bees.—Ed.]

Bees a Feature of the Hamilton County Fair

The Hamilton County Agricultural Fair at the Carthage fairgrounds was a success in every detail to all concerned. The horse races, fine poultry, hogs, cattle, the bees, and balloon ascension drew big crowds the four days of its duration. The weather was fine, which accounted for the large attendance of city and country folk alike. City folk appreciate the country fairs more from year to year. They realize that the farm and suburban gardens must go hand in hand with the manufacturing interests. Electric cars and automobiles bring the city and country nearer to each other than in former years when people relied mostly on omnibuses and road wagons. In no line of rural production has science done more than in the keeping of the honeybee. "There is nothing at a county fair that the visitors are more interested in than in live bees in observatory hives." This is the opinion of Mr. J. G. Creighton, who had charge of the bees, honey, wax, honey vinegar, and bee-supplies at the Hamilton Co. fair. Mr. Creighton received a first prize on the four first-named articles; Mr. Charles H. Weber first prize on bee-supplies; Mr. Wm. Schmees second prize on live bees. Mr. John J. Leonard won a second prize on comb and extracted honey. Mr. Creighton is quite an enthusiast on county fairs. He resides at Harrison, O. Mr. Charles H. Weber and Mr. Wm. Schmees are from Cincinnati. Mr. Leonard makes his home in Elmwood, O.

HENRY REDDERT, Sec.

Too High a Price Makes Honey a Luxury

I heartily agree with Harry Lathrop, Aug. 1, p. 478. I have followed the same plan of selling honey direct to users, at a low price, with the idea of making it a popular food. Working for a higher price strikes me as a class luxury. I do not know that it can generally be done until there are more beekeepers.

Bergville, Minn.

A. B. WHITE.

Large Number of Swarms Captured in Boxes

On p. 466, Aug. 1, A. I. Root stated that there must have been a terrible stampede of runaway swarms in this part of the section. Now, though I have been here only since April 4 I have seen more than 75 swarms captured in the same way, and I also know of an old gentleman who caught over a hundred in boxes in this part of the section.

Whittier, Cal.

H. D. H.

A Few More Instances of Chickens Eating Live Worker Bees

We had one chicken about five or six years ago that we found eating bees from our hives more than once, picking them up in a hurry—live bees, too. However, it seems to be a rare occurrence. Tazewell, Tenn. HENRY B. SOUTHERN, JR.

I live in the city, and have bees and chickens together on one lot. I discovered one of my largest Plymouth Rock hens eating live bees off the alighting-board, and I watched her to be sure. Well, she did not eat any more. Lima, Ohio.

MRS. J. A. MOONEY.

I have kept bees for 30 years and chickens for a longer time, but have never kept both in the same yard; but the fowls were liberated each day for a run in the beeyard to eat grass. In 1897 I had a half-grown grade cockerel that would rush to the hives as soon as liberated, and eat live worker bees with as much relish as he would eat corn; but, like Mr. Gray's early riser, he died young, and that is the only case of which I have positive knowledge.

A Dayton friend, who kept both in the same yard, had two first-prize cocks stung to death last year.

The trouble that I would fear would be their eating young queens that are out getting their location before making their mating flight.

Dayton, O. J. W. NICHOLS.

I had two stands of bees in my poultry lot last summer, and they were almost ruined by the poultry. The chickens would stand by the hive and watch the bees, and pick them up as fast as they appeared. They were watching for bees all the time. Finally I separated the bees from the chickens; then the bees soon became strong. This year I have increased my apiary from 2 to 8 colonies. The poultry-yard is about 4 ft. to the rear of the bees; and I noticed yesterday, as soon as a bee crossed the poultry-yard the chickens were right after it. I saw them catch half a dozen or more. I think the reason for the hens eating the bees is this: Where poultry have but a small yard they are not able to get many insects, and unless you feed them plenty of meat they begin to catch drones, eat the head of crippled bees, and finally they develop an appetite for bees, the same as a man does for tobacco. After I penned the poultry from the bees they would just stand up close to the fence and watch the bees. You may think I am exaggerating; but I shall be pleased to prove it to any one who will take the trouble to call on me. I am satisfied that, if you will pen 40 or 50 chickens in a small lot with two stands of bees, the chickens will eventually ruin them.

Columbus, O., Sept. 14. S. S. SNYDER.

For a dozen years I have had bees and chickens occupying the same territory in an apple orchard. Two years ago in the spring, during fruit bloom, I noticed a Wyandot hen busy at the entrance of a hive picking up, killing, and then swallowing bees. When I would scare her from one hive she would go to another, and kept on eating bees until she had her fill. The next day she was at it again, when I caught her and sent her to market.

A few days later I found another one doing the same thing; then I began to take notice. I found the combs crowded with brood. We were having some real chilly nights. Each morning the bees would bring out some chilled brood that was white and tender and drop some of it around the entrances. This made a sweet morsel for the hen. She soon learned where to find it; and while looking for this, bees loaded with pollen would alight right there where she was picking up "grub," and she turned her attention to them. By close and persistent watching I found that the chickens ate no bees except those loaded with pollen. Except this one time, chickens have never bothered my bees.

"LOSING" LAYING WORKERS.

I had a very bad case of laying workers a few weeks ago. When I discovered it some of the combs were nearly full of capped drone brood, and there were hundreds of little insignificant drones

in the hive. Many cells had half a dozen or more eggs in them. After failing to introduce a queen, and having some queen-cells torn down, the following plan succeeded admirably: I took out one comb and placed it in an empty hive. I then shook off every bee into this hive, and placed the combs back in the old hive after shaving off the heads of the unhatched drones. Then I placed the hive with the bees about 40 feet away, and left it until next morning. By this time most of the bees had returned to the old stand. I shook off the remaining bees, closed that hive, and returned the one comb to its original place, and introduced a queen by the usual candy route, which was readily accepted. The layers and most of the drones failed to find their way back, while the workers all came back home.

Liberty, Tenn., Aug. 28.

W. P. BANKS.

The One-hole Feeder Applied to the Alexander Feeder

The drawing shows my method of stimulative feeding with a one-hole feeder. Should I care to feed for drawing out comb, or perhaps making up for a shortage of stores in the fall, I remove the one-hole feeder, putting on the regular block, and use the feeder in the regular way.

The first day I use the one-hole feeder I pour some syrup in the Alexander feeder, and then put

on the one-hole feeder at once. Of course, I move the piece of screen and also the cleat, which is nailed near the end.

This feeder is an improvement over either the Boardman or pepper-can feeder in more ways than one. It works perfectly, and prevents robbing entirely. I feed $\frac{1}{2}$ pint daily (two parts water and one part sugar).

St. Louis, Mo., May 6. HARRISON FISBECH.

[An arrangement of this kind can be used where it is desired to practice slow feeding with the Alexander feeder. If one has already attached to his hives such feeders, or the Boardman, one or two holes can be used in connection very nicely. In our own practice we prefer the regular entrance Boardman feeder, and have little or no trouble from robbing, particularly when the bees are not allowed to take the feed any faster than they can take it from one or two holes.—Ed.]

The Way I Make a Success with Bees

Since Walter S. Powder has opened the subject along the line of beekeeping that I have practiced, page 378, June 15, it has encouraged me to tell how I have made a little money out of a few bees I keep. It is all right to talk about keeping bees for the pleasure there is in it; but how many of us can afford to do so when we have a family to support? We all love a little recreation; but how nicer it is when we get some returns from it too!

In the first place, I get my bees to the swarming point about the time the honey-flow begins, then I proceed as follows. I take an empty hive body with inch starters; select two frames with brood in all stages, making sure that I do not have the queen on either one; place the queen-excluding board on the hive, then put the empty body on top with the two combs of brood in it and one frame with an inch starter between. By this change the bees get into the upper story immediately; and as the two frames are spread apart the bees will cluster between them and begin comb-building at once. In a few days I spread the

brood again, putting another frame with an inch starter between. I find that I can produce much more honey this way, as the more the bees are divided the less comb they can build. This gives them the entire hive body to cluster in, and prevents swarming to a great extent.

The honey is just as good as that which is secured in sections, and so far as the disposing of it is concerned I find it easier than selling section honey. For instance, I cut out about two and a half pounds, put it in a bucket, and then pour over it enough extracted honey to make five pounds.

When I ask a customer if she wants some honey she may say that she gets it from the grocer on the corner. I always insist, however, that she get a spoon and taste the honey. It does taste "just like that we used to get on the farm years ago," and she takes a bucket. I can dispose of all the honey I produce, and much more; and the joke of it all is that I get 25 cents a pound while my neighbors get only 20 cents for their section honey.

I will admit that this plan will not work where one has no home market; but I can see no place in the central part of the United States where one can not build up a home trade for all he can produce. Sometimes a beekeeper thinks it necessary to ship his honey away to a large market, when, if he would only try, he could dispose of it all at home.

The Advantage of Blending Different Kinds of Honey for Market

I find that properly blended honey gives much better satisfaction than most kinds alone. Even our very fine sourwood honey gets more body by blending with honey from winter huckleberry, or with that from cotton or coreopsis, either of which is nearly as clear as water. The two latter do not have quite enough of the distinctive honey flavor. Our early honeys here in Northwest Georgia are nearly all dark and strong, with the distinctive honey flavor; but that from persimmon bloom, and from the hickory honey-dew, are of a dead sweet. Blending properly brings them right.

We have also a bitter honey from the bitter oak. This is thick and rich, and blends well with a thin honey, and some strong kind, using about one-fourth of the bitter honey. Poplar is given more honey flavor by a mixture of other kinds.

I find that many people when tasting honey expect the flavor that the honey had that they used to get out of grandfather's gums; and if they don't they think that it is manufactured honey. If they can get a little of the old taste they are satisfied. Many do not know that there are as many kinds of honey as there are kinds of flowers and sources of honey-dew that it comes from. The kind that they know is the kind that is produced in their locality at a certain time, and taken out at the only time that grandfather used to "rob" his beegums.

For my own use I like to keep a few kinds as nearly pure as practicable; but I find that, for the market, it pays to blend almost any kind with something else. I have lately been selling honey for the principal honey dealer of Chattanooga, and he was quick to see the advantages of my blending.

Kensington, Ga., July 22. C. W. LUDLOW.

Scored Cylinder of Gasoline-engine

After standing for some time idle in a warm place I started my gasoline-engine without cleaning the cylinder. The piston and cylinder cut on the under side, but not so as to cause a leak. What shall I do to stop this cutting? SUBSCRIBER.

[Your trouble must be due to a poor grade of cylinder oil. If you use a good oil the piston should not cut the cylinder, no matter how long you leave it in a warm place without cleaning it. Of course, if it were left a year or more in a damp place, and the cylinder had not been thoroughly oiled at the time it was laid away, rusting might set in so that you would have to take the piston out and thoroughly clean it and the cylinder with kerosene, then supply plenty of lubrication when you put it back. Be sure not to use any thing but the highest grade of gas-engine cylinder oil. Do not use steam-cylinder oil. If your piston keeps on cutting, there may be some foreign matter, such

as dust or grit, in the cylinder, or your lubricating oil may not be good. Possibly the wrist-pin has worked loose, and is scoring the cylinder.—ED.]

Outside Cases for One and Two Hives

As my bees have not wintered well in my basement, which is too warm, I thought to try it outdoors; so I have made the following arrangements, and I should like to hear through the columns of GLEANINGS what yourself and some of those who have wintered outdoors think of my chances of wintering the way I am going to. I have made the case of lap siding, four boards in height, and large enough to hold four inches of planer shavings on each side, and three inches on the front, with about six or eight inches on top; then I have made a cap of inch lumber and covered it with two-ply roofing. This telescope over the case two inches. I have made 40 cases to hold one hive each, and 50 to hold two hives each. For the entrance I have entrance blocks out of 1x3 by cutting out a piece $\frac{3}{4}$ x5 on the flat side of the 1x3, the same to lie down on the entrance on the flat side. My bee-yard is well protected from all cold winds. I have a nice beecellar under the residence, but it is too warm. I have a hot-water plant in the basement, and the beecellar is partitioned off with stone from the rest; but there are two sets of radiator pipes that go through the wall into the beecellar. I have had a window under the porch wide open all winter, but could not keep it cool enough. I am going to try 25 colonies in the basement, and the rest outdoors.

Mora, Minn., Sept. 4.

C. H. HARLAN.

[It will doubtless depend a good deal upon the winter as to whether your colonies will do best outside or in the cellar, although if you have trouble in keeping the temperature of your cellar low enough we presume the colonies would winter out of doors better.]

You have gone to considerable expense, probably, in making these cases. You could have saved somewhat by making your cases to hold four colonies, and also conserved the heat by so doing. When outside cases are built in this fashion it is customary to put in four colonies rather than two or only one.—ED.]

Full Sheets of Foundation in Sections no Longer Wanted

For some time I have been experimenting with starters in sections; and instead of full sheets or short starters at top and bottom I have found that a certain shape of top starter with a bottom starter (*a la* Miller), and side starters similar to bottom ones, have given the best results.

In over 500 sections, not one comb was fastened in the least to the fence, as is so often the case with full sheets. I never used a split section. I have one section with every cell except three filled and capped all around next to the wood, and only one pop-hole in it, and this was when there was plenty of room above for storage. I am done with full sheets.

A Way to Catch Skunks without Endangering Other Animals

A few years ago my attention was attracted by the ground being smooth in front of a few of my hives; and after looking closely I satisfied myself that it was a skunk's work, by an occasional track in the fresh dirt. The next thing was to find how I could catch him and not catch my neighbor's cat or dog. Well, I took a small barrel, drove a nail on each side near the center, and hung it by the nails resting in notches in two stakes in the ground. Then I dug out the ground between the stakes, so the barrel could swing down in an upright position. I tipped the barrel over endwise, and put some old scraps of meat or honey in the back end.

When the skunk walks into the barrel it will tip up, and he can not get out. In the morning the barrel can be carried away and tipped down. The skunk will walk out slowly, and you can shoot him or drown him. Skunks will make no smell in the barrel unless molested. I have caught several in this way.

Our Homes

A. I. ROOT

Grieve not the Holy Spirit of God, whereby ye are sealed unto the day of redemption.—Eph. 4:30.

There is a way which seemeth right unto a man; but the end thereof are the ways of death.—Prov. 14:12.

Strait is the gate, and narrow is the way, which leadeth unto life; and few there be which find it.—Matt. 7:14.

About thirty years ago we planned and built a commodious two-story brick house; and this comparatively good-sized brick house was all needed for Mrs. Root and myself and the five children. But one by one the children were married, and now all have homes of their own; and therefore the responsibility devolved on Mrs. Root to look after and care for that domicile with its many rooms upstairs and downstairs. We could not well rent a part of it to somebody else, because it was not planned nor built with that end in view; and when people get to be past threescore and ten they usually get to be a little tenacious about their own ways, and places of leaving things. We have always devoutly believed in having "a place for every thing, and having every thing in its place;" and this is easily managed when there is nobody else on the premises to misplace and disturb the order of things. Myself and the children have suggested to Mrs. Root to lock up the rooms she does not need, and thus make our home a small one; but the good woman declares she can not do that—that is, so long as she occupies the premises and is responsible, there must be a regular house-cleaning every spring and fall, from cellar to garret, and then from garret to cellar; and I guess she is not far from right. This periodical house-cleaning brings to light things misplaced or forgotten, and enables us to hand over the things we no longer need to some of the good neighbors as well as relatives who would be very glad of them. And while I think of it, let me urge elderly people like ourselves to look over their effects; and as they come across these things they no longer need, distribute them among the younger friends who *do* need them—children's toys, for instance. What is the use of preserving them after the children are grown up and gone? If the grandchildren have more modern playthings, make the children of poor families happy by presenting them the out-of-date relics of childhood. Get rid of stuff stowed away, without waiting until you are dead and gone.

Well, Mrs. Root talked much about a little home that she could easily look after, such as we are just now planning. She

thinks a modern bungalow would suit her best, because she is tired of climbing up and down stairs, which she has done thousands and thousands of times during her life. Just think of a little home with every thing on one floor, with a little kitchen just large enough, and no more; likewise a dining-room and pantry, and a bedroom not far away, with modern bathroom, closets, etc., making it easy to take the daily sponge bath I have talked so much about.

In our town at present we have gas for fuel that is even cheaper than wood or coal, to say nothing of leaving no ashes, heavy wood to bring in, kindlings, etc. Of course we want an open fireplace; but this is also easily managed by the modern gas people. We have our own electric plant, so there is no more fussing with lamps and chimneys. We want a good up-to-date cistern, and want it well down in the ground so as to keep the water cool. Perhaps you will catch on to the idea that Mrs. Root is planning to do her own work, without the assistance of a hired girl (or anybody else) as long as possible. I do not mean to be disrespectful to the *good* girls and women who help others in their homes; but we all recognize, or should do so, that elderly people have their own ways and habits, and therefore, if I mistake not, they are usually happier to have a great part of the day to themselves. But please do not understand that Mrs. Root is ever annoyed by the good children and almost a dozen grandchildren who trip in and out at almost all hours of the day. The grandchildren especially are the delight and joy of her life.

Now, I am thus going into details because there are many elderly people who are reading these Home papers; and I frequently get letters of late from those who have followed me in *Our Homes* for almost forty years. By the way, when the Holy Spirit called me to open this department in our journal, and to head it "*Our Homes*," I can not recall just *why* I chose that title. At any rate, it is quite fitting that I should take up the matter, in this department of a "home" built of wood and brick and cement. We want the roof of this bungalow made of slate in order that we may have the purest and best drinking water. As we are now using gas instead of coal in our factory, there will be less smoke to settle on the roof and spoil the rain water. I have several times discussed

sanitary cisterns in times past, and I may take it up again before I get through "building our bungalow."

You may wonder what all the above has to do with the three texts I have chosen. Well, we are just getting around to it. In planning our new little home we decided, or at least *I* did, that we wanted it very near to the five homes where our children have *their* homes near each other. The most available site was where a tenement house has stood for something over twenty years. This house was built on the old-fashioned plan of having it close up to the street. Were it not for this, Mrs. Root thought that the old house fixed over would do very well, say during the remainder of our lives. But the young folks all put in a big protest. First, they would not consent that their father and mother should live in any such "domicil," even when fixed over; secondly, they are planning a nice street, and this one little house would spoil the effect of all the other houses on that street, and so the house in question would have to be moved back or moved away entirely. The three other dwellings already on this street are all back a uniform distance, with nice green lawns in front, and therefore this house *must* be moved back. I said if it were to be moved back it should be moved further away, and have our bungalow take its place, located back on a line with the three other homes. Now, let me digress a little right here.

The past month or six weeks have been one of the *happiest* periods of my life; and as I have said several times before, this was because it was one of the *busiest* times of my life. In planning for the bungalow there were errands innumerable back and forth from the factory to the new building. With my little electric automobile which I have before mentioned, I can get around almost anywhere, and go with the speed of the wind, or even faster, when I am in a hurry. It will go backward or forward, turn about in a narrow space, and, with the practice I have had with it, it seems almost like bringing to pass the dreams pictured in that old book the *Arabian Nights*. Mrs. Root tells all the children to call on me any time, for nothing makes me happier than running on errands with the little auto. With it I can bring quite a little load of cement, doors, windows, small bundles of lumber, etc.

Well, another thing that has made me particularly happy is the presence of the Holy Spirit; and my constant prayer, both night and day, has been, to use the language of that beautiful text, "Grieve not

the Holy Spirit." I wonder how many of the world know what a precious thing it is to feel the *presence* of that Holy Spirit every day of their lives; or, in other words, to feel, even through the busy rush of business, the words, "Well done, thou good and faithful servant." In an establishment like ours, where there are usually two hundred hands or more employed, a lot of them outdoors as well as indoors, there are frequent misunderstandings. Somebody's feelings have been hurt by foolish gossip. Another one has been reprov'd when he was not at fault. Somebody has not had his wages advanced when they ought to have been; and somebody occasionally, on the other hand, idles away his time instead of attending to his own proper task. Well, when I am feeling real well, as I do now, it is a pleasure to me to listen to their particular trials and to help right little wrongs. When I can get some one to take up his task with renewed courage, say with a *glad* heart instead of a *sad* one, then I feel that voice of the Holy Spirit.

Now, the above would look as if I must be a "pretty good old man," would it not? But I want to quote from my father's favorite text once more: "He knoweth our frame that we are but dust." Notwithstanding what I have been telling you, every little while I am obliged to remember that I *am* but dust after all; and not only that, but at times I am *exceedingly* "dusty."

After the matter had been thrashed over, and Mrs. Root and I had consented to move the house away and not spoil the street, and after the ground had been carefully staked off where the house should be located, so as to be ready to begin on the cellar, some of the younger ones wanted it *further* away; and after we had spent considerable time in surveying and placing the stakes, we pulled them up and set them again; and three good stout men commenced digging out the cellar. After about an hour's work, however, the young folks *again* wanted the location changed. I objected to so much waste of time and labor. One of the boys said, "Why, father, how much does throwing out fifty cents' worth of dirt, and putting it back again, amount to compared with the future appearance of the street?"

Reluctantly I told the men to stop work. Then three of my sons-in-law, with their tapelines and stakes, commenced planning and surveying. I grumbled about having the men stand still, for it always vexes me to have a gang of men, right in the middle

of a nice day, wait for somebody to give orders.

By the way, it just now occurs to me that I want to tell a little story right along in this line. My department has not had much to say about bee culture of late; but this is a *bee* story. You listen and see if you do not agree that it is a "bee story!" Our factory usually shuts down on Saturday afternoons. We have four good stout horses, but they are during the week so busy with the factory work that it upsets them to stop work. Well, I had planned to have some grading done on one particular Saturday afternoon. Four horses and six big stout men were on hand to do the job. Before any thing could be done, a few furrows had to be plowed, and I was hurrying to get the plow started. But a ring in the doubletree broke before the plow team had hardly made a start. I rushed off with my automobile, grabbed a ring out of the toolhouse, and got them started. Then somebody wanted to talk with the driver. Meanwhile the four horses and six men were standing idle, and I was very anxious to get the job done before night. While I was busy on some other errand with my auto, something happened *again*. Two teams and six men were still loafing. I rushed up and inquired, "Why, what is the matter *now*?"

"Yellowjackets," was the reply.

Then they pointed to a pile of deep grass where a big nest was turned out with about a bushel (?) of jackets on the ground and in the air. Some of them laughed, thinking they had got A. I. Root "up a stump" *sure*. I considered the dilemma for about fifteen seconds. Then I stooped down and put my pants inside of my stockings. I had on light low shoes, for it was a warm day. I did not wait for a veil or for a smoker, for I was impatient with the delays we had already endured. I just "waded in." There were some cheers as I stamped those yellowjackets into the soft dirt and piled sods over the nest,* tramp-

* Here is a point you will bear in mind: If you wish to destroy a nest of bumble-bees, hornets, or yellowjackets, break up their home as speedily as possible, and get every particle of the comb containing larvae out of sight and covered up. These insects fight for their children and their young just exactly as a sitting hen fights for her chicks. In fact, a swarm of bees that has got to stinging every thing everywhere may be quieted almost at once by moving their hives away—putting them in the cellar, for instance. They fight to defend their home. When their home is gone or obliterated they have nothing to fight for. They are lost and demoralized; therefore when you are fighting insects get every trace of their loved ones, especially their babies, out of sight as soon as possible. These yellowjackets would gather in great numbers about the smallest scrap of their nest left uncovered; then I got plenty of soft dirt and piled it over every vestige of their domicile, and tramped it down. After this

ing them down and killing the furious insects in the air as fast as I could. I did not get stung at all on my hands or face; but there was a little bit of "zone" where my pants did not reach quite to my shoe-top. The hissing jackets, crazy with rage, discovered this narrow break in my "armor," and planted stings by the dozens or may be hundreds wherever they could reach through my thin stockings and enable their stings to "catch on." I had not been stung enough of late years to be as thoroughly immune to bee-poison as I used to be, and my ankles swelled a little; but they troubled me later on, more by burning and itching rather than by the swelling. In ten minutes the team was started, the men were at work, and the grading was finished before night. The above illustrates why I get impatient when work is "blocked." I will now go on with my story. I dread telling the rest of it; in fact, I have been putting it off as long as I could by talking about something else. Well, here goes:

Three bright young men, clean men in the prime of life, were busy, as I have told you, with tapelines, chalklines, hatchet, and stakes. I pleaded and begged with them to let me go on with my work in my own way. I think, in fact, I told Mrs. Root that very morning I would give a *hundred dollars* if I could have my own way that forenoon instead of being obliged to give up to the ideas of somebody else. I *finally* decided I could not wait any longer, and I tried, pleasantly, to tell my good friends they would have to excuse me if I declined to adopt any more changes. I shall not soon forget the pained look that came into their bright faces as they dropped every thing and went away looking sad and sober. I told the workmen they might go on with their digging, and went over home and said to Mrs. Root, "Sue, for the first time in my life I have been rude with my three sons-in-law."

The words were hardly out of my mouth before Blue Eyes and her good husband came in at the open door laughing. I rather think they overheard my remark; for they both replied in almost the same breath, "Why, no; you have not, father. We will give way, of course; but we are sure you will regret it when you come to think it over more."

The Christian spirit they showed rebuked me again. But I was so sure I was right that I decided to let the men go ahead digging.

all fight was taken out of them, and they were soon scattered and gone.

Here comes in the second one of my texts. For fully two hours Satan kept persuading me I had done exactly the *right* thing by "setting my foot down." We very soon had a board meeting on some other matters, and toward the close of it the matter of the cellar came up again; but I said I preferred not to have any changes made. Meanwhile one of my sons-in-law was making a map of the street; but I was still too headstrong to look at it. It was time for my daily nap just before dinner. Oh, what a boon these refreshing naps are to me just before noon, and again just before sunset! This beautiful little electric automobile, in order to do its work well, and get up speed at the word of command, must have its *storage battery* "charged" at least once or twice every day. If this is neglected, instead of going like the wind, it just "crawls" at a snail's pace. Well, my splendid health is in like manner kept up by these daily naps. I started to go over to the house to lie down, and then discovered it would be of no use. *The Holy Spirit had deserted me.* I had "grieved it away" by being rude to these kind friends of mine. Just as I was crossing the street Ernest (he is not only Ernest in name, but "earnest" in spirit and has always been so) came along and said, "Why, father, they say you have started those men *digging* again. Arthur has made a nice plan of the whole street. You surely will come over and *look* at it, will you not?"

At first I started to tell him I did not wish to look at it, and that I did not want any more changes. But there was no resisting the honest enthusiasm he showed in having me get *exactly right* before I "went ahead." I went over and looked at the drawings. I saw the point the boys were making, clearer than ever before, and then I went back to where the three men had been throwing out dirt; and it seemed to me they had thrown out an *astonishing* lot of it, in just two or three hours. I confess it *was* humiliating to stop them once more, and tell them that, when we got time, the dirt would all have to be put back where it came from. But it was the *only* way—the only road out of the trouble; and that road is described in our concluding text—"Strait is the gate and narrow is the way that leadeth unto life."

You doubtless have heard it said that relations can never agree. Think of the wicked and foolish jokes that have been said about "mothers-in-law"! Now, if you wish to have the "peace of God" constantly with you—that peace which "passeth

all understanding"—let me beg of you to avoid family quarrels; and especially make it the rule of your life to be kind and gentle in all your dealings with the man or woman who married your daughter or your son. *Whatever* you do, avoid difficulties and disagreements of *this* kind.

Let me go over briefly a little story I have told several times before. At one of the York State conventions they were discussing the matter of bees troubling the neighbors. One man got up and said a very rich man moved into his neighborhood, and commenced to put in some extensive improvements. Very soon he decided that the large apiary belonging to the speaker was a nuisance to the neighborhood, and would have to be moved away. Litigation was started, and there was going to be expensive warfare on both sides. The speaker hesitated right here, and when somebody asked him how it came out he replied, "It did not come out. This man had a daughter and I had a son; and while we were planning for a big lawsuit those two 'fool kids' took it into their heads to 'fall in love' with each other. We two fathers stormed and remonstrated; but that only made matters worse. Nothing would pacify the youngsters until we two shook hands across the 'bloody chasm' and dropped all litigation. He finally decided the bees did not make any bother worth mentioning, and I for my part found out that he was a real nice and neighborly man when I came to get really well acquainted with him."

Now, then, friends, one of the morals of my story to-day is that the ties of relationship should be held most sacred.* Let me use the beautiful text I quoted in closing my Home papers in the previous issue:

Let there be no strife between me and thee,
... for we be brethren.

* The place in the land where those men worked so hard on that hot summer day in digging out the cellar has been filled up, and we have tried to put the dirt back where it came from; but in spite of all we can do, the traces remain to disfigure more or less the green landscape; and in a like manner the memory of giving way to an impatient impulse remains. Not only my three relatives but the three men who were digging, and some others who stood around, got a glimpse of A. I. Root that did not exactly accord with his teachings and admonitions on these pages. As I look back I feel as if I would give a big lot if that little incident had never happened, or if I could *forget* it ever happened.

A KIND WORD BRIEFLY EXPRESSED.

If A. I. Root is alive, thank him for his kindly treatment of me 22 years ago.

Seattle, Wash., Aug. 14.

R. Z. FAHS.

[Many thanks, my good friend; and although I can not recall any thing about what you refer to, I am glad to think that I was enabled to lend a helping hand to some child of humanity 22 years ago.]

Temperance

OUR FRIEND DOOLITTLE TURNS THE LIME-LIGHT ON TO ONE PHASE OF THE LIQUOR-TRAFFIC.

Mr. A. I. Root:—When I read the enclosed, clipped from the Aug. 15th issue of *GLEANINGS*, I was amazed at your putting the matter up to Woodrow Wilson. You know he can not come out for the annihilation of the liquor traffic any more than can Taft or Roosevelt without having his political head cut off. How can he, and yet remain at the head of a political party which, if it comes into power, becomes a part of the United States government, which now takes \$1.10 tax on every gallon of whisky, and \$1.00 on every barrel of beer made? Now, if, when the government received the taxes on these gallons and barrels, none were sold, that would be the end of the revenue accruing; so in order that it may be sold, the government persuades men to sell it, by making it a *lawful business* by way of a license for which the sellers again give a revenue by paying \$25.00 for the same. Now don't you see that, for the sake of this revenue by way of tax and license, the party in power is pushing the sale of liquor as fast and as hard as it can? And after the seller has paid this tax and license, he in turn pushes the matter so that he can get a profit therefrom, and thus the boys of our country are brought to ruin. Therefore the only way this accursed thing can be stopped is to start at the source. I am sending you "Government by Administration," which I wish you to read carefully as doing me a favor. Then I am daily asking God to give you the light and the needed grace to swing your department in *GLEANINGS* over as an "upheld banner" for prohibition, where it ought to have been long ago. And may God bless you through the remaining days of this life, and give you "an abundant entrance" into eternal life which comes to you and me through belief in his dear Son.

Borodino, N. Y., Sept. 2. G. M. DOOLITTLE.

Many thanks, old friend, for having given me still another glimpse of the iniquity of the liquor-traffic, especially regarding the licensing of it. I am certainly, heart and soul, and always have been, in favor of Statewide prohibition, and, in fact, for any thing that makes the saloon-keepers squeal and shake in their shoes. Inasmuch as there may be some readers of *GLEANINGS* who have never seen the Prohibition platform, I submit it below; and I submit, also, to every man, woman, and child who looks it over, if it is not the best and wisest platform before our country or before the world.

THE PROHIBITION PLATFORM.

The Prohibition party in national convention at Atlantic City, New Jersey, July 10, 1912, recognizing God as the source of all governmental authority, makes the following declarations of principles and policies:

1. The alcoholic drink traffic is wrong; is the most serious drain on the wealth and resources of the nation; is detrimental to the general welfare and destructive of the inalienable rights of life, liberty, and the pursuit of happiness. All laws taxing or licensing a traffic which produces crime, poverty, and political corruption, and spreads disease and death, should be repealed. To destroy such a traffic there must be elected to power a political party which will administer the government from the standpoint that the alcoholic-drink traffic is a crime and not a business, and we pledge that the manufacture, importation, exportation, transportation, and sale of alcoholic beverages shall be prohibited.

We favor:

2. Suffrage for women on the same terms as for men.

3. A uniform marriage and divorce law; the ex-

termination of polygamy, and the complete suppression of the traffic in girls.

4. Absolute protection of the rights of labor, without impairment of the rights of capital.

5. The settlement of all international disputes by arbitration.

6. The abolition of child labor in mines, workshops, and factories, with the rigid enforcement of the laws now flagrantly violated.

7. The election of United States Senators by direct vote of the people.

8. Presidential term of six years, and one term only.

9. Court review of postoffice and other departmental decisions and orders; the extension of the postal savings bank system and of rural delivery, and the establishment of an efficient parcels post.

10. The initiative, referendum, and recall.

11. As the tariff is a commercial question, it should be fixed on the scientific basis of accurate knowledge, secured by means of a permanent omnipartisan tariff commission with ample powers.

12. Equitable graduated income and inheritance taxes.

13. Conservation of our forest and mineral reserves, and the reclamation of waste lands. All mineral and timber lands and water powers now owned by the government should be held perpetually, and leased for revenue purposes.

14. Clearly defined laws for the regulation and control of corporations transacting an interstate business.

15. Efficiency and economy in governmental administration.

16. The protection of one day in seven as a day of rest.

To these fundamental principles the national Prohibition party renews its long allegiance, and on these issues invites the co-operation of all good citizens, to the end that the true object of government may be attained, equal and exact justice for all.

WHISKY AS A MEDICINE; DO OUR UP-TO-DATE PHYSICIANS RECOMMEND AND USE IT AS A RULE?

This matter was brought up by a full-page advertisement in the Boston *Globe* of Sept. 10. The full-page sheet was sent to me with the suggestion, "Here is a text for you." The big advertisement is from the James E. Pepper Distilling Co., of Chicago. In big letters we read, "37,814 high-standing physicians endorse this whisky in health or sickness." Toward a hundred brief letters from as many physicians scattered all over the nation are printed in this sheet. These doctors declare they have used(?) or tested the whisky in question, and pronounce it good, and that they also continue to use it in their practice. Now, we very strongly question the statement that these letters are from "high-standing physicians." They are mostly drinkingmen certainly, for they say so. Let us now look into the matter squarely. The railroad companies of our land have decided to have nothing to do with men who use intoxicants. Is it too much to ask that the *physicians* of our land, our family doctors, step up on to the same high plane of total abstinence in their habits, and, as far as possible, in their practice? Suppose the good people of our land should stand up and

declare that they will no longer employ a physician who is not a teetotaler.

But the above, to my mind, only indicates the *desperate* fight the brewers and distillers are making to hold their trade. It is not to be wondered that in the whole United States they have been able to find well toward 40,000 doctors who might accept a gift of some choice whisky, and give three or four lines of testimonial in return. Drowning men, you know, catch at straws.

This reminds me that, during the coming week, the brewers of the United States will hold a great conference in Cleveland, O.; and, saddest of all, the city mayor, Mr. Baker, has consented to give them an address of "welcome" to the chief city of Ohio. Shall we not follow the railroad companies again, and declare that we will never vote for a mayor who consents to give an address of welcome to a conference of brewers?

WOMEN SMOKERS OF CIGARETTES AT THE WHITE HOUSE, WASHINGTON.

It appears that a woman signing herself "Mrs. Wilson Woodrow" has been publicly defending women's rights to smoke cigarettes; and I do not know but I agree with her when she says that a woman has as good a right to smoke cigarettes as men, and I would add, just as good a right to *vote* as men have. Well, this woman's name, "Mrs. Wilson Woodrow," has been confusing the public, as well it might, with the name of Mrs. Woodrow Wilson, the wife of the presidential candidate; and because of this, Mrs. Wilson, for the first time in her life, has come out in a public statement. See the following, which we clip from the *Baltimore Sun* of August 13:

What Mrs. Wilson wished to have fully understood was that, if she becomes the first lady of the land, she will not, as has been said in a widely distributed interview, have packages of cigarettes in her personal desk at the White House, and smoke them with her callers.

Mrs. Wilson was represented as saying that she thought a woman has as much right to a cigarette as a man; that the existing prejudice against woman smoking is to the last silly and absurd; that smoking cigarettes is a question of manners, not morals; that it promotes good fellowship; that some women feel that a cigarette calms their nerves and helps their brains into working order, and that she enjoyed a cigarette as she enjoyed after-dinner coffee.

It seems from the above (in all a rather lengthy article) that the editor of the *Ohio State Journal* wrote Mrs. Wilson a letter, protesting emphatically, and below is her reply:

Dear Sir:—I have just received a copy of the *Journal* with your editorial entitled "Smoking Women," and I beg leave to deny indignantly the statement that I approve of women smoking cigarettes. The interview upon which your editorial

was based is a pure invention. I intensely dislike the cigarette-smoking habit for women; in fact, so strong is my feeling on the subject that my real danger lies in being unjust and unkind in my judgment of those who differ with me in this respect.

But certainly no woman in our household ever has or ever will smoke. Quite apart from the bad taste of it, I believe with you that it has an extremely injurious effect on the nerves.

ELLEN A. WILSON.
(Mrs. Woodrow Wilson.)

Governor Wilson has also given his indorsement of her letter.

Before dropping this matter let us consider for a minute what was implied in Mrs. Wilson's letter. If it were indeed true that women folks at the White House, or at least *some* of them, have been in the habit of keeping packages of cigarettes in plain sight at the White House, and smoking them with their callers, would it not be about time that we should expect the finger of the Almighty to write on the wall, "Thou art weighed in the balance and found wanting"?

Perhaps it is no more than proper to allude to what has been reported in one way and another. See the following:

TABACCO ABSTINENCE.

The columns of Our Homes department several times have boasted that Mr. Theodore Roosevelt does not use tobacco; but has the editor noticed how often our daily press contains items wherein it is related that Mrs. Alice Roosevelt Longworth, in an extremely brazen manner, parades to the public the fact that she smokes, and is particularly fond of the cigarette? One might answer this with the argument that the father should not suffer for the daughter's wrong, and under some circumstances he should not. I am, however, enclosing a short clipping, "The Campaign Cigarette," and can not refrain from adding that, from what I can learn of Mr. Roosevelt, he is the "boss," and I do not think that his lieutenants would issue such an article against his wishes.

Lake Roland, Md., July 26.

The clipping referred to above (also from the *Baltimore Sun*) states that Roosevelt's picture is on the packages of "campaign" cigarettes. The question is, does Ex-president Roosevelt know this? and does such a course have his sanction?

THE EARLY JOE APPLE IN NEW ZEALAND.

Regarding the Early Joe apple, Messrs. Thos. Horton, Ltd., nurserymen, of Hastings, N. Z., have the above name in their catalog. Their description is: "Fine little dessert apple; yellow, with red stripes; ripe January [say July with you]; tree a good cropper, and blight proof." Price 25 to 60 cts. each; \$2.50 to \$7.50 per doz., etc. I will try to find room for one sample, in view of its praise in *GLEANINGS*, July 1st, and other issues.

C. R. BELL.

Otaki Railway, New Zealand, Aug. 3.

GOOD READING-MATTER FOR THE HOME, ETC.

My husband and son, G. W. Hammond, who is a subscriber to *GLEANINGS*, are both in the bee business. Both are members of the Baptist Church and I wish to thank you very much for the pure reading-matter you are sending into my home every month, especially the issue of Aug. 15. We are for prohibition. May you prosper.

MRS. E. M. HAMMOND.

OCTOBER 15, 1912

NO. 20

Editorial

DURING this month a good many colonies will have to be united. Many have complained that bees go back to their old stand; but if the work is done rightly there will be no returning. Wait until the first four or five days of cool weather, then early in the morning do the uniting, removing the hives from the old stands entirely.

STINGLESS BEES (?) ETC.

THE clipping below seems to have been having the run of the daily papers. We clip it from the *Detroit News* of Oct. 1:

The stingless bee has at last arrived, having been produced by an English apiarist named Burrows after two years of experiment. A description of the new bee, which has been received here, says that the hybrids are splendid workers, and are less liable to disease than the ordinary honey-producer. Burrows mated Cyprian drones with Italian queens to produce the new bee, which, while possessing a stinger, can not use it as a weapon of offense.

Something like twenty years ago, when D. A. Jones brought the first Cyprian bees from Cyprus, the same or a similar claim was made, and there was just a grain of truth in it. The Cyprians, or a cross such as mentioned, seemed quite slow about getting on the "war-path;" but it soon transpired that, when once roused up, say by untimely meddling, they stung worse than any other bees we had. So much for newspaper canards.—A. I. R.

HONEY-MARKET CONDITIONS; CORNERING THE MARKET.

AT the present time there seems to be an effort on the part of some one to corral the crop of western honey. Small buyers are complaining that they are unable to supply their needs. While this will have the effect of boosting prices of both comb and extracted, the people who are doing the cornering should not make the mistake of holding on too long nor boosting the prices too high. Now is the time to sell honey—especially that in the comb. When cold weather comes on, the prospective buyer is confronted with the hazard of granulated comb honey. He will be shy about

placing his order, and the result will be that some one will be left with a lot of comb honey on his hands that he can't sell.

SHIPPING BEES IN 1, 2, AND 3 LB. PACKAGES WITHOUT COMB.

IT is usually very difficult to send bees without combs in extremely hot weather any distance. While we have had splendid success in making such shipments all over the country when the weather was suitable, we have had difficulty when it turned extremely warm, especially with the larger packages of bees. Lately we have been providing bottles of water; and in every case where the water was given, the bees went through in good order. In some cases not a single bee was reported dead, notwithstanding the weather was very warm when the bees were *en route*. Experience has shown that bees in high temperatures require water. Without the means of getting it they will die in a few hours. This explains why nuclei and colonies on combs will go through in good order, because the water in the honey would seem to carry them through. On the other hand, without combs, and only bee candy, under similar conditions, they will go through in bad order.

We took some little self-sealing tin cans and filled them with water, and, after screwing the cover down, made a single perforation through the cap about the size of a pin. These were secured in the center of the cages, when, presto! the bees would go through with the loss of scarcely one of their number.

PARCELS POST AT LAST AND ITS EFFECT ON BEE CULTURE.

OUR readers will remember how, during the past three or four years, we have been urging them to write to their Representatives and Senators in Congress, requesting their favorable consideration of the various parcels-post measures that have been submitted from time to time, and how as often they have been put to sleep in committee;

but during the past year the demand for parcels post has been so insistent, and the spirit of the age has been such, that Congress has finally yielded and given us parcels post on the zone system, the same to become effective next January. While it is to be admitted that the general plan proposed is somewhat experimental, yet a movement has been made which, we believe, will result in an effective parcels post.

Congress did not deem it practicable to give us the same kind of parcels post that has worked so satisfactorily in nearly all European countries—a system that allows one in Europe to send a package not exceeding 11 lbs. in weight any distance at a certain definite rate. On account of the immense distances in the United States, our lawmakers seemed to feel that any scheme of parcels post with no distance limit, which would be feasible in a small country, might bring a heavy postal deficit in the United States, and so the zone system as outlined by Dr. Miller on page 648 of this issue was adopted.

We notice that a number of the journals—notably the *Scientific American*, believe that the zone system of charge according to the distance the package is to go “will be the most vexatious and annoying feature of the new plan, and contrary to the general purpose of our postal usage—that is, one rate regardless of distance traveled.” We can not help sharing this feeling. Whether the express companies or other “interests” had any thing to do with opposing a scheme of one rate for all distances we do not know. We see no reason why the United States can not carry parcels-post packages to all parts of the United States at the same rate for all distances, if it can send letters, books, and other matter on the same basis. According to the law of average, the long and short distances would equalize at a point that would warrant a uniform rate, and thus avoid the complicated system of the multiplicity of rates we are to have. However, we are not inclined to criticise, but feel, on the other hand, that every loyal American should unite in giving the new plan a careful and thorough trial—especially as the Postmaster-General has authority to change the classification of mailable articles, weight limits, rates of postage, or the system of zones. If he is a broad-gauge and far-seeing man—one who can not be influenced by the “interests,” well and good. We will assume that he is, and that he will be just that kind of man; therefore we are optimistic concerning the future, and thankful—mightily thankful—that we have

secured as much as we have. Once the people get a chance to try out parcels post they will demand that it be retained.

The effect of parcels post, we believe, will be to reduce the expressage on bees and honey in small lots. Hitherto the rates have been almost prohibitive on packages weighing over 7 lbs.; but as the express companies have done in the past, so they will do in the future—meet rates of postage anywhere and every time. They will be compelled to do so and more. This would mean that we would be able to send bees in the form of pound packages, or nuclei and full colonies, at rates that will be much more equitable and within reason. It is very possible that we may be able to send bees by mail in pound packages; but we question the wisdom of making the attempt, for the reason that some fool (pardon the expression) might send out a package that would let bees loose in the mail car, or in some public place where they would do a great amount of damage. There is no telling what might happen. The Postmaster-General or any of his assistants who have unlimited powers to make rules and regulations might bar bees from the mails entirely.

A STUDY OF THE WORK OF A QUEEN.

OUR cover picture for this issue is from a photograph taken by Dr. E. F. Bigelow, Arcadia, Sound Beach, Ct. Dr. Bigelow's explanation of the work of the particular queen that laid these eggs appears on page 657, together with two other illustrations. Of course, it is understood that a photograph does not reveal the depth of the cell. In a real comb the cell is nearly half an inch deep, so that the eggs are not as easily seen as they are in this picture.

This cover picture in many ways presents an interesting study. It shows that the best of queens, even when there is plenty of room, may lay two eggs in one cell. Right in this connection, however, it may be well to point out that, when there is more than one egg in a cell, the queen may not be responsible. The trouble may be due to a lack of room, in which case the queen literally drops eggs promiscuously about the comb, very often not getting them into the cells at all. At such times the workers pick up these eggs, and it would not be at all strange if they placed them in the cells, for at certain times of the year it is not uncommon to find cells which contain even as many as ten or fifteen eggs. A beginner confronted by these conditions, and having heard something about laying workers, is apt to conclude

that his queen is "no good," or else that laying workers have developed. Unless the queen were actually found, there might be some grounds for supposing this condition to indicate laying workers, for it does not look at all unreasonable to suppose that laying workers may drop their eggs promiscuously, and that the bees themselves pick them up and place them in the cells. Of course, if laying workers have been at work very long, scattered drone brood in worker cells is likely to be the result.

Whenever a queen is crowded for room, it is not uncommon to find an egg and a larva in the same cell, or even two larvæ. If the experiment is tried of grafting two larvæ in a single queen-cell, the bees will feed both of them until it is time for the cell to be capped over, and then one of the larvæ disappears.

Notice that one of the cells shown in the cover picture contains a larva instead of an egg. This cell might have been the first one in which the queen laid, although it is more likely that this egg hatched a little in advance of the other. It is certainly true, as we have pointed out in these columns before, that larvæ from the same queen and of the same age vary greatly in size, and it would not be unreasonable to suppose that certain eggs hatch more quickly than others. Some hens' eggs hatch more quickly than others, and some chicks make a much faster growth; so it is not surprising that the same would be true in case of queens' eggs and larvæ.

But to return to our picture. We should explain that the top of this picture does not represent the top of the comb as it originally hung in the hive. Fig. 2, page 658, shows a small portion of the same comb in the correct position. While there is not absolute uniformity by any means, it is safe to say that a queen while she is laying an egg *usually* has her head toward the upper part of the comb, and that the egg is *generally* attached to one of the upper sides of the base of the cell near the center. If the comb is held vertically, the egg when it is first laid does not lie in a horizontal position, but inclines downward toward the center of the cell somewhat. The second day after the egg is laid, it inclines still more, and the third day it lies almost flat on the base of the cell. It is thus possible to calculate more or less accurately the time when the egg will hatch.

The color of the egg varies quite a little, from nearly pure white to a rich cream. The size also varies considerably when those of different queens are compared. In

fact, the color and size seem to vary fully as much as do the color and size of hens' eggs.

REPORT OF THE BEE INSPECTOR IN COLORADO FOR 1911.

THOSE who are inclined to throw cold water on honest efforts toward progress along the line of eliminating disease from our country, and who believe that bee inspectors "do more harm than good," etc., should read the 1911 report by Wesley Foster, the State Bee Inspector of Colorado. Mr. Foster opens his report by explaining that the appropriation of \$1000 for a year is so small an amount that it has been necessary to confine the work to the counties that can pay for a deputy county inspector to work under the supervision of the State Entomologist. The county inspectors who were doing inspection work under appointment from the county judges have been retained as deputy inspectors where the county commissioners were willing to pay their salaries and expenses. The prospects are favorable for a longer list of counties that are willing to help out in this work for 1912.

Five years ago fourteen per cent of all colonies inspected were affected with foul brood. In 1911 less than two per cent were found infected. Moreover, a carload shipment of bees from Kansas, where foul brood is prevalent, was kept from being shipped into the State.

The following table, condensed from the statistics in the report, shows briefly what has been done.

County.	Inspector.	Inspected.	Diseased.
Otero,	Wesley Foster,	605	1
Prowers,	" "	910	0
Montrose,	" "	813	79
Garfield,	" "	40	..
Delta,	" "	971	201
Boulder,	" "	140	2
Boulder,	W. C. Dyer,	435	1
Bent,	D. S. Jenkins,	22	0
Garfield,	O. V. Coulter,	343	47
Montrose,	Robert E. Foster,	3494	176
Fremont,	F. W. Brainard,	987	184
Adams,	Walter Martin	675	28
Prowers,	D. C. Polhemus,	385	0
Montrose,	J. R. Miller,	1334	176
Otero,	V. O. W. Hopper,	2437	138
Mesa,	William Harkleroad,	8075	130
Montezuma,	R. W. Calkins,	246	148

Some idea of the extent of beekeeping in Colorado is gained from the full report. Notice that in six counties there were more than a thousand colonies inspected, and in Mesa County alone over 8000 colonies were inspected at least twice, and some of them the third time. The inspector in this case, William Harkleroad, evidently did not have much spare time. In all, 26,861 colonies in the State were inspected, and 1576 colonies were found diseased.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

ELIAS FOX, I'm with you, p. 564. I believe I can more successfully combat the faults of a bad cellar than of a bad out-doors.

W. G. SAWYER faces his hives toward the cellar wall, p. 564. I've always faced 'em t'other way—thought it gave them warmer air. I wonder which is better.

G. M. DOOLITTLE, you say, p. 617, that opening cellar doors at night always seems worse than nothing when the air outside is warmer than that inside. Not in "this locality." But your head is level and your heart right on the liquor question, p. 643.

THE *Canadian Bee Journal* is crowing over the acquisition of F. W. L. Sladen, F.E.S., as assistant in apiculture to Dominion Department of Agriculture. I'd crow too. In fact, I feel like crowing that he is on this side the ocean. Those Canucks can't keep him all to themselves, you know. He's too big a man.

THIS YEAR is the record one for long-continued blooming of white clover. Beginning the last end of June it has bloomed continuously till now, Sept. 30, when a good deal is still to be seen in bloom. But I don't know when it stopped yielding. [Clover continued up until late here; nor do we know just when it ceased to yield.—Ed.]

THIS SEASON began in a hopeless style. I fed in June to prevent starving. Then about June 25 white clover began to bloom, and, except for wet days, there was no let-up in the flow from clover or something else until about Sept. 20. Four colonies have given respectively 191, 192, 198, and 198 sections. Not so bad for a season beginning June 25.

CHARGES for the new parcels post, effective Jan. 1, 1913, are a little confusing. I figure it this way: City delivery, or on a rural route, 1 ct. a pound, and 4 cts. extra on each package; within 50 miles in a bee-line, 3 cts. a pound and 2 cts. extra; within 150 miles, 4 cts. a pound and 2 cts. extra; 300 miles, 5 cts. a pound and 2 cts. extra; 600 miles, 6 cts. a pound and 2 cts. extra; 1200 miles, 7 cts. a pound and 2 cts. extra; 1400 miles, 9 cts. a pound and 1 ct. extra; 1800 miles or more, 12 cts. a pound. [See editorial columns.—Ed.]

A. I. ROOT, that alfalfa business, p. 569, looks revolutionary and almost like romance. Think of plants set 2 feet by 3 feet 8 inches apart! I've been out and measured and counted carefully an average

spot of my alfalfa, and there are 20 plants to the square foot. That means 147 plants for every one that ought to be. Then think of transplanting an acre (5940 plants) in a trifle less than an hour! What's that transplanter like, and what does it cost?

THE *Practical Farmer*, page 491, says, "Some States have proscribed sweet clover as a weed, and have imposed penalties upon those who allow it to grow." Can you tell what States? [Sweet clover is included among the noxious weeds in Ohio. We do not know about other States; but we infer from reports that have come in that two-thirds of the other States in the North, at least, have a similar law.—Ed.]

A CORRESPONDENT asks how to winter a weak colony in Tennessee. If very weak, say bees covering three combs, I would unite with another colony. Otherwise I would winter on summer stand, protected, if only by cornstalks—better a box—open in front and well protected on top. [Something will depend on the locality. In the colder climates, the cellar is the place to put weak colonies; but in a climate like that of Tennessee the doctor's advice is all right. Oftentimes, and perhaps in most cases, south of the Ohio River, single-walled hives that are protected by windbreaks will winter almost as well as hives with protection.—Ed.]

ELMER HUTCHINSON, *Review*, 328, thinks temperature a secondary matter in a *very dry* cellar, with good stores and plenty of good healthy bees. In one of his cellars thermometer varied little from 34 degrees from fore part of January till the last week of March, and in 30 years he had never had bees winter better nor consume less stores. I've had the same experience with 50 degrees or higher. No one thing in cellar is more important than air—air, pure air, lots of air. Good for bees, babies, and big bodies. [In all of our experience a temperature of 34 F. in a bee-cellar, if long continued, has generally been very disastrous to the bees before spring. As there is such a great variation in thermometers we arise to ask whether the thermometer that recorded 34 in the cellar under consideration had been tested. We never could succeed in doing good wintering in a temperature below 38, and even then it must not stay there very long. We can winter well with a temperature varying from 40 to 60, providing the ventilation is sufficient and the cellar

dry. We partly agree with Mr. Hutchinson in saying that the temperature is secondary to dryness and ventilation.—Ed.]

SIEGWART says, *Schweiz. Bztg.*, 202, that when bees are shipped without combs or other means to give them a good foothold, many a bee loses its life when the package is thrown, because of the bursting of the crowded honey-sac. If that is confirmed, it seems there might be some danger in the ordinary shaking of bees, especially if they fall upon a hard surface. [We suspect there is something in this. When we first began shipping bees in pound and half-pound packages we did not (as we now do) make use of a series of roughly sawn slats about $\frac{3}{4}$ inch apart, fastened longitudinally through the cage. The result was that many of these packages were reported dead. In later years we put in these supporting slats, and find the bees go through in much better order. The slats are put close enough together so that they act somewhat like combs in supporting the bees. In the old pound packages there was a large amount of vacant space, making it necessary for the bees to hang on to each other. This, we thought, cost considerable leg strain or weariness, and would, therefore, to a certain extent, reduce the vitality of the bees.—Ed.]

PENN G. SNYDER, replying to your question, p. 601, I think the Swiss introduce their virgins to the mating nuclei the same as the Root Co. introduce queens, at least sometimes, to bees in one of their new shipping packages by means of a candied cage. Your experience on three different occasions differs from mine on hundreds of occasions. When a dequeened colony has brood in all stages, it is a rare thing for a virgin to emerge from its cell in less than 12 days, but quite often it is more than 12 days. If it emerges in 12 days, then the larva chosen must have been not more than a day or two old. You say, "Naturally, the older the larvæ selected, the earlier the queen emerges from her cell." That's a rather common idea, but fallacious. We are told that, after a worker larva is fed three days, it is weaned. Then it is fed two days more, and the feeding of that two days makes it five or six days more in developing. If it should be chosen for a queen just before being sealed up, do you think it would then develop within 15 or 16 days of the time the egg was laid? And if chosen any time after being weaned, do you think there would not be a postponement of the time of emergence? If chosen when four days old, if such a larva could be made into a queen at all, it seems fair to guess it would take it so much longer

to develop that the younger larvæ would beat it getting out of its cell. But I don't believe my bees ever chose a four-day-old larva for a queen, if they had any thing younger.

NOT OFTEN is my enthusiasm stirred as it was by a sight of a 3-lb. package of bees without brood or bees, received by express from the A. I. Root Co. They've got the thing down fine as to the matter of package. A cubical cage of wire cloth has inside supports for the bees; and the bees looked so bright and contented—only four dead at the bottom—that I spent some time admiring the outfit as a real thing of beauty. It would be impossible to ask a more successful shipment, unless those four bees could be saved, and it is possible they died of old age. What better way of getting a valuable queen than in such a package? Just run the bees into a hive with perhaps a frame or two of brood, and there you are—no introduction, no risk. [We may explain to our readers by saying that we are making experiments in testing packages suitable for shipping bees, without combs or brood, thus eliminating the danger of transmitting foul brood of any sort, and at the same time very materially reduce the weight, and consequently freight or express charges. Combs and the hive constitute over 75 per cent of the weight of a medium colony of bees; in other words, an ordinary colony with 3 lbs. of bees and brood with honey would run about 45 lbs. shipping weight. Three pounds of bees without the brood, combs, or hives comes within 6 lbs. Bees go at the rate of a rate and a half by express. While a 3-lb. package of bees is not the equivalent of a medium colony, 5 lbs. would be. A 5-lb. package would run about 9-lbs., gross weight, as against 45 lbs. for the equivalent of a colony of bees in a ten-frame single-walled hive. If the reader will turn back to our editorial on page 502, August 15, on migratory bee-keeping he will understand a little better what we are driving at in these experiments; in other words, we hope to eliminate the possibility of transmitting disease, and 80 per cent of the weight in shipping colonies of bees in single lots or in carlots. This would make it possible to ship 1000 colonies of bees in one car as against 300 on combs in hives. The possibilities are so great, and would mean so much to the industry, that we feel inclined to do a little experimenting in a small way, with the view of going at it in a larger way if the preliminary experiment seems to justify it.—Ed.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

Recently I found a young queen laying nothing but drone eggs; but later she laid worker eggs all right. Whether she laid the drone eggs before she had mated or because of her inexperience I have not been able to determine.

* * *

That experiment of coloring bees and letting them fly gives us some useful information as related by Dr. Miller on page 356, July 1. It accounts for the spread of disease, as doubtless young bees go to strange colonies more frequently than older bees; and these young bees may have their stomachs filled with larval food containing more or less disease germs. I believe it a good thing where there is danger of disease; or, where it exists, to set hives some distance apart.

* * *

Mr. Byer somewhere speaks of blueweed as a source of honey. This appears to be the same as that known in Virginia as blue thistle. It has become quite common in some parts of Eastern New York and Western Vermont. One beekeeper in the first county south of me said he had 500 or 600 acres of it within range of his bees. It is considered a very good honey plant, but regarded by the farmers as an unmitigated nuisance. We have found it in three places this season in this county—the first I have ever known here. Beekeepers have a right to raise what they will upon their own land providing they do not let anything spread to their neighbors that will injure them. Honey produced by such means will in the end be bitter honey. An approving conscience is more to be desired than the finest honey in the whitest combs.

* * *

Mr. Walter S. Pouder is a brave man to write as he does on page 379 of the modern claptrap outfit for the ordinary plain farmer beekeeper. And he sells supplies too! The facts are, or appear to be, that only about one beekeeper in ten who attempts keeping bees in improved hives is fit to do so. An improved movable-comb hive is all right in the hands of an improved intelligent beekeeper; but as the average farmer keeps bees I believe the old box hive is far preferable for him and everybody else unless his neighbors are anxious he should go out of business, as he is fast doing. A "bee inspector" has a chance to see all sides and kinds of beekeeping; and of all the absurd things is an im-

proved hive in the hands of the careless farmer who does not look into a hive three times a year, or even once. It is difficult to get into most of such hives, even with a hammer and chisel. I can not express my disgust. There should be, as Mr. Pouder suggests, two kinds of outfits for beekeepers—one kind with every desirable device for scientific beekeepers; and another kind, made in the simplest way, for those to use who will not do any thing but put bees into them and put on and take off supers—a sort of "letalone" hive, as my friend Latham calls his.

* * *

Dr. Phillips' statements on page 451, July 15, in regard to the success of the Colorado Honey-producers' Association, set one to wondering if the same methods could not be used to profit in other States. I have given the subject some thought at one time or another, but have so far been unable to see how such an organization could be made to work here in New England. Colorado beekeepers have a distant market, while we have one near at hand. Their honey must or should be shipped in carload lots to save freight. Here not infrequently the buyers come from the city and look over the different lots of honey produced by different beekeepers, and the grading is arranged between them. Then, again, each beekeeper has his name on his goods, and they are bought by the city dealer on its reputation, or, as is often the case, is sent to the city to be sold on commission. Take our own crop as an illustration. We found time in July to pack over 150 cases ready for shipping at a moment's notice. By August 2 every case was gone. Orders came in for from two to twenty-five cases, and it went to half a dozen or more places, and more will be wanted as soon as we can get it ready. Now, suppose we had a honey-producers' association. We would have had to wait until others had honey enough for a carload, which might be September. Then the honey would have to be sent to some central station to be inspected and graded, and finally shipped to some central distributing city where it would be broken up into small lots and shipped again to jobbers, and perhaps again to retail dealers. We ship directly to jobbers and retail dealers, and I can not help thinking our way is better for us, and I have no doubt the Colorado method of marketing their honey is better for them.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

The following letter is self-explanatory, and speaks highly for our State Association:

Mr. Chadwick:—I notice your statement, page 578, Sept. 15, in regard to my bees eating T. Kataoka's strawberries. Mr. Kataoka dropped his suit for damages Sept. 6. Officers and members of the California State Association gave me their help in every way possible, and no doubt the berry-grower saw he had no chance to win.
Pasadena, Cal., Sept. 25. GEORGE B. LARINAN.

* * *

DESIRABILITY OF RANGES.

I had always supposed that there were no ranges equal to those of the button sage, so far as wild growth is concerned, and to a great extent I still believe this to be true; but that there are localities that yield heavily where button sage does not bloom is also true, many of the latter having a great advantage in early honey and pollen that stimulate breeding when there is a shortage of such flora, as was the case in many purely sage ranges this season.

That some plants will yield a surplus in certain localities, while in others the same plants have never been known to do so, also seems quite certain. But it can be seen that, while general conditions can, in a measure, be forecasted, local districts may secure surplus in spite of general *off* conditions, and the season would, of necessity, have to be very bad indeed if some honey from wild flora were not secured.

* * *

I have returned from my ten-day trip among the beekeepers of Southern California. To say that I enjoyed the journey would be putting it mildly, though it was not by any means a continual round of pleasure, and it ended much short of the territory I had planned to cover—due, largely, to the fact that I found many more beekeepers than I had thought there were, all of whom gave me such a cordial reception that oftentimes it afforded more pleasure to tarry than to travel on.

To give in this department the details of my trip would be impossible, so I will give only a summary of certain conditions that struck me most forcibly.

First, I am more nearly convinced than ever that there is a condition expressed by two words that have more to do with our honey-flows than any other one thing; and that is, *late moisture*.

Second, that there are conditions that

surround some of our heaviest-yielding localities that make them less desirable than some that do not have such an abundance of flora, or that yield as light a grade of honey.

Third, that beekeepers are a demoralized set so far as being organized or alive to their own interests. Nearly 75 per cent do not take a bee-journal, and can not be induced to do so. Some, when asked if they belonged to the State Beekeepers' Association, asserted that they had never heard of such an organization.

Let me now return to the first of the three given subjects, that of moisture. This does not mean rainfall entirely, though that is the chief factor in every case, directly or indirectly, and is also the first essential. The nature of soil and its adaptability to holding moisture is a great factor. Rain belts and dry belts in many localities are quite distinctly marked from year to year, apparently because of air currents passing through, to, and from the mountain passes. In other words, a greater amount of rain falls in certain zones of influence than in others. Freak rains, if this term is permissible, have a part in the production in certain localities. For instance, in the neighborhood of Sage, Riverside Co., there was a fall of four inches in May, and the beekeepers in that section are being favored by a bountiful crop of late honey. In another district, near Temecula, a thunderstorm caused a heavy fall in July, which swelled the crop in that locality wonderfully, while down along the moist lands of the Santa Ana River bed, sweet clover is said to be yielding noticeably.

Another case, much nearer home, is at Perris, Cal., where there was an exceptionally heavy thunderstorm early in the summer, and more than half an inch late in August. In that locality bees were drawing comb, storing honey, and breeding nicely.

The altitude is also a factor that must be considered. Naturally the higher altitudes get the heaviest rainfall, are the coolest during the summer, and retain their moisture longer than down in the blistering valleys. Regarding late moisture, as set forth above, I have dwelt on local conditions rather than general, yet the advantage of late general spring rains, following a sufficient winter fall to start the growth of honey-plants, is the greatest factor of all in producing bumper crops, such as we had in 1905.

Beekkeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

COMB OR EXTRACTED HONEY?

This question has often arisen, and has been discussed at length. It was not long ago when the arguments were in favor of extracted-honey production. The tide is drifting the other way, for we find that there is now a better demand and price for comb honey, and consequently its production should follow. We remember well when these discussions were in full sway, and we decided to drift more and more to the comb-honey side, for the very reason that there would be a better demand for this product if everybody else produced extracted honey. The result is that we are to-day advertising our business as exclusive comb-honey producers and shippers, and we have found that it has paid us to stand by comb honey. The demand for that kind has increased from year to year, in spite of the efforts on the part of the extracted-honey producers to advertise the cheapness and better value of extracted honey for the consumer.

We find to-day that the demand for comb honey is brisk here in the South, and at a good price, while extracted is begging for a market at the present time, and that at a lower price, in comparison to the comb honey, than ever before in our experience. While it may be cheaper to produce extracted honey, we have found that it is much easier to sell comb honey.

Of course, we are referring to bulk comb honey, a product that fills the bill for the masses as well as the richer class who want full value for their money.

* * *

COTTON HONEY VALUABLE.

We have found cotton honey to be a valuable product in Central and North Texas territories, and the apiarist who has his bees located within range of extensive cotton areas can count on at least an average crop, year after year, with more certainty than many of the other numerous honey-yielders that we have.

It is but a few years, comparatively, since cotton came into prominence as a honey-yielding plant. Years ago cotton honey was hardly known, this being due, perhaps, to the fact that the honey which the bees obtained from the cotton was attributed to some other source. But of late years, especially when it is grown on rich land, in valleys and river bottoms where the growth is luxuriant, cotton has come

to be known as one of the very best honey-yielding plants. It yields best when the atmosphere is warm and damp. On poor soil or on sandy land it does not yield nectar plentifully, and, in some cases, not at all. In the average season a good yield may be expected from cotton in the black-land districts and in the river valleys. Under favorable conditions it is not excelled by any other nectar-yielding plant in the cotton belt.

The yield is most abundant in the early morning, and it decreases toward the middle of the day as the atmosphere becomes drier. In the afternoon, unless the season is very dry and hot, the yield begins to increase again. During cloudy days, or when the atmosphere is damp, the yield continues abundantly throughout the entire day.

The nectaries from which nectar is secreted are located under the bracts next to the stem of the blossom. There are other nectaries located on the under side of the leaves, one on each of the three main ribs of the leaf. They can easily be located as small low indentations on both blossoms and leaves. There are three under each blossom, and those located on the ribs of the leaves are located about a third of the length from the main stem of the leaf. At the proper maturity of both buds or blossoms and young leaves, the nectar may be easily seen in a large drop in each nectary, and is easily gathered by the bees. During favorable conditions it is not necessary for the buds or "squares," as these are called, on the cotton plant, to develop into full bloom, but nectar secretion begins before the blossoms open.

Cotton honey is very light in color and mild in flavor when thoroughly ripened, and it compares favorably with the very best grades of honey. Honey from upland cotton, or that which is grown on poorer soil, has a slight amber color. When first gathered, cotton honey has a flavor which is very characteristic of the sap of the cotton plant itself; but this disappears as the honey ripens. During a heavy flow there is a strong odor in the apiary like that produced by bruising cotton leaves.

Ordinarily, cotton honey granulates easily, and in the granulated form is almost pure white and very fine-grained.

The flow begins ordinarily about July 1 and continues until frost, except when the fall of the year is a very dry one that causes the cotton to stop growing.

Conversations with Doolittle

At Borodino, New York.

BEE-CELLARS—CONTINUED.

"I have done some thinking about beecellars since I was here before, and have come to the conclusion that it will pay me to build a special cellar."

"What is the lay of the land near your apiary?"

"On the west of it, and facing the east, is a rather abrupt hill, rising about twelve feet high. The base of this hill comes near the center of the beeyard on the west. Will that be a good place for the cellar?"

"Most admirable; for where a cellar can be placed in a side hill, having a slope more or less abrupt, and the slope being on the side where the entrance is desired, the question of ease of access is settled, so that the labor of carrying in and setting out will be much less fatiguing than where from three to eight steps for a stairway have to be used. Then where the entrance can be on the east side, it is much easier to guard against the cold, and at the same time it guards fully as much against the heat of the sun in February, March, and April. The entrance provides also against the extreme high winds of the west which rage to a great extent above all others in this section. By the removal of very little earth you can have an entrance on a level with the bottom of your cellar, so that with a wheelbarrow or a hive cart the bees can be run right into the cellar, thus saving a lot of hard lugging and lifting."

"The soil of this hill is a sort of gravel. Will this be as good as any?"

"Many prefer sandy or gravelly soil, as there is less danger of dampness. But to my mind it makes very little difference. At the farmer's cellar, where my out-apiary is situated, water runs right through it in slight depressions cut for this purpose in a stiff clay soil, at all times when the ground is at all wet from fall rains; but so far as I can see, the bees winter there as well as anywhere. If the stores are good, bees seem to winter well in almost any cellar where an even temperature at some point between 38 and 45 degrees can be maintained. But with a cellar where the temperature is unstable, going anywhere from below the freezing-point up to sixty one week, and back again the next, or where it changes with every change outside, poor wintering is apt to result, no matter what the soil is."

"What about proper protection?"

"Having your excavation made to the

amount of about two square feet for each colony you expect to winter, say 8x25 square feet for 100 colonies as the floor surface, you will build permanent walls all around the sides about 7 feet high, but the top of the wall should not come more than six inches above the surface of the ground, or just enough to turn off all surface water at any time the soil might become excessively saturated with water. On top of these walls should be placed old or worn railroad rails, cut to the proper length if you can possibly get them, and on these put flagstones; or a covering of concrete can be made of suitable thickness to hold the earth which is to be placed on top, to a depth of at least three feet. Four feet would be better still. Over this earth is to be built a cover of some kind which will shed water. After the first year this covering of earth will remain dry, as the heat of summer will make all this as dry as dust. With four feet of earth over such a special cellar in a side hill, the temperature will not vary more than five degrees during the whole winter. Often during the whole winter, after the bees get settled down from being carried in, there is not two degrees variation in my cellar built on this plan, the mercury standing from 42 to 44 degrees during the five months while the bees are in this cellar. The doorway into the cellar should have 'wing' walls, turned at right angles for three doors, which should be two feet apart, thus enclosing two dead-air spaces of two feet each when the doors are shut. This is very essential to the maintaining of perfect protection and an even temperature."

"What about ventilation?"

"This is a matter I am not wholly certain about. I have wintered bees with abundant ventilation provided through what is known as sub-earth ventilators, which take the air from 100 to 200 feet away from the cellar, and carry it under ground at a depth of two or more feet, so that it becomes the same temperature as the cellar by the time it enters it. I have also wintered bees without any provision being made for air, keeping the cellar as close as possible, and secured fully as good results as I did when I had the ventilation."

[We know that Mr. Doolittle has had good success with his cellar; but nearly every other beekeeper has secured far better results with abundant ventilation.—ED.]

General Correspondence

THE SECRET OF THE FLOWERS

BY P. F. X. RYAN

The glorious diadems which are studded so bountifully over Nature's beautiful vesture have always possessed a peculiar charm for me; and greatly, therefore, did I welcome Mr. J. H. Lovell's learned effort to penetrate the hidden meaning of these mysterious gems of Nature, and to ascribe to them some significance, real, not fanciful, as is the case with the conventional "language" so dear to lovers. My object in writing is to offer a friendly criticism of a few points on which "I have my doubts," and I am confident that Mr. Lovell will rejoice to find some one ready to use the pruning-knife of friendly criticism on his work, and, if need be, to write further to elucidate such matters as may be doubtful or otherwise called in question. It is far from my intention to brandish the battle-ax of censure; and if I appear to do so, I pray he will forgive.

Referring to page 21, Jan. 1, it seems to me Gray was well within the mark in his assertion that

Full many a flower is born to blush unseen,
And waste its sweetness on the desert air;
for, as far as we can judge, in many instances all their glory is bootless, for there are "full many" which are self-pollinating, and even inaccessible to insects. They can not, therefore, take cover under the cloak of usefulness to insects as a *raison d'être* for their beauty and sweetness. They are, then, so to speak, "wasted on the desert air," though, of course, they proclaim the glory of the king who, clad himself in golden raiment, transmits a shimmering luster to Nature's habiliments.

However much Sprengel's opinion (page 22), that the bright hues of flowers serve as signboards to nectar-loving insects, may have gained ground, I must confess that I am personally somewhat skeptical; for I find the theory (and it is at most only a theory) confronted by many ugly facts. Nothing is more unscientific, and to me nothing is more distasteful, than to see scientific men making hasty generalizations, or parading scientific hypotheses in the garb of facts. Lubbock makes an assertion similar to Sprengel's, that the very arrangement of the colors, the circular bands and radiating lines, are all with reference to the visits of insects. Why, then, I ask, is the apple-blossom painted on the *back* and not on the front? Here, surely, is an instance of the complete un-

satisfactoriness of their contention, for the color of the *outside* is just about as useful an indication to the insects of the location of the nectar as a book's cover is to the scientist in quest of an article on paleontology in a work on evolution.

Let us take the case of wild flowers. Mr. Grant Allen, whose views in many ways seem to coincide with those of Mr. Lovell, points out that the *irregular* flowers are *variegated*, while *regular* forms have almost always a marked *uniformity*. If the insects were in need of a clue to aid them in their search for nectar, surely this clue would be more needful in regular form. But, as I have said, the variegations are in the irregular forms.

In pinks the color-bands run *transversely* to the course of honey-seekers, so that, if these finger-posts are trusted to, they play the poor little insects false, which is not in accordance with the habitual workings of kind Nature.

In the milkwort (*Polygala*) the sepals are the conspicuous part, and their veins are as clearly defined as many other petals; but the color indication leads just to where the honey is not; so it is evident that the weary insect in quest of nectar would be as badly fooled, if he trusted in these unreliable advertisements, as the weary traveler who, on seeing in the advertisements of a well-known hostelry every indication of the "home when from home" which he desires, and repairs thereto, only to find a magnificent *bar*. For bed and board he must apply elsewhere. I tried to enter on a study of the problem which Mr. Lovell treats so exhaustively, with a mind free from bias, and now make the candid admission that I have concluded my investigations by entertaining a learned doubt on the matter, pending the framing of a hypothesis which will give a more intelligent explanation of observed facts.

Having thus controverted Sprengel's major proposition, that the lines, dots, etc., serve as finger-posts in all cases, I reject his inference that the general color of the corolla advertises to insects, even when afar off, the presence of the desired nectar. I have known many instances of insects visiting flowers which secrete no honey at all. Are they the victims of a kind of confidence trick? If the color does all that is claimed for it, why have they not become acquainted with the meaning of the label, and why do they not refrain from wasting time in long tours of inspection which in every case prove to be fruitless?

Even Lubbock suggests that the object of their visits is a vain search for honey. The school of which Mr. Lovell seems to be a mild disciple insists that flowers require insects to assist in their propagation, and therefore must attract insects; and those which are the most attractive succeed best in the struggle which is so essential a part of Darwin's theories. But we have the order of cryptogams—ferns, etc., which owe not one tittle to the insect world. Sprengel says, "It seems that Nature is unwilling that any flower should be fertilized by its own pollen," and Mr. Lovell mentions that Darwin discovered that frequent crosses increase the vigor and productiveness of the stock, and that an occasional cross is indispensable.

But, on the other hand, Sir John Lubbock admits that the majority of flowers have retained the power of self-fertilization; and not only, indeed, have they retained the power, but their vigor and vitality are hardly rivaled by any crossbreds. The "lady's smock" (*Cardamine pratensis*) is prolific to a remarkable degree, and its flowers are incapable of fertilization. The Herefordshire "red streak" has existed now for close on to three centuries in spite of the fact that it is self-propagating; and there is not the faintest hope of its being rapidly exterminated, let alone dying out. The lesser celandine (*Ranunculus ficaria*) indulges in a wealth of blossoms, and appears in early spring when very few insects are astir. It contains not a single ripened head, and yet it multiplies prolifically. These instances surely upset Darwin's "Nature abhors perpetual self-fertilization." For a cross we require two *plants*; but in the case just cited we have not even two distinct *organs*. Those flowers which are propagated by buds and slips evince no disposition to realize Darwin's dream of their extinction; and, in spite of Nature's alleged abhorrence, they hold the fort.

On page 54, Jan. 15, Mr. Lovell says that "*occasionally* irregular flowers revert to ancestral stages and produce regular forms." "*Occasionally*," Mr. Lovell? What of the law discovered by Mendel? Some forty years ago George Mendel made his classical experiments with the common garden pea, in the case of which he abundantly proved a return to the parental forms. He experimented with seven pairs of characters which he crossed and left to self-fertilize. In the case of the crossing of the tall and dwarf pea he found that the first generation exhibited the characters of one parent only—that is to say,

all were tall. But the tall form, although for the time being subduing the dwarf, did not destroy its vital principle, which remained potentially in the tall form. In the second generation the dwarf parentage asserted itself, and 75 per cent displayed the dominant features (those of the tall), and 25 per cent those of the dwarf. The 25 per cent bred *true* to their dwarf ancestral type constantly and invariably. The 75 per cent bred 25 per cent true to their tall parent, the remaining 50 per cent being impure dominants. With these 50 per cent the history of their ancestors repeats itself. Here, then, the irregular form *unmistakably* "reverted to ancestral stages and produced regular forms."

On page 53 "beautiful flowers," and on page 239, April 15, "highly colored flowers," are designed for insects, and exist only where they can behold them. Where is there a more highly colored flower than the poppy? and yet it contributes not one iota of nectar to its insect visitors. If a casual connection between the gaudy-colored flowers and the insect world is to be established, or if they can in any way be said to be correlated, it seems that the flowers which have not the wealth of color, and which, consequently, have not been designed for insects, should not have any claim to their patronage; yet the common mignonette, the least likely to appeal to one's esthetic taste, and in which Nature has certainly not been prodigal of her paint, is most popular in the bee world. So also clover—perhaps the greatest honey-plant on earth. Still further is this statement of Mr. Lovell's controverted by the unobtrusive sycamore and lime (basswood) trees. On page 313, May 15, Mr. Lovell lets slip the statement that white flowers probably exceed all others in importance to beekeepers, which seems a little inconsistent in the face of his opinion on highly colored flowers just referred to, and in view of his reference to blue flowers on page 239 and 241, April 15. Blue flowers are not pre-eminently honey-bearing. In a vast acreage of blue hyacinths we do not see as many bees as in the inconspicuous and unpretentious green tassels of the sycamore. Heather and mignonette compare more than favorably with the speedwells and harebells, and even with the sage.

Here, too, is a very peculiar fact: The violet is blue alike in summer and spring. Why, then, is the spring violet popular with insects when the summer ones are denied the courtesy of their visits? Why, further—and this is a serious difficulty to

the Darwinian school—do not the spring violets, with their galaxy of insect friends, produce more seed than their summer sisters?

On page 53, Jan. 15, Mr. Lovell gives the prismatic colors as six. Does he not omit a seventh—indigo?

A word now about Haeckel, page 237, April 15. Ernst Haeckel is described by Mr. Lovell as "one of the most eminent of living biologists." This, I feel, is an overgenerous assessment of the scientific worth of the Jena biologist. First and foremost, Haeckel as an atheist bases his scientific investigations on a false foundation, and his views, consequently, can be taken only *cum grano salis* by Christians. A man who speaks of the fortuitous concourse of atoms, who does not postulate an internal law and a master hand to direct the destinies of all created matter, but, on the contrary, assumes the existence of random variation in this world of order, is not only a strange anomaly, but, in my opinion, sacrifices all his right to the name of a true scientist. The leading scientists of to-day reject Haeckel. In his lectures on the "Problem of Man," 1908, he dragged his scientific honor in the mire of falsehood, and, clothed in this robe of scorn, he can be regarded in no other light than that of a common forger. Haeckel's boldness made Darwin tremble; but Haeckel's boldness led an eminent scientist, Doctor Brass, to probe his allegedly scientific discoveries, with the result that he openly accused him of forging certain plates, and, moreover, drew from him the admission *that eight per cent of his drawings were falsified*. Here, then, is the evolutionist at large, claiming to be a scientist, and obtaining the much sought missing link by overt forgery!

And now let me conclude with a word with friend Crane, whose Siftings are a never ending source of pleasure and information to me. With him I cordially appreciate Mr. Lovell's erudite articles, page 153, March 15; but he introduces a doctrinal point on which I must beg to differ. It seems rather out of the way to speak of the Man-God as learning any thing from the hills and valleys, flowers, etc. If I mistake not, he was invested with all human science, and had naught to learn from his own creatures. And did he *command* us to consider the lilies? His words were, of course, addressed to the people about him, and even then could hardly have referred to constant meditation on these things, since he was only illustrating the providence of God. If he cared for

the lilies *a fortiori*, man's wants would not be neglected. In any case, it is no more binding to-day than the laws relative to ablutions, purifications, and circumcision of the old dispensation; and who, on reflection, will say it is "as much a command" as to say, for instance, "Thou shalt not steal"? Friend Crane also seems to understand the lily of our modern flowers; but it is really the anemone. In the Scriptural allusions the lily grew in the valley among thorns, in rivers, and in places where the shepherds led their flocks—in fact, almost everywhere, since the multiplication of the Jews is likened to it. On the occasion in question, Christ evidently pointed to some of them; and they must have been numerous or he would not have used the illustration. If the white lily is understood, Holy Scripture can not be explained, since it is known only a little in the north of Palestine, and even there it requires to be cultivated. It does not grow among rivers, etc., nor can the lips (as in the Canticles) be compared to it. The anemone, on the other hand, answers all the descriptions, and is appropriate to all texts.

Napier, Hawkes Bay, N. Z., July 14.

Bee Thoughts

The sun is up, the clouds are gray,
And promise now a pleasant day;
The earth is fresh and fair and bright,
And clover-fields are red and white.
The birds are on the wing, and we
Will go into the fields and see
If nectar in the flowers is found—
Enjoy the beauty all around.
What pleasure rare, what pure delight,
To wing the air this morning bright!
To leave the crowded hive, and fly
Above the earth, beneath the sky!
Now over pastures, flocks, and herds,
And meadows full of singing birds,
Past worthless flowers and rocks and rills,
By waving grain and wood-clad hills,
To scent the fragrant clover-fields,
And sip the sweet each foret yield,
Or rest beneath the shade, and sup
From many a linden's nectar-cup.
Nor yet forget, the while we roam,
To gather bread for babes at home.
Thrice blessed home! O mother! queen!
No bee like you was ever seen.
When we return, and flight is o'er,
Two pollen loaves, with nectar store,
We bring back to our home, and give,
And know the joy it is to live.
Our lives are brief, our days are few;
We pass away like morning dew;
And so we work with all our might—
Make play of work, for that is right.
And thus, by turning work to play,
We make the most of life each day.
Oh what a charming world is this,
When work is play and sweetest bliss!

J. E. CRANE.

GOT INTO BUSINESS AT ONCE

BY EDWARD F. BIGELOW

The ways of honeybees, especially their relations to the queen, are often surprising. Sometimes there is great difficulty in introducing a queen by any method; but once in a while it seems as if the bees were

extraordinarily desirous of a queen, and remarkably expeditious in liberating her. I recently had three queens come in by mail. Two of these caused a great amount of trouble and prolonged fussing and experimenting; but one was received more quickly, and began to lay eggs sooner, than any others with which I have ever

FIG. 1.—Piece of comb which the bees built down from an introducing-cage. Notice that the new queen immediately laid in nearly every cell.

FIG. 2.—Close view of eggs. Notice the cell in the lower left-hand corner contains two eggs, while that at the right-hand corner has a larva.

experimented. I opened the hive about ten hours after the cage was put in, and discovered that the bees had nearly eaten out the cardboard and candy in order to release her. I thought that, as every thing was progressing so well, I would leave the arrangements undisturbed for two days more. Imagine my surprise upon opening the hive to find a large piece of honeycomb hanging to the queen-cage, with almost every cell containing an egg. The queen had completed her task on this newly constructed comb, and had made good headway on a comb foundation of the regular size that the bees had drawn out. Such diligence is a joy, and that queen and her adopted daughters are the pride of this apiary.

Arcadia, Sound Beach, Ct.

[The two engravings and the cover for this issue show the eggs that this queen laid so quickly. In Fig. 2 a larva is shown in the upper left-hand corner. This photograph was probably taken at least three days after the eggs were laid, else there would not have been time for this particular egg to hatch. See editorial.—Ed.]

BETLES THAT MADE THE BEES CROSS

BY J. M. FRANCIS

We amateurs are constantly meeting with wonderful experiences which are quite familiar to the older beekeepers. Neverthe-

less, as I am looking for information I beg to say that, though I have been associated with bees more or less since I was a barefoot boy, and have commenced within the last year and a half beekeeping in a modest way, I am up against a proposition at the present time which has puzzled me not a little. I have three stands of Italian bees which, up to within the last thirty days, have been exceedingly gentle and tractable. I have never hesitated to pull the hives all to pieces, under proper weather conditions, without using any protection for the hands or face, and sometimes I do not find it necessary to resort to smoking. Imagine my surprise during the past three or four weeks to find my bees so ill-natured that one can hardly approach within twenty feet of them without meeting a hostile reception. I was much puzzled by this until I noticed that there were two or three balls of angry bees in the front of each hive, and on further investigation found that the center of these balls was composed of a beetle.

Our entomologist has informed me that this is the insect ordinarily known as the "bumble-flower beetle," or "June beetle" (*Euphonia Inda*), which is quite common in all of the Northern States. It usually feeds on the pollen of flowers, and, later in the season, upon ripened fruit. Undoubtedly the odor of the honey attracts these beetles, and they attempt to force their way into the hives. It then becomes

a struggle which lasts day and night. The bees cover the beetle, but find it impossible to sting it to death because it is covered with a horny sheath. They finally succeed in dragging it out a few inches, and then the beetle deliberately begins to force its way back to the entrance of the hive. They have been such a pest in my yard that I have killed 16 on one hive in a single week. You can imagine that this continual fight against the beetle has spoiled the tempers of the bees, so that they cease to draw any distinction between the beetle with the hard skin and the man with the soft one.

BACK-LOT PROFIT.

Before closing I beg to say that the year 1912 has certainly proved to my satisfaction that bees can be kept with profit in a city backyard. In April, 1911, I purchased a three-frame nucleus and tested queen which built up into a magnificent colony during the season. Honey was so scarce that I found it necessary to feed about 20 pounds of sugar in the late fall, but this was money well spent, as the hive came out of the cellar in April, 1912, with a tremendous colony well supplied with stores. In the early part of May this original colony swarmed, and from these two colonies I have already taken off over 150 lbs. of beautiful white-clover honey, nearly half of it in sections. Aside from this, both hives are running over with bees, and every particle of available space is

filled with white-clover honey, which is sealed for the winter. There is practically no pasturage nearer than a mile and a half, and it is very likely that a great deal of this honey was gathered as far as three miles away.

For the benefit of any office man who may see this, I would say that I should keep one or two colonies of bees for the mere pleasure of observing them, even if they did not yield a pound of honey in excess of their own requirements. To one who has the slightest taste for such things it is a great relaxation and pleasure to leave the office, to forget business worries, and study nature at first hand. Such little incidents as beetles and an excess of queens at the time of supersedure merely add interest and pleasurable excitement.

Detroit, Mich., Sept. 11.

FOUR ENTRANCES ON ONE SIDE OF A WINTER CASE

BY F. F. GEORGE

In my apiary I have 62 colonies of hybrid bees, 1 to 4 in a case, as shown in the engraving. The cases are packed in winter with a mixture of chaff and sawdust. I find that the hieroglyphics on the hive fronts do not prevent the bees from occasionally getting into the wrong hive.

The contracted entrances indicate new swarms. A dummy can be slipped from

George's packing-cases with the entrances all on one side.

Sweet clover that grew luxuriantly near a place where oats had been unloaded from a car, showing that the seed was mixed with the oats.

under the hive leaving a two-inch space for air. No swarms issued this season. The stake at the left holds a bundle of ripe mullein heads, which is my swarm-catcher.

The small hives in front are double-walled, and there are three apartments to hold nuclei for queen-raising.

Fraser, Idaho.

[If you had located your entrances on opposite sides of the cases, two on a side, we do not think you would have much trouble from bees getting into the wrong place.—Ed].

SWEET-CLOVER SEED IN OATS

BY GEORGE REX, JR.

The engraving shows a honey-plant which grows about 5 feet high, and branches out freely. It produces white flowers in profusion, which the bees simply swarm over. The flowers are very fragrant, and one can smell it from a distance.

I think it is something of a wild alfalfa clover. It grows at an old abandoned wharf, and covers about half an acre. I was informed that at this place western

oats were unloaded from the railroad, and that the seeds must have been in the oats. What do you think it is?

Stettlersville, Pa., July 24.

[Unless we are greatly mistaken this plant is the white sweet clover.—Ed.]

DO BEES LOSE THEIR STINGS WHEN THEY STING OTHER BEES?

BY L. P. HOLMES

An expression in the footnote to Dr. Miller's *Straw*, p. 540, struck me with surprise. It is that "worker bees sacrifice themselves as well as the drones" if they sting them. I thought it was an established fact that bees, in stinging others, do not lose their stings, consequently do not endanger their own lives. I ask now, for my own information, has any one ever seen the sting of one bee attached to another that has been stung to death? I never have. Among all the bees stung to death in robbing, and among queens that have been stung to death by other queens or by workers, I have never seen the sting of another bee attached to a dead one. I have seen a virgin queen, upon being introduced to

a stranger colony, seize three workers in succession and sting them to death, still retaining her sting. My observation of the process of stinging another bee has shown me in every instance that the point of attack aimed at is the small aperture in the thorax through which the viscera is connected with the abdomen. Unless this point can be penetrated by the sting, the attacked bee is apparently safe from harm.

It seems to be necessary for success that the attacking bee should get upon the victim's back. I have watched two queens fighting, and noticed that, when they clinch face to face, the hinder and middle legs are used very effectively to push away the opponent's sting, while using every effort to reach the vulnerable point at the waist. I once watched them fighting in this way for what seemed to me to be 15 minutes (I did not time them by my watch). They fought until exhausted, and quit for a rest. After a time they tried again with no result. In the third round one got upon the other's back, and the fight was at an end. If I am right on this point, a worker would run no risk to herself in stinging a drone.

Still, I incline to the belief expressed by the editor and Dr. Miller that the action of the workers toward the drones is in most cases, at least, a bluff. I have never, so far as I can remember, seen the drones curl up as the workers do when stung.

Frankfort, Kan.

[The sting of a queen is a little different from that of a worker, and it is probable that it is more easily withdrawn. It may be that workers are able to withdraw their stings when they sting other bees; but, nevertheless, there have been plenty of dead workers found with stings in their bodies. This, however, does not prove that the workers *always* lose their stings when stinging other bees. In fact, it is quite probable that they frequently do withdraw them. We should like to hear from others. —Ed.]

AN AVERAGE OF 103 POUNDS OF SUMAC COMB HONEY IN 14 DAYS

BY W. S. BASIM

The engraving shows a part of my beeyard (ground is too rough to get all colonies). This picture was taken July 4, 1911, at 4 P. M., when the honey-flow was nearly done. The tall hive holds a small colony guarding combs of honey.

My average yield was a fraction less than 103 lbs. of honey in 4 x 5 sections. The best yield ever before was 67 lbs. We had no clover last year, and this honey was almost all gathered in 14 days from sumac. I never had such a honey-flow since I have been in the bee business. No colony got the swarming fever.

Vincent, O.

Corner of W. S. Basim's apiary from which he secured an average of 103 sections of sumac honey per colony in 14 days.

Apiary of Clem Le Moine, Luton, Ia., that was nearly destroyed by a flood last spring.

APIARY NEARLY DESTROYED BY A FLOOD

BY CLEM LEMOINE

My apiary was nearly ruined by a flood last spring which entered in the cove. The picture shows some of the bees which were saved on April 23, 1912, when it was still very cold. This apiary had to be worked for increase only this season.

Luton, Ia., June 7.

THE CRAZE FOR COLOR

Breeding for Appearance has Resulted in a Poorer Strain of Italians

BY MAJOR SHALLARD

I have been asked which I prefer—the light Italians or the dark. My experience leads me to believe that there is no comparison. I think the dark leather-colored are as much ahead of the light goldens as a draft horse is ahead of a saddle back for plowing purposes.

Many years ago, when I first started beekeeping, somewhere about the time A. I. R. used to tell us all about Blue Eyes in GLEANINGS, I started to breed a race of utility bees based on dark leather-colored stock. After ten or twelve years of breeding from only those queens whose progeny showed marked ability to get honey, I had a breed of bees which I can since see were superlatively good. I did not appreciate just how good these bees were until the last few years. I got splendid crops, and my hives used to be always boiling over with bees. I did not care how dark a queen was as long as the markings on her progeny were even; but she

had to have certain qualities. First, her progeny had to be exceptionally good honey-getters; then she herself had to be large and well proportioned. She had to lay good plump eggs, and all in the same position in the cells. I get letters like this every now and then from old customers:

Send me another leather-colored queen. The last I had was a great honey-getter, and her daughters are just as good.

I have to return the money and tell them I have lost the breed. My output got so big that I started a bottling business in Sydney, and I had to leave the care of my bees to some one else.

Then the craze came in for golden Italians. I wish I had never seen them. I got some, and between carelessness on the part of my beekeeper, and breeding from golden stock, my choice breed of leather-colored bees was a thing of the past, almost before I recognized the fact. I have got back to the bees myself since, and I have tried many times to get a new start on dark leather-colored stock; but I have never succeeded. I have got leather-colored (?) queens from breeders many times, but they were all too light. It seems to me there are no leather-colored bees left; no one seems to have any. I do not know a single apiary where there are any of the old stock. I have walked through every apiary I know of, looking for the old sort, and have never found them. I have had beekeepers offer me any queen I liked in the apiary for nothing; and after looking at all the "golden beauties," I have come away without any. Now you will, perhaps, say that I am prejudiced. I am not. I am a man who cares nothing for looks, and that is all I think the goldens

have in their favor. I go strictly on utility.

I have had queen-buyers come to the yard and pick out a golden and take it away, against my advice to take a leather-colored queen that was really worth twice as much. It was the appearance and color that got them. They could not resist the looks. When I was a young fellow the Black Spanish fowl was the finest egg-layer one could get; but the fanciers started to breed "for feather," and they bred all the ability out of it, so that now as a breed it is completely ruined. My fixed opinion is that the same has been done for bees. It has been color, color, color, all along, and the business side has been lost sight of.

I was through the apiary some years ago of (I believe) the best queen-breeder in Australia, and he showed me 26 hives of his very choicest and best-bred bees. They were as gentle as so many flies; they were as golden as sovereigns; all the bees were evenly marked; but they were the laziest bees and the poorest honey-getters in the whole yard. He bred for color, and got his bees into the condition I told him he would, some years earlier. He had bred all the utility out in trying to breed color in.

You have something to say in the issue of June 1, p. 327, on five-banded stock. Of course, your remarks are right, to the extent that, if a man advertises five-banded stock, he should not send out four; but why do the people want five-banded stock? Would a ten-banded bee be any better than the old three-banded bees of the old Ligurian strain? My experience is that they are not half as good. I notice the gentleman eulogizes his golden drones. I never had any bee disease, or much, in my apiaries until I got golden drones. I have never had such big crops as before I got them. I believe the American breeders have done the industry a lot of harm, weakened the race of bees, and made them more liable to disease, and destroyed their honey-gathering qualities by the craze for color. The trouble is not irreparable. Go back to scratch and start fresh. Breed for the big dark three-banded fellows we used to have

Wilson's nursery and introducing-frame.

before the yellow craze came along, and all will be well.

Mororo, N. S. Wales, Australia.

[It is hardly necessary for us to state that Major Shallard almost echoes our experience. Some day the craze for color will give place to honey-gathering qualities.—Ed.]

A COMBINED NURSERY AND INTRODUCING FRAME

BY W. H. WILSON

The photo shows my queen nursery, which I find very useful in saving young queens. I also use it as an introducing medium. The young queens hatch out in the different apartments, where they find plenty of candy; and when I want to introduce one I simply open the port opening into the desired queen, and let the bees eat out the honey and release her.

Byesville, O.

[Queen nurseries are very convenient to have, especially if a lot of cells are ripe at the same time and there are not enough nuclei to go around. Under such circumstances the nursery acts as an overflow receptacle.—Ed.]

WHY DID THE EUROPEAN FOUL BROOD DISAPPEAR?

Did the Change of Feed Cure the Disease?

BY CHAS. S. SHARP

Late last summer I opened three of my hives with a hive-tool that I had used the day before in inspecting several colonies that were afflicted with European foul brood. I did not use the same hive-tool through ignorance, but through thoughtlessness. Two weeks later I thought I de-

tested symptoms of European foul brood. A week later my suspicions were confirmed. The disease did not become extremely bad, owing to the honey-flow from golden-rod and aster; but it was very noticeable on all the combs of each of the three hives. About the first of October I extracted every drop of honey from those hives and started to feed a little sugar syrup for a few nights until I could get some cut loaf sugar from down town. I put a super on top of the hive and dumped in ten pounds of cut loaf sugar all over the top of the frames, placed a piece of burlap on top of the sugar, and filled the super with sawdust. This spring, as soon as they would take syrup, I commenced to feed them and took off the cube sugar that remained (about three pounds each). These colonies are strong and vigorous, and up to date do not show a sign or symptom of European foul brood.

The point I wish to raise is this: Is this method or plan a cure for the disease when it is contracted too late in the season to attempt to cure by shaking? As I haven't any afflicted colonies I am unable to carry the experiment any further this year, and I am very certain I do not intend to procure any diseased colonies to satisfy my curiosity.

I wish three or four of the older beekeepers would try this plan, and let us hear the result next spring; but I would caution the beginner not to try it, for the mere fact that it appears in GLEANINGS does not prove it is a sure cure.

Newark, N. J., Sept. 7.

[We question whether your procedure in the above case cured the disease. European foul brood is an elusive trouble which sometimes disappears during a honey-flow without any treatment whatever. Perhaps when you extracted all the honey and commenced feeding the sugar syrup you imitated a honey-flow and encouraged the bees to "clean house." Getting rid of the honey would seem to be a good thing, although enough of it would remain in the cells, probably, to transmit the disease were the conditions favorable. And there are some plans for treating European foul brood in which the honey is not taken away at all, such as the Alexander plan for instance. We are not saying that the disease in your case would have disappeared of itself, but we merely wish to make the point that it often does, so that beekeepers are sometimes deceived in supposing that some manipulation accounts for the disappearance, when in reality the bees merely clean house themselves.—ED.]

Different forms of the stand.

AN IRON HIVE-STAND

BY WM. RICHARDSON

I am sending you a picture of five different styles of hive stands, the last form of which I already have in use as shown in the second picture. As you can see, they are to be pushed down into the ground as far as the first projection. I do not think they would be too expensive.

Culleoka, Tenn.

[The first expense of the hive-stands would be pretty high, we are afraid; and then there would be the cost of transportation, which would be a rather big item for a large apiary especially. There would be room for the toes of the feet under the hive, which would be quite an advantage, although it would seem to us that four wooden stakes would be nearly as durable, and would be much less expensive.—ED.]

Richardson's iron hive-stand in use.

A NEW RECORD SYSTEM

How to Make Abbreviations and Signs Tell a Long Story

BY ARTHUR C. MILLER

To the making of record systems there seems to be no end; and, lest the end should be approaching, it is the writer's purpose to postpone its arrival by describing a new one.

There are three different classes of records—one for the man who is raising queens, one for the man who is increasing and building up colonies, and one for the busy honey-producer. The first is so radically apart from the other two that it should begin and remain a separate affair. Of a necessity it will differ from each system of queen-rearing and with each individual's methods.

The others, however, naturally merge one into the other, for the man making increase may be and quite likely is raising honey in the same yard, so a system should be elastic enough to cover both of these branches of apiculture.

This granted, the next question is, "What shall be recorded?" This should be answered Yankee fashion, "What is the record to be used for?" To save time. To reduce cost of operation. Then it must be simple, easy to make, and at a glance convey all the information needful in the rapid handling of colonies. At this point the need of some way of designating each colony presents itself. Numbers here as in so many other lines of human endeavor will be found to be the best. But numbers permitted to run riot are often most troublesome; so, to restrain them they must be grouped, which is another plan used in many places. As hives are not infrequently moved in some apiaries, and as such moving would cause endless confusion were the hives numbered, the stands should bear the numbers and the hive (colony) be known only by the place it occupies. This granted, the grouping of the numbers in the apiary must be considered. For the sake of clearness an apiary for 200 colonies will be used as an example. The yard is so shaped that we can have four rows of hives with fifty in a row. That makes the numbering look easier until we look for number 63, or almost any number except the ends, and those will bother unless the numbering is begun correctly. The rows must be broken up into shorter lengths, and ten makes a good and readily countable group. Furthermore, the hives may be set in pairs in each group. The numbering is beginning to take form;

but, stop a minute. The first group must have only nine hives; i. e., from 1 to 9 inclusive; the next has ten; i. e., 10 to 19 inclusive; the next has from 20 to 29, and so on. Why? Because when we look for 40 it must be in the group with the rest of the forties, not in the end of the group of the thirties, as it would be if our first group ran from 1 to 10 inclusive. This is a seemingly trivial matter; but just juggle with figures grouped in each way and see the difference. Or look at this diagram and see how readily any number may be located. (For the sake of brevity only the terminal numbers of each group are given here.)

1 - 9	10-19	20-29	30-39	40-49
50-59	60-69	70-79	80-89	90-99
100-109	110-119	120-129	130-139	140-149
150-159	160-169	170-179	180-189	190-199

No matter where one stands in the apiary, any desired number is quickly spotted. The record-book must be arranged in the same way—that is to say, each page should embrace a group of ten, the first page, however, having only nine.

Now we have reached a point where we can consider the nature and the form of the entries. Four cardinal points are to be considered, and every part of the bee culture, aside from queen-rearing, has to do with one or more of them. First: Condition of the colony as a whole. That is to say, is it a top-notcher for the time of year, or one degree less, or two degrees less? To illustrate: The top-notcher in May is a colony that is big enough for section work. The one a degree lower will do well for extracted honey, but is not quite strong enough for sections. The next-degree colonies will come up to a producing grade before the flow is over, or at once if helped from some other colony. So we can grade our colonies as 1, 2, and 3, and W, the W standing for "weak."

Later we want to know if the colony has swarmed, a swarm is expected, or is to be forced.

The second point is the queen. Who is she? How old is she? or is she missing? and if so, what is taking her place as a cell, a virgin, laying workers, or larvæ given for a queen to be raised from.

The third point has more particularly to do with increase or with building up colonies in the spring, and it is embraced in the word "brood." How many frames of

it are there? or how many are to be or have been added or taken away?

The fourth and final point is food. "Food" is more comprehensive than "stores" or "honey," for they are food. And we may have to give or take food or honey from a colony, and the food given may be honey or syrup, and honey taken may be for other colonies or surplus for ourselves.

We will arrange the four points in a group like this:

C	B
Q	F

"C" is for the condition of the colony as a whole. "Q" is for any thing relating to queens. "B" is for any thing relating to brood and bees. "F" is for any thing relating to food or crop.

If, now, we can get a set of simple signs to use in these squares, we have only to put the proper one in the proper square to tell us what it might take a dozen words to write out in long hand. And eight well known signs plus a few letters do it all. The signs are o, +, —, X, ÷, ?, >, <, √.

Nothing to learn about those, surely, unless, perhaps, the "arrow head," which is used for "to" or "from," and will be explained later. Three other items must be provided for, namely, the date, and whether a thing has been done or is to be done. If the date is properly handled it will tell the other two.

With this somewhat long preamble we come to the record system itself; and in laying it before you I wish to

say that it was not "invented," but was the slow outgrowth from countless efforts to secure the end now attained.

The following illustration is arranged to show some of the many points the record can cover.

The first column carries the colony numbers. The top of each column carries the date the record was made, i. e., colonies inspected, and the indicated condition found or the indicated work done.

	In 5	In 20	Pl 1						
20	1 -2 1911 H×M +10 Fd		#						
21	1 +10 1911 S×M Fd								
22	2 +10 1911 M C	-3	-2						
23	w +2 1911 M	Rq 1 St. +1	? ✓						
24	1 + 1911 H×M 2CS	?							
25	3 1911 H×Bk	>29	5						
26	1 + 1910 H 2E×S	? +1E×S							
27	N V	? lg							
28	20 1911 S×H	÷ > 48							
29	w +2 1911 Y	5 >							

8 In.

5 In.

A description of these records will make the operation of the system plain.

On June 5, colony No. 20 is in No. 1 condition. The queen was from stock designated as "H," mated by a drone from stock designated as "M" and raised in 1911. Two frames of brood were taken, as shown by the "2" in the "brood" square. Ten frames of foundation were given in an upper story, as shown by + 10 fd. in the "food" square. This is taking a little liberty with the use of the title "food," but it is furnishing food-storage capacity, or brood space if the queen goes up. But despite the liberty, no mistake can be made in future reference to it. If it is especially desired to differentiate between foundation or combs above an excluder and those to which the queen has access, it may be shown as at No. 21, where the characters are placed across the horizontal line between the "brood" and "food" squares. If this plan is followed, then the record at No. 20 would mean that the foundations were above an excluder.

No. 22. Here we have a "Grade 2" colony, and it was given ten combs to which the queen was allowed access.

No. 23 was weak, and was given two frames of brood. The queen was of the strain designated as "M," and as no mating is shown it is understood she is mated to a drone of the same strain.

No. 24 was of "Grade 1," and was given two comb-honey supers.

No. 25 was "Weak;" had a queen of the "H" strain mated to a black drone.

No. 26 was of "Grade 1," had a 1910 queen, and was given two extracting-supers.

No. 27, a nucleus with a virgin queen.

No. 28, a "Grade 1," but has twenty frames occupied. Not having any plus sign before the number 20, in "B-F" squares, means that the condition existed when examined.

No. 29 was weak; had a queen of a strain designated as "Y;" usually the initial of the person from whom queen or strain was purchased is used.

In the next column, under date of June 20, we find a — sign in the "food" square, and two diagonal lines through it. The — sign was put there either June 15 or some time before the apiary was visited on the 20th. It meant that combs of honey ("food") could be drawn from that colony. None were drawn, so the sign was canceled by the two diagonal marks. That is quicker than erasing.

No. 21 was not opened.

No. 22 had three frames of brood and

two of honey taken. It goes without saying, that the places were filled with combs or foundation, so no memorandum to that effect is needed.

No. 23, in the "queen" square, is marked "Rq," put there probably June 23, to show that the colony should be requeened when a queen was available. This was done on the 25th, as shown by the "I St.," meaning that a queen from "Stewart" stock was introduced. (It is the writer's practice to dequeen and requeen at the same time.)

No. 24 shows a question-mark in the "Food" square, meaning that the "Food" condition should be inspected. This was done and everything found satisfactory, as shown by the check mark "✓."

No. 25 was removed to stand 29, and the two vertical lines stop the record.

No. 26 has a question-mark in the "food" (honey) square. Inspection made and one super taken off, and an empty one put on.

No. 27, queen square has the question-mark. The queen was found to be laying, as shown by the "lg."

No. 28 was marked for division, which was done, as indicated by the >48 in connection with the ÷ sign. The 48 was the stand number to which the removed part of 28 was taken.

No. 29 had No. 25 added to it. Of course, the poor queen of No. 25 was disposed of, and it is unnecessary to say it. If both queens were left to fight it out, "a?" would be put in the "queen" square of the next column, and at the next visit the queen condition of that colony would be ascertained.

On July 1st we find but two entries in this column. No. 23 was looked at for queen condition, and the new queen was found to be all right, as shown by the check mark "✓."

No. 24. A swarm was hived here; not known where it came from, as shown by the question-mark in the "queen" square.

The next column is marked for the work to be done on the next visit.

Apparently the yard is being run largely for increase. No. 20 can have honey taken from it. No. 21 can spare both honey and brood; No. 22 the same. No. 23 should have brood added. No. 24 will probably have supers to come off. No. 25, the swarm of July 1 needs to be considered generally; hence the question-mark in the center. No. 26, supers should be examined. No. 27, both brood and honey to be added. No. 29 asks, "How does brood and food stand since the union?"

Suppose it is July 10, when the next inspection is made. If combs of brood or

food are taken or added, the number of combs so used is placed beside the minus or plus sign. When through, the date is written at the top of the column, and the record is complete.

Placing the signs in the undated column is for work to be done. Putting the date at the top of the column says it *has* been done. An omission of indicated work is fixed by canceling the indication.

Only one caution is necessary, and that has to do with the use of letters. Try to use such as can not be interpreted in two or more different ways. For example, + 2 S in the "food" square might mean two supers added, either "comb" or "extracted," or it might be read as two pounds of syrup given. Hence, the "S" must be qualified by "C" or "Ex," for the different supers, and by "lb. Sy" for pounds of syrup. These features will quickly reveal themselves, but it is better to know them first and start right.

The records are best kept on loose leaves of stiff paper or cardboard held in thin tough covers by pieces of tape or string passed through the holes. Five cards will hold the records for 99 colonies. Usually the six columns will suffice for a season's work, when honey only is worked for; but when working for increase by building up nuclei, more room is needed; and in that case records are carried forward to new cards, when the earlier sets become filled. The carrying forward is simple, however, for all one needs is the grade number in the "colony" square, the queen's record in the "queen" square, and the nature of the work to be done or feature to be inspected on the next visit; and in actual practice I find a page (ten colonies) can be transferred in about three minutes, less for honey-producing colonies, more for colonies which have been built up, because then the grade has to be estimated from the additions. Sometimes it is easier with these colonies merely to transfer the queen record and indicate the work probably needed, leaving the "grade" to be filled in the "colony" square when the colony is inspected.

The lines on the cards are printed, as printer's ink will not blur if wet, as do lines ruled on. The printing is cheap, as only parallel lines are set up, and then the cards are run through the press twice for each side, the second time the cards being run through at right angles to what they were at first. This gives the squares.

A black leadpencil is used for the records, as it will not blur if wet; and, by

using one of the right quality the records will not smut.

To give the system a trial, any one can easily make up a few sheets after the design shown, and follow the instructions, varying them, if he wishes to suit his own particular conditions or desires. It has fulfilled every need with me, and has served me no end of time, labor, and thought. I can heartily recommend it.

Providence, R. I., Aug. 12.

EXCESSIVE SWARMING IN AUGUST

BY S. A. FULLER

I have been having the time of my life for the last three weeks with my 150 colonies, for they have been swarming. On Aug. 1 I extracted and cleaned up comb-honey supers especially to make room, and they certainly had no lack of room. When the first swarm came out I opened the hive and cut out all queen-cells, put the swarm back where it came from, and put a queen-trap at the entrance. I went through all my hives and cut out queen-cells when started, and put on all the traps that I had. But they swarmed just the same. I had four large swarms go together—three from trapped hives and one from a hive having no trap. I cut cells out of one hive three times, and yet these bees swarmed twice. Three times a day for two weeks I put them back every time (I have a queen-trap on this one), and still they come. I had four swarms that were so large (several swarms together) that I had to put them in barrels.

The fall flow is on now from horsemint and goldenrod; but so much swarming will cost me the surplus. I should like to see the color of the man's hair who could keep these bees from swarming this season. Up to now my bees have done better this year than ever before.

I now believe if I had extracted Aug. 1 from the brood-nest I could have prevented this swarming; but it is too late to talk about it now. Any way, next year I shall try to avoid it. Having bees in this country in August is "something fierce."

Helena, Ark., Aug. 8.

Bees Stinging Drones of Queenless Colony

On page 540, Sept. 1, in reply to Dr. Miller's query, "Do bees sting drones?" you remark that you have never seen them do so. This fall, after the frost has killed the flowers, unite a colony that is queenless, and has lots of drones, with a colony that has a queen, and observe the bees stinging the drones by the hundred. This is the only condition under which I have seen them sting drones; but I have seen this many times.

PAUL SCHEURING.

Heads of Grain from Different Fields

Beginner's Questions

1. Must there be two queens to swarm?
2. How may honey be extracted from frames? I have only a few colonies and do not want to buy an extractor.
3. Do bees breed all the year?
4. How many frames of honey should be left in a good strong hive for wintering?
5. How often should one inspect his hive to see if all is going well?
6. If the comb in frames is old, should it be cut out and let them build fresh comb? What is the best time to do this? How often should it be done?
7. What will the bees do when all the frames and supers are full?
8. This year I bought a hive with bees in it; and when it arrived the supers were in a box with some bag cloth over one end. What is this for?
9. What months are the best for honey?

Philadelphia, Pa., July 1. J. SWEENEY.

[1. When a prime swarm—that is, the first swarm of a normal colony in a season, issues, it is accompanied by the old queen, and there is left for the parent colony, so called, ripe queen-cells from which will come a virgin which, after being mated, will become the mother of the colony.

2. It is difficult to extract honey from frames without a honey-extractor. You can shave the cappings off, place the comb in a horizontal position in a warm room, and drain the honey out, turning first one side and then the other to the screen on which the comb rests, but this is a slow process, and you can not get all the honey out.

3. In some localities there is more or less brood-rearing going on nearly the whole year; but in your locality the queen slows up on egg-laying after the main honey-flow is over, and, by early fall, has almost or entirely ceased. At such times she may be stimulated to further egg-laying by stimulative feeding, so as to make sure of a good force of young bees to go into winter quarters. Colonies wintered in a cellar are unlikely to begin brood-rearing along in the spring, while those wintered outdoors in your locality probably would not begin before March.

4. There is no definite number of frames of honey that should be left for a colony during the winter, for it depends upon the strength of the colony and also upon the place where the colony is wintered as to how much honey is needed. For a colony wintered in a packed hive outdoors, from 20 to 25 pounds should be left in the hive, and this means that there should be some honey in the upper part of the combs with considerably more in the outside combs on each side. Perhaps three inches of honey in the upper parts of the central combs would be sufficient, provided the two outside combs on each side were nearly full.

5. Do not open a hive oftener than is necessary; that is, do not open unless you have reason to think something is wrong or needs your attention.

6. If the comb is straight and good, with but very few drone-cells, there is no particular need of renewing it unless there is danger of disease lurking in it. The fact that it is old and black makes no particular difference, for this color always comes after a few generations of brood have been reared.

7. If all the available space for storing honey in the brood-chamber and super is taken up, the bees will probably hang out on the front of the hive, and will very likely cast a swarm a little later. Such a condition of affairs is conducive to swarming. It is needless to say that such a state of affairs should be prevented.

8. We can not say what this box covered with burlap is used for. Very likely it is merely a receptacle to keep the bees away from the supers. If it is a shallow box, it may be the chaff tray for use in winter.

9. If you mean what months are the best for the secretion of nectar, we will say that this will depend considerably upon your individual locality. If you depend mainly on white clover, we will say that in the latter part of June you will get your main honey-flow. If you have other honey-producing plants coming later, such as buckwheat, gol-

denrod, aster, etc., then these will come in their own seasons. The best way to find out particulars in this respect is to inquire of some old beekeeper living near you.—ED.]

Building a Support for Packing Over a Row of Hives

When getting ready to pack my bees for winter I build a board wall about three feet high, then place my hives on their summer stands in front of this wall side by side, leaving about four inches of space between the back of the hives and wall, and place the hives as close as they will stand and yet have room to work packing between them. I then use a ten-inch board to make a shelter in front, securing it near the top of the homestead, giving a slope sufficient to run the water off; and from this board I build up high enough so that, when the roof is on, it will slope back.

In placing the bees I leave the super on, and use a burlap or something of that kind to cover the bees; but under this I place two or three small corn-cobs across the frames half an inch apart. This gives the bees free access to all the stores. I fill the supers with oat chaff, put on the cover, and then fill the space back of and between, and in front and above, with autumn leaves well packed in, and then put on the roof. Now they stand facing the east, all well protected except in front of the homestead, and that sheltered with a ten-inch board.

I fill the space under this board with straw well packed in. This gives ventilation, keeps out the snow, and is easily removed at any time when the mercury runs up to 45; and the straw scattered out in front of them makes a good alighting-place. When spring comes it is safe to leave them in their winter quarters until severe weather is over.

I have tried wintering in the cellar, but do not have as good success as with the above plan. Milo, Iowa. B. A. MANLEY.

Bees of a Laying-worker Colony Desert Their Own Combs for Combs Having a Laying Queen

With reference to your reply to F. B. Fenner, Aug. 15, p. 523, I should like to relate my experience with "laying workers." I had two strong colonies with laying workers. After trying unsuccessfully three times to introduce queens I took a laying queen with two of her own frames of brood and bees, and placed her in an empty body (filling up the extra space with empty combs); then I put this body with the frames over one of the colonies of laying workers, using an empty body between the laying workers and the new queen. It was not long before the laying-worker colony deserted the combs and joined forces with the new queen. This experiment proved successful in case of both colonies. It is possible that a queen-cell would do instead of the laying queen; but I can not vouch for it, as I have not had a colony of laying workers to experiment with since the two mentioned above.

Calabasas, Cal., Sept. 3. JAMES K. HEDSTROM.

Brood that Hatched in Spite of Having Been Under Water

I have noticed some reference lately to the amount of cold that brood will stand without chilling. I had some experience this summer along that line that indicates to me that it will stand considerable.

On the night of July 21 a big thunderstorm passed over here, and it rained heavily—so heavily that the irrigation ditch overflowed. Our bees happened to be so located that about 20 colonies became flooded, a number of them being under water nearly to the top of the brood-frames. As there were supers on most of the hives the bees managed to keep above water. However, the strange part of it is, this brood that must have been several hours under water did not get chilled, for I found only a very few larvae carried out. Most of the brood was capped, and it hatched all right. One colony that was nearly submerged has made

four supers of honey since, which it could hardly have done had it lost all of its brood at the beginning of the honey-flow. It was in a Danzen-laker hive, and the brood was practically all covered. It was about 7:30 in the morning when I discovered that they were under water. I carried them out and cleared out the water as best I could. I fully expected that all of the submerged brood would die, and was happily surprised on later examination to find it all good. I did not think to take the temperature of the water that morning, but did on the following morning, when I think it was about the same. It then stood at 56 degrees F. The ditch had ceased overflowing when I discovered the calamity; and as the storm-rassed over just before midnight I am certain the lower part of the brood, at least, must have been under water for some time.

Ogden, Utah, Sept. 2. JOSEPH H. PETERSON.

Getting Rid of Laying Workers with a Bee-escape

It is not difficult to cure a colony of laying workers if they are taken soon after they have begun their work—that is, within four or five days after the first eggs have appeared. If a couple of frames of young brood, with the adhering bees, are given, queen-cells will almost invariably be started. It is well not to allow these to hatch, for the queen will almost certainly be inferior, so they may be replaced after two or three days by a ripe cell. A queen will often be accepted at this stage, but I have found introduction risky.

But when the laying workers have been allowed to go for ten days or more, so that the combs are filled with drone brood in all sorts of scattering stages, a cure may be said to be impossible, so far as making the colony of any use within a reasonable time. Under these circumstances the bees will seldom accept a queen if offered in any usual way, and the combs are too full of worthless brood any way to allow a queen to lay.

The result of a good many experiments in the past two years has led me to fix on the following plan, which has never yet failed me. A two-frame nucleus is made from a normal colony, and a queen introduced, or a very weak colony may be used instead of this nucleus, if there is one which needs strengthening. The laying-worker colony is set on a bee-escape board over the nucleus. That is all. In the course of four or five days, four-fifths of the abnormal bees will have gone down, one by one, and will have united themselves quietly with the nucleus. The few bees left above I have always fancied to be the laying workers themselves; but they do no harm if knocked out on the grass. The sealed drone brood is then uncapped, and left to chill over right. It may then be given back to the bees, which will clean out the dead larvae.

Stouffville, Ontario, Can.

F. L. POLLOCK.

A Burlap Awning in front of the Hive as a Shelter from the Sun or Snow

My method for a few years past has been to fill the super with good absorbents, such as sawdust, leaves, or excelsior, and to wrap the hive with heavy building paper well tacked on frame top to bottom, leaving the full entrance open. For a shield from snow or wind, I tack burlap along the top of the front of the hive, letting it drop over the entrance. In case of a single-walled hive, more paper can be put on and fastened with thin slats.

When the sun shines on the front of the hive, it shields the light from the bees. When warm enough for them to fly I throw the sack on top of the hive and drop it down as needed. I find it the best front protection, in my experience of fifty-two years in handling bees.

Conesus, N. Y.

D. W. TRESKOTT.

Living up to Their Name

In buying old lumber last winter I came into possession of a beer sign which I sawed and made into a hive with the big letters on the outside of the hive. Never have I had bees work as busily as this colony; for when they were put into this hive on the first day of June they had neither comb nor foundation. I was about to advise others to use saloon and beer signs for hives, when, hap-

pening to look into the brood-nest, it was plain that these bees had been doing crooked work from the very first. The combs were all crosswise and cornerwise. Would it be well to use brimstone at once, or will they do straight work another year if foundation is put into a new hive, and the beer sign removed?

Chelan Falls, Wash. Sept. 11. C. B. JACKSON.

[We would advise you to give the bees another chance. May be they will reform if you start them right once more next spring.—ED.]

A Good Record Made by an Eighty-year-old Bee-keeper

When I started this spring I had thirty-six colonies of bees. As soon as they began to have three or four combs of brood I began dividing them, making increase following Mr. Doolittle's plan as well as schemes of others, and also drawing on my own fifty years of experience.

I extracted over ten barrels of honey, and besides this I have about 1000 lbs. of comb honey in plain sections. I did all of our work myself in spite of the fact that I was eighty years old the second of May. I am very busy now getting it ready for market. We have a very good home market here, and I think I will sell it all in jelly-glasses and Mason jars.

Newcastle, Neb.

A. C. BUTLER.

What a Three-frame Nucleus did on a Peninsula 1½ Miles Wide

The first of last June I purchased a three-frame nucleus and an observation hive. The bees entered the super on the first of August, and up to the present time I have obtained 56 pounds of comb honey. Besides this I should judge that there are from thirty to forty pounds of honey in the brood-chamber, and the little chaps are still hard at work. It seems to me that this is a good showing. There is very little farming here—no buckwheat or basswood, and we are on a peninsula not over 1½ miles wide.

Wood's Hole, Mass., Sept. 20. W. K. BUTLER.

Feeding in Cold Weather

Have any of your correspondents ever tried feeding in midwinter? Last winter I fed small quantities of syrup in January, February, and March, when the ground was covered with snow, and when the temperature was far below freezing. I never before had bees come out in as good shape in the spring. One colony stored about 15 pounds of honey from fruit bloom. I did not lose over 500 bees all together by flying out and freezing.

Kansas City, Kans.

D. D. DOWNING.

[If syrup is fed hot right over the cluster, the bees can take it in cold weather. Sometimes, if the weather warms up a little they can take cold syrup. But in either case, feeding syrup in cold weather is of doubtful value, since it tends to excite the bees, causing them to expand the cluster unduly, etc. We should say that your experience is the exception that proves the rule.—ED.]

Bee Demonstration to Swell the Membership of an Association

The farmers of upper Bucks County, Pennsylvania, held a two-days' picnic on the 6th and 7th of September. On those two days I made demonstrations of modern methods of beekeeping, using a wire cage, and this feature proved both profitable and entertaining, for several hundred people surrounded the cage whenever I entered it. The demonstrations stimulated beekeeping, and they were the means of bringing a number of new members into the Bucks County Association.

Richlandtown, Pa.

An Escape-board for Uniting Colonies

Aug. 1, p. 491, mention is made of the paper method of uniting bees. This is my plan: After taking the escape from an escape-board I place the board over one colony of bees and pour upon it half a pint of honey or thick syrup. Then I set the other hive on top.

Our Homes

A. I. ROOT

Be not unequally yoked together.—II. COR. 6:14.
Your adversary the devil, as a roaring lion, walketh about, seeking whom he may devour.—I. PETER 5:8.

Come unto me, all ye that labor and are heavy laden, and I will give you rest. Take my yoke upon you, and learn of me; for I am meek and lowly in heart; and ye shall find rest unto your souls. For my yoke is easy and my burden is light.—MATT. 11:28-30.

A BEEKEEPER IN TROUBLE.

The following letter somewhat explains itself:

Mr. A. I. Root:—I am in great trouble, and in jail on account of not being able to pay alimony to my divorced wife. This is an attempt to take my pension money away from me. I have had 12 dollars a month up till a few days ago, when it was increased to 30 dollars a month. They took ten dollars a month out of the twelve dollars for some time, till I had to sell my horse and cow to keep my two little boys and myself, and I am about \$500 in debt. I send you book and paper under other two covers, which will give you an outline of the case.

Sept. 10.

J. E. C.

The book sent me, referred to in the above, is about the size of GLEANINGS, and contains 59 pages. These 59 pages contain full details that need not and should not have been allowed to get into print at all, as they refer only to neighborhood quarrels between relatives and neighbors. Why in the world our good friend should have ever gone to the trouble of putting such matters in *print* is more than I can explain. Notwithstanding his statement that he is a poor man, and has had to sell his horse and cows, and part with his two little boys, in a letter in a local paper which he sends, he says he is working hard to get money enough to buy a gas-engine to run his extractor. He says his right arm is partly paralyzed by turning the extractor to extract so much honey. Now, my opinion is that turning the extractor has had but little to do with it. His nervous condition from dwelling so much on his quarrels with his wife and neighbors has brought on paralysis, and no wonder. Let me quote briefly from the first page of this book:

AN EXPOSE; A TRUTHFUL STATEMENT OF MY ACOQUAINTANCE, MARRIAGE, AND DIVORCE FROM
MAY E. SMITH.

In the spring and early summer of 1892 Miss May E. Smith came to my place repeatedly after a quart of honey vinegar. She had called herself Miss Chase to me; and, in fact, I did not learn her true name until, speaking to a schoolmate of hers and calling her Miss Chase, he said to me, "Her name is not Chase, her name is Smith." Yet I thought for some time after that she was Mrs. Chase's daughter by a former marriage. Certainly she had lived in Medford over four years when this took place, but my attention had never been called to her. I took her to be about fourteen years of age in the short dresses she wore.

I can tell you I was considerably surprised when she told me she was twenty years old.

I was forty-eight years old at that time, and was not interested in any girl so young, only to

treat them respectfully. But there was a persistency in her attentions and treatment of myself that would have taken an indomitable "I will not" to counteract, and thus I was led, forced, against my own best judgment into a marriage with this too young person, by and with the help of Mrs. W. S. Chase, a lady for whom I had the greatest respect at that time. I want to say right here that this marriage was the mistake of my life. I have my faults, as we all do. I am afraid of the person that has no faults; but can we not cut them out, nor make them grow less. I can stand a lot; my shoulders are broad; but surely my punishment for this marriage is too grievous. They have kidnapped my children, my pets, my darlings, my babies, out of the nice little home which I had provided for them, and left me bereft of my jewels in my old age, and this is a crime for filthy lucre, and nothing else, or why did they resort to perjury and fraud to accomplish this vile scheme! Three sisters perjured themselves—Amanda Smith Cady testifying that I drew a big revolver on her and her father. This is false.

A man 48 years old was unwise enough to get married to a little girl wearing short dresses. She claimed to be 20, but Mr. C. thinks she was only about 14. Of course it was a big blunder to contract such a marriage in the first place. But after it was all "said and done," and especially after there were some *children* given them, friend C. needed the grace of God in his heart if anybody *ever* did. A genuine Christian man—one who is full of the patience and forbearance of the Lord Jesus Christ, would get along with a wife, even in her teens, and the divorcee he speaks of, I feel sure, was entirely wrong and out of place.

Dropping for the present the case before us, let us consider a little this matter of old men marrying young girls. I need not make particular mention of the millionaires who have quite recently divorced the wives of their early manhood, in order to marry a young girl—generally an actress. In fact, I have feared there are giddy and unscrupulous young girls who set about a course of training in order to capture or captivate some old man who happened to be rich; and I have watched as well as I could the results of such marriages. The young girl not only soon gets sick of her bargain, but the foolish (and, I might almost say, the idiotic) old man in a like manner would be exceedingly glad to get back to his first wife—the faithful companion, perhaps, for forty years or more, if it could be done. The divorced wife frequently had nearly or quite as much to do in accumulating the riches as the millionaire himself; and yet after the divorcee she is put off with a mere pittance. Let me suggest to you John Jacob Astor, who recently died in the Titanic. In his will the faithful old wife was comparatively unrecognized,

while the young actress succeeded in scooping in several millions; and now there is a jangle about the millions that are to go to the baby only a few weeks old. If this thing is allowed to go on—this thing of letting a man go scot free or letting him trample the most holy and sacred laws (of both God and man) under foot, *because* he is a millionaire—we shall have something *worse* than “race suicide.”

Now, our beekeeping friend is by no means a millionaire; and this kind of sin is by no means confined to millionaires. How many times do we see old men acting silly around young girls—perhaps girls in short dresses! And, by the way, the short dresses of late do not seem to be confined entirely to girls in their teens, as used to be the custom and fashion. May God help us, or may he help us who claim to belong to the Lord Jesus Christ, to do all we can to put a brake on the work of that “roaring lion” who is just now particularly active in going about “seeking whom he may devour.” I suppose that, in every community, there are more or less old men, both married and unmarried, who act silly around young girls—especially if these young girls are full of life and attired in modern styles.

I am now going to come *still nearer* home. May God help me, the author of these Home papers, to beware how I take more notice of the bright young girls who are flitting around me like butterflies, than I do of the young boys who are just as nice and just as bright. Some time ago I made the remark that I really enjoyed being near the entrance of our factory (just before the whistle blows) and looking into the bright faces of our employees, and saying “good morning” to each and every one. I think I happened to remark that I especially liked to catch the eyes of the bright young boys as they come to their work exactly on time. While I was speaking, somebody in the crowd—I do not know but it was one of my daughters-in-law—looked up mischievously and asked me if I did not *particularly* enjoy saying “good morning” to the good-looking and nicely dressed young girls who work in the honey-room, the various offices, and in the packing-rooms of our establishment. There was a big laugh all around at this sally; and when I came to look into my own heart I confess I felt a little guilty. May God in his great mercy help me to keep even more closely in that straight and narrow way, and to look on all mankind even as did the dear Savior when he said, “He that doeth the will of

my Father, the same is my brother and my sister and my mother.”

Now, the old *men* are not altogether to blame in this matter. There are middle-aged and even elderly women who act foolishly around young boys. Years ago one of the first converts it was my privilege to lead to the Lord Jesus Christ made an abrupt change in his life. He deliberately *did* come “out of darkness” and get into the broad daylight of the gospel, and into a full trust in God’s promises. Christian people right and left extended to him a helping hand and bade him Godspeed in the new way. Among them was a woman prominent in Christian work. She took so *much* notice of him, and made so much of him, that I began to protest. I feared the boy might be spoiled by her overdoing. She excused herself by saying, “Why, Mr. Root, I am old enough to be his mother, and I am only taking a ‘motherly’ interest in him.” Her good husband was a beautiful example of Christian manhood. He, too, took an interest in the boy who had dropped his tobacco, profanity, strong drink, evil companions, and every thing else, and was a real friend to the boy. I cautioned the *boy* as well as her who wanted to be a “mother” to him. Finally the young man came to me and told me his troubles. This motherly woman had —. Then my young friend said something like this:

“Mr. Root, if there ever was a good man it is this woman’s husband; and I would rather die than harm him or his domestic relations by thought or deed. It will not *do* for me to be where I shall see this woman any longer or have any thing to do with her.”

May God be praised, this young man, by my advice, heeded that part of the Lord’s prayer where it says, “Lead us not into temptation, but deliver us from evil.” It is right and proper that elderly people should notice the boys and girls, lend them a helping hand, and watch over them in a fatherly and a motherly way; but whenever you are tempted to go further than that, remember the caution from your old friend in this Home paper.

Our beekeeping friend suggests that there was “a persistency in her attentions and treatment.” Now, girls of fourteen or fifteen often jest with, and banter elderly people with whom they are well acquainted, without a thought of any thing wrong.*

* A very good friend of mine, years ago, took me “Down East” to his old paternal home. He was very anxious that I should become acquainted with his father and mother and a younger sister. This sister was particularly bright and full of

I have more fear of the designing mothers back of the young girls than I have of young girls fourteen or fifteen. We should each and all of us, especially we men folks, pray constantly for grace and strength and wisdom to treat all young girls, wherever we see them, exactly as we would have all men treat our own daughters. This is sometimes a hard thing to do, I know, especially if all men are created much after the same pattern as myself. But you know the promise in God's word, "My grace is sufficient for you," and, again, "He will not suffer you to be tempted above what ye are able to bear."

Now comes in one more thought, and it is a most important matter. Old men and perhaps young men are in this present day and age, many of them, employing bright young girls as stenographers; and oftentimes these stenographers are shut up with the employer in his office away up many stories high. *I would not have it.* May be you will think I am old-fashioned and over cautious, but I *know* whereof I speak. Granting, if you choose, that there are hundreds and thousands of good girls earning their bread in this way, the fact still remains they are making a precedent and at the same time setting a bad example. A nephew of mine is a skillful physician. When girls go to his office for counsel he tells them that they must bring their mothers along; or if that is not convenient his good wife is called into the room, and she remains there until whatever must be said and done is ended; and may God be praised that I *do* know of *one* such family doctor. Now let us have society so framed that it will be generally understood that it is not exactly the thing for a man and woman who are not related to each other to be kept much together. As a rule I deprecate gossip; but my good pastor, Rev. A. T. Reed, years ago, said that, when things of this kind are going on, people *ought* to talk, and he said he was often glad that they *did*.

Not very long ago a banker with whom I am acquainted was talking about getting

life. My friend took particular pains to have us two become acquainted. During my stay of two or three days we became so *well* acquainted that my friend suggested to his sister something like this:

"Sister, I trust you will not forget that Mr. Root is a married man while he and you seem to be having such a good time together."

I shall always remember her quick repartee—"Dear me! do you think I would carry on in this way with anybody who was *not* a married man!"

Her philosophy (and I think it was reasonably sound) was like this: Every man who has a wife (and especially if he has a baby too) at home, is expected to be *manly* in the best sense of the word, no matter *where* he is nor what the *circumstances* may be. "Blessed are the pure in heart, for they shall see God."

a divorce from his wife, or, rather, she was going to get the divorce—it does not matter particularly. The reason was the employment of a lady book-keeper. The wife wanted this woman dismissed. But the banker said that would mean ruin to his business to dismiss that faithful and competent woman. In discussing the matter with a Congregational minister of that town, this minister declared that this wife was unreasonable. But I said, "No, *no*, *no*! Let the banking business be ruined or even wrecked; but do not wreck or ruin the sacred relation between this man and wife." Some of you may suggest that sometimes women are unreasonably jealous. There may be a few of that kind, but I do not believe it occurs very often. I do remember one case where a man was jealous of his wife where there was not a shadow of reason for it; but this man was very soon after pronounced *hopelessly insane*.

I like to see warm and intimate friendships, and I like to see friendship between the young and old; but I always feel worried and troubled when *too intimate* friendships exist between old men and young girls. Beekeeping and poultry-keeping, greenhouses, gardening, flowers, high-pressure gardening, the study of botany, microscopy, and even astronomy, often bring together intimate relations between people in various parts of life. If some bright young woman is skillful with chickens, and you enjoy paying her frequent visits, go right ahead; but take your *wife* along, even if said wife does not care much for the chickens. If you have no wife, get one; and if this expert poultry-woman has no husband, get *her* by all means; and if you can not get her, do a good job in trying; and after you have once gotten her (so you can call her *your own*), so live that all men may know you are remembering that solemn vow you took: "What God hath joined together, let not man put asunder."

I have spoken of young girls full of health and buoyancy of spirits who oftentimes innocently attract the attention not only of old men but men of all ages. Now, when these girls need a guiding hand from the father as well as from the mother, what do you think of the wretch in human form who deliberately waylays these children (for that is what they are), and brings them down to ruin? The dear Savior contemplated this, I think, when he said, "It were better for such a man that a millstone were hung about his neck, and he were cast into the depths of the sea."

Just recently I have been pained to note by the daily papers that the city of Cleveland has been, during the past summer, inaugurating what they call "three-cent dance-halls." These dance-halls purport to be for the purpose of giving the children outdoor exercise; and I have been waiting and wondering why some of the Christian men and women of the different churches of that great city did not come out with a vehement protest, especially when the authorities are proposing to open even a greater number of three-cent dance-halls. The following clipping from the Cleveland Press would indicate that there are asylums or institutions of some kind in Cleveland to take care of these unfortunate results from the dance-halls:

"It is plainly the mother's duty to acquaint her child with the important facts of life. But the majority of mothers are obviously failing," said Mrs. Clark. "We have from twenty to thirty girls here constantly.

"They come from some of the best homes in the cities, and some of our so-called 'finest young men' are responsible. They come here almost invariably by way of the public dance hall and amusement parks.

"Just now we are caring for the results of last winter's dances in the public halls. After the first of the year those girls who this summer have frequented the parks to their own grief, will come to us. What does it all mean?

"Primarily that their mothers failed to do their duty when they failed to tell them the things they should know.

"If each girl were closely questioned I doubt if we could find three of them who had been told the truth. I base that estimate on the fact that so many of them range from thirteen to seventeen years. One child of thirteen gave birth to a baby girl here this morning. Her mother, heartbroken with grief, admitted to me that it had been her own fault.

"Since the majority of parents either can not or will not instruct their children, I think it is flatly up to the state, through the schools, to supply that instruction."

Let me add to the above clipping that I fear our reform institutions will accomplish but little in the way of cure while every great city forgets all about prevention, and keeps on opening up more three-cent dances.

When friend C. first sent me the letter at the head of this Home paper I wrote him as follows:

My good friend, I have looked over your book quite a little, but really can not take time to read all of it. It seems to be an account of neighborhood quarrels and family quarrels that nobody in the world except your immediate community is interested in. I think you did a very foolish thing in putting so much gossip in print; and if you will excuse plain talking I am sure you must be at least somewhat to blame. I never knew of a neighborhood where there were not more good people than bad, and where the general public are not always ready to give a poor man a chance. Neither in your letter nor in your book do you intimate that you have been holding fast to God's promises. I will quote just this one: "Blessed are ye when men shall revile you, and persecute you, and shall say all manner of evil against you falsely, for my sake."

Now, if you are trying to do right, and ask God to help you every day of your life, I don't see how you can have any such trouble. Get down on your knees, and ask God to forgive you

for what you have done wrong: then ask him to guide your erring footsteps. Remember also the promise: "My yoke is easy and my burden is light." "Come unto me, all ye that are weary and are heavy laden, and I will give you rest." If you will do this I am sure you will not only be at peace with your neighbors but with the good wife, the mother of your children. I wish you would show her this letter. If you are both beekeepers, I suppose you have been reading my Home talks in GLEANINGS. I have prayed for you both, and I will pray for you again.

Your old friend,

Sept. 13, 1912.

A. I. Root.

Well, in due time I received the following reply:

Mr. Root:—I am ashamed to have such a letter in my possession as you wrote me. Certainly it is plain that you did not read my book. Do you think I would place that letter in this woman's hands? She would clap her hands and screech with delight at my inability to protect myself from her. Surely she would not have to pervert that letter to her liking.

In regard to myself, first I am persecuted because I am a beekeeper; next, because I was friendly to sweet clover; then, last but not least, because opposed to strong drink being shipped into our no-license village, and kept in a blind piggery where several claimed the right to store their liquor, then come together, to drink it; then have the brewery team come from F. every few days and deliver beer in bottles and kegs at this "piggery," and also at their private houses in broad daylight. You should remember that I received 250 copies of "A Stainless Flag," by Dr. Chapman, which I faithfully distributed in F. and the towns of O. and M., and that O. came within eight votes of going dry; and I believe that, if I had had the 300 copies that the box would have held (50 copies more, in place of refuse paper), O. would have gone dry.

This (for reasons best known to myself) I left out of the book. This woman's father was a notorious drinking man. Liquor and crime go hand in hand; thus this crime comes against me. I took GLEANINGS for your writings and nothing else; yet I look it over a little, more for sweet clover and alfalfa than any thing else. I have four acres of sweet clover and 3½ acres of alfalfa. I am no hypocrite, so say little about religion. I would be a poor person to speak in church, yet I have sung in choirs for many years, and I thoroughly believe what I sing. Do you think that I could sing otherwise? This woman never looked in GLEANINGS that I knew of, nor a Bible either.

I wish I could get three or four copies of "The Truth About Sweet Clover." I think I have two or three copies of "A Stainless Flag" yet at home, which I should like to get into this jail. Oh the terror of strong drink! There is a man in this jail who killed a babe less than a day old—a Bohemian. His wife comes about twice a week to see him. He is a prosperous farmer, worth \$50,000; and now he is sober, they both nearly die over the matter.

Yours respectfully, ———.

Jail, Sept. 24, 1912.

I have given the above letter entire because it illustrates the sad condition of one who has become entangled in a family quarrel, and finally in a quarrel with neighbors also. It would look at first glance as if the writer had been persecuted for righteousness' sake; but come to look into the matter carefully it hardly seems likely that people should all be against him because he is a beekeeper or because he is friendly to sweet clover, and certainly not because he is a temperance worker and one who is faithful and earnest in distributing temperance literature. He says he took GLEANINGS for my writings and

nothing else, and yet in a former letter he speaks of having partial paralysis from turning his honey-extractor so much. If he is so much of a beekeeper as that, he certainly ought to be interested in that part of the journal devoted to bee culture. His statement that he sang in the choir for many years indicates what we already know, that those who sing in our churches do not *always* belong to the Lord Jesus

Christ; and it is also true that we have some most earnest and faithful temperance workers who devoutly hate the liquor-traffic but do not stand up before the world as followers of the Lamb of God that taketh away the sin of the world.

If any of our readers should feel like lending a helping hand to our poor persecuted brother, his full address will be furnished on application.

Poultry Department

FORECASTING THE LAYING HENS, ETC.

I have searched in forty or fifty poultry journals to see how much attention has been paid to friend Leonard's discovery that most laying hens lay their eggs a little later, more or less, every day. But little or no attention so far has been paid to the matter. That handsome journal called *Poultry* mentions a great layer that was in the habit of doing this when she was ready to take a little rest, in her wonderful stunts of an egg every day. See the following:

The best individual record is that made by Lady Showyou, White Plymouth Rock hen, No. 717. This record for each month is as follows:

November, 17 eggs; December, 22; January, 5; February, 17; March, 20; April, 29; May, 31; June, 29; July, 29; total, 208.

She has 92 days yet left in which to complete her year's record. The only month this hen has failed to lay an unusually large number of eggs was in January. We had a snow about January 5 which was nearly two feet deep, and the temperature went to about 24 below zero. Lady Showyou laid an egg the day following, and then quit business until about the 5th of February, taking just a month's lay-off. She then began a rather remarkable period of production in the days following this, laying 146 eggs in 151 consecutive days. She is the most industrious hen among the 655 in the contest. She goes immediately from the roost about daylight each day into her trap nest. She lays the egg, and is released from the nest about eight o'clock in the morning. She then spends the remainder of the day in eating a large amount of food and drinking lots of water, out of which to manufacture eggs for future days. We can usually tell about when she is going to miss a day. As this time approaches, she lays a little later each day; that is, if she is to miss soon, we do not find her in the nest as early as usual. She will go on at 10 o'clock; the next day at 1 o'clock; and the day before she misses, we do not find her on the nest until about four o'clock in the afternoon. When we find her on as late as this she then misses the following day; but the next day she has laid by 8 o'clock, and keeps it up at that hour until time to miss again. She has missed laying only five days in the past five months, and this has been true of her in each case when she missed a day.

Surely those who are trapnesting poultry at our experiment stations have had ample opportunity to learn *how many* hens lay eggs after this fashion. So far the answer seems to be that a few good layers lay in that way. Perhaps a greater number *occasionally* lay a little later each day until they finally skip a day. When

a hen is insufficiently nourished to produce an egg once in 24 hours we might naturally expect she would take a little longer period, and, as a result, finally drop an egg from the roost in the night, or wait until next morning, thus skipping a day entirely.

SURPLUS ROOSTERS; THEY ARE COSTING OUR COUNTRY 50 MILLIONS OF DOLLARS ANNUALLY.

The above is rather astonishing, is it not? But the statement comes from the State Board of Agriculture of Pennsylvania. Read the following, which I clip from one of our poultry journals:

W. Theodore Whitman, of Allentown, poultry lecturer for the State Board of Agriculture, and superintendent of the Allentown fair poultry show, in a recent issue of the *Philadelphia Press* states that he has started an earnest crusade for the production of infertile eggs for table use as a source of economy and greater healthfulness. So ardent does Mr. Whitman feel on this subject that he declares that eventually the legislature of the various States as well as Congress will enact laws on this question. Mr. Whitman declares that the fertilizing of eggs is the chief source of rots and spots, and that it is a fallacy that hens will lay better eggs if roosters are allowed to run with the flock. Roosters, he says, should be killed off, with the exception of the few best specimens that are needed for breeding, and even they should be kept penned up outside of the mating season. He said:

"It has been proved by investigations and tests at agricultural colleges that the hen does not need the rooster. She is better off without him at a time when she should be doing the work of making profit for the farmers by laying eggs which he can sell.

"If the farmers of this country would keep the hens away from the roosters at all times except during the mating season this country would be saved fully \$50,000,000 a year. By this I mean that eggs valued at this amount are spoiled every year. They could have been saved if they had been infertile."

From what experience I have had, I am satisfied that the above is correct in the main, although I should have never placed the figures so high. All that it is necessary to do to avoid this great waste is for the farmer or any other keeper to pick out his best hens and place them with his best roosters only *when he wants eggs for hatching*, meanwhile either disposing of the roosters he does not wish to breed from or pen them up by themselves. I believe it has been settled by numerous experiments

that hens, especially pullets, lay *better* when they are not worried by the males—especially the surplus males. Shall we not all of us “sit up and take notice.”

MUSTARD FOR MAKING HENS LAY; THE ORIGINAL “STRIKEBREAKER.”

So many inquiries have come to me in regard to the use of mustard, that I clip the following from the *Petaluma Weekly Poultry Journal*:

“STRIKEBREAKER” FORMULA.

For the benefit of new readers of the *Journal* we here reprint the “Strikebreaker” formula given some time ago by Mr. Keyser, and referred to by

him in his article this week. It is as follows: Blood meal, five pounds; bone meal, five pounds; yellow-mustard bran, ten pounds; saltpeter, one pound; sulphur, one pound; Venetian red, two pounds. To be fed heaping tablespoonful to twenty-five hens once a day in wet or dry mash.

Of course, the blood meal is a good thing for chickens of all ages; and so is the yellow-mustard bran; and may be saltpeter is also—I can not tell about that. Sulphur is probably a good tonic, and Venetian red, which is a salt of iron, may be all right. You will have to decide the matter yourself. As good results have come from the mixture as given above, it may be all right.

Temperance

Woe unto him that giveth his neighbor drink, that putteth thy bottle to him, and makest him drunken also.—HAB. 2:15.

Suppose I should paraphrase the above by saying, “Woe unto the United States of America if it continues to use its influence and machinery against our nation by ‘putting the bottle to the lips’ of our people, especially the boys and girls of this land.” And we might add, “Woe unto the United States of America if it persists and continues in putting the bottle to the lips of a people who have combined together to make their locality ‘dry territory.’” And still once more let me say, “Woe unto the people of the United States if they continue to put the bottle to the lips of those of foreign lands by sending shiploads of beer on the very vessel that carries less than half a dozen missionaries.” Some liquor speaker who was recently defending the liquor traffic referred to ancient Greece. He said they were the most scientific and progressive people in the world in their time; and he added that they drank wine and other liquors, and drank them freely. Somebody in the audience “turned the table” by asking the question why ancient Greece at the present time is a mass of desolate ruins instead of being the center of science, civilization, etc. Just after friend Doolittle’s protest in our issue for Oct. 1 came out, the following from the *Christian Endeavor World* appeared. Read it:

All the party platforms are silent on this vital question (except, of course, the Prohibition platform) though they deal with a great variety of topics, and enter into the elaborate discussion of all other great social and economic reforms.

The writer of this editorial has never voted the Prohibition ticket in his life, but he is growing very tired of the persistent ignoring of the saloon question by the parties of numerical preponderance. Why is it necessary to ignore other questions in order to speak out manfully on this question? All parties advocate the initiative and referendum; why should not all parties advocate a Constitutional amendment forbidding the shipment of liquor into prohibition States? It is not necessary to leave one’s

party to vote in favor of presidential primaries, for all parties favor the reform; why should it be necessary to leave one’s party in order to bring about local authority over the saloon question? Are the leaders of the great parties aware of the predicament in which they are placing the conscientious voters in their ranks? By their insistence that the saloon is not a political issue they are doing their best to make it the overshadowing political issue of the times.

Perhaps I might mention right here, what you all know, that we are finally to have a parcels post, or at least a partial parcels post, and we should be thankful for so much. How did it come about, when these politicians and a lot of our big men were strongly against it? How did it come about that the express companies finally find themselves helpless? It came about because common people like you and me waged war against the flagrant injustice of our postal laws of the past. Well, when our people and our periodicals like the *Christian Endeavor World*, with its vast following, come out openly and declare against the shipment of liquor into prohibition States, something is going to be done. For some time back I have been saying repeatedly, in substance, that I would never vote for a man or a party that is too cowardly to come out in the open and denounce the liquor-traffic. It begins to transpire that I am by no means alone in my declaration. Let me repeat, by way of emphasis, what the *Christian Endeavor World* has said—why should our great political parties, year after year, go into elaborate discussions over all other reforms, and ignore and evade this one crowning curse of our nation? A revolt is coming. I do not know but I might call it a revolution. In fact, it begins to seem as if the time were coming for another “revolutionary war.” It is not altogether the liquor-traffic. Pushing the cigarette trade where the people do not want it, in China, for instance, is in the same spirit,

"putting the bottle to our neighbors' lips."

To show you how the great wide world seems to be moving forward in the lines I have indicated, I submit below a mass of evidence gathered from periodicals scattered all over our nation:

CREATING A DEMAND FOR CIGARETTES IN CHINA.

See the following, clipped from the *Chicago Advance*:

The Anti-cigarette League and other anti-tobacco movements which have done so much to put cigarettes out of the reach of young Americans will now have a chance to work on the Chinese if they care to invade that country. Opium, for centuries the curse of the Chinese empire, has given way before the insidious American cigarette, while in America the cigarette is leading to a more general use of opium, according to Professor Albert Schneider, in charge of the United States Bureau of Chemistry at San Francisco. Following the campaign against opium in China, the "tobacco trust," through its American and European branches, sent an army of men into the empire and distributed free more than \$5,000,000 worth of cigarettes. Professor Schneider says boys and girls in China, many little more than able to walk without assistance, are confirmed cigarette "fiends." Professor Schneider said he had been told opium was put into the cigarettes now being sold in China.

Just think of it, friends! China has lately been bending every energy to banish opium, and wonderful things have been accomplished; but right in this very action, when China is struggling to get out of darkness and into the light of the present age, this huge octopus, this same "tobacco trust," proposes to spend *five millions of dollars* for cigarettes to be given away to children in order to create an appetite and enable the great tobacco company to make more money—money, just money. That is all they are living for. Shall not the whole wide world rise up in defense of the Chinese children?

SHALL WE TEACH OUR BOYS ON THE FARM HOW TO GROW TOBACCO?

Just now this question seems to be up for consideration by the agricultural periodicals of our land. Shall these periodicals publish directions for growing a crop of tobacco, without a protest or even a suggestion as to its ultimate effect? Below is a clipping from the periodical called *The Farmer's Wife*, which seems to touch the spot:

A WOMAN TOBACCO GROWER.

Commercial bulletins report a Kentucky woman disposing of a crop of 3000 to 4000 pounds of tobacco which she raised on her farm. Perhaps in dollars and cents this was a good paying crop, but we wonder if this woman has a husband who "smokes from morning till night," and whose children have inherited the taste for it until ordinary tobacco, "like father uses," does not satisfy the craving, and other strong and more harmful narcotics are resorted to, perhaps at first on the sly, but ultimately in the broad open.

Here is another clipping from that same paper:

A YANKEE QUESTION.

The alarming increase of infantile paralysis has put the whole world on its guard in the work of prevention. In some cities restrictions have been placed on the attendance of school, church, and public libraries in order to guard against the development of new cases, on the ground that 400 children have died from this disease in the United States within the last year.

Four thousand children die of alcoholic diseases in this country each year, but that business is not quarantined. It is licensed. The very powers that would guard the lives of 400 children so sacredly will sacrifice the lives of 4000 without a qualm of conscience. Why? Perhaps every reader has his own answer on this subject.

Yes, indeed, why make such an ado about 400 children, and continue to keep mum in regard to 4000 others condemned to imbecility or a crippled condition for life, etc.? Here is something worse than death in babyhood.

Here is one more clipping from that same issue of *The Farmer's Wife*:

THE CHINAMEN'S OPINION.

"Alcoholic drinks which are now being introduced into China are called by the Chinese newspapers 'new Jesus poison' or the 'German poison' to distinguish them from the English poison, opium."

To say the least, that is not the creditable reputation which the United States, posing as a missionary country to nearly every foreign land, should crave. Where and what is the power that can call a halt on federal permission to send shiploads of American merchandise, oftentimes outweighing in poison what they contain in life-uplifting principles, to foreign shores?

Poor heathen China! that is, we have have been in the habit of *calling* them that. But is it any wonder that they should strike on to that suggestive title, "the new Jesus poison"? Just think of it! Shiploads of alcoholic drinks, with now and then a missionary, to uplift and *Christianize* 400 millions of Chinese!

THE GOVERNORS OF OUR DIFFERENT STATES —SHALL THEY BE WET OR DRY?

Some of you may suggest a Governor who stands neutral. My friends, it seems to be apparent just now, even if it has not been apparent heretofore, that there is no neutral ground on the wet and dry question. "He that is not with me is against me" comes in with wonderful pertinence right here. In a recent issue of the *Union Signal* there were letters or extracts from speeches from fifteen or twenty Governors of that many States, who come out so strong and clear that there is no misunderstanding or evasion.* Here is what our good friend Ex-governor Frank Hanley has to say about it. I clip it from the *Cleveland Plain Dealer*:

"I urge you to vote for no man for governor of Ohio this fall unless he is pledged to enmity to the saloon."

Such was the gist of the message delivered by

*By the way, it is worth while to read the "honor roll" of the States that have or have had such Governors. They are as follows: Maine, Kansas, Oklahoma, West Virginia, South Dakota, Mississippi, Tennessee, Texas, North Carolina, Washington, Utah, Arkansas, and Michigan.

Ex-gov. J. Frank Hanley, of Indiana, to the Methodist ministers of the Northeast Ohio conference at their session at Epworth Memorial Church last night. A packed church auditorium and Sunday-school room listened to his address.

Why is not friend Hanley once more Governor of some of our States, or, better still, *President of the United States?*

"THE RIGHT OF WAY;" ELECTRIC CARS OR "BEER-WAGONS."

Near Cleveland, on Sunday, the 8th of September, a beer-wagon was driven leisurely up to a railway crossing. The motor-man, with two cars in charge, supposing, of course, the wagon would stop when the car was in plain sight, pushed ahead; but for some reason or other, however, the stupid driver of the beer-wagon paid no attention to the railway track nor to the fast-coming car. In an instant there was a terrible smash-up. After considerable time spent in going over the cause of the accident, the city authorities decided that the electric cars were making too fast time, especially (although they do not say so) when beer-wagons might be discommoded(?) unless a slower speed were adopted. I read the various items in regard to the catastrophe with surprise and indignation; but a day or two afterward somebody had good sense enough to send the following to the editor of our daily:

Editor Plain Dealer:—I have just read in this morning's paper of the bad accident on the Lake Shore Electric at Dover Bay yesterday, caused by a beer-wagon crossing the track in front of a limited.

I notice that the authorities of the village have concluded to cut down the speed of the cars; but there is no comment, so far as I can see, as to why the beer-wagon should be there on Sunday, in violation of the law, nor as to the driver crossing the track without looking to the right or to the left, as one man testified.

It puts me in mind of the authorities in a Tennessee town, who, when the law was passed limiting the distance of saloons from a schoolhouse, met in solemn assembly and took steps to—move the schoolhouse.

I. K. HURT.

Amen, friend H., to what you say. When beer-wagons pushing their traffic on Sunday are of more consequence than the safety of the traveling public (although to tell the truth I do not believe in so much unnecessary travel on Sunday) it seems to me things are coming to a pretty pass. Have the good people who love righteousness and hate iniquity really *all gone to sleen?*

ACCIDENTS AND CATASTROPHES IN SUNDAY TRAVEL.

In the Chicago *Advance* the editor has a column headed "I am Moved to Remark." Here is a recent one:

That an automobile can make a bloody Sunday—it would be safer for some people to be at church.

Let me add to the above that the Cleveland *Plain Dealer*, which is not at all pu-

ritanical, has repeatedly called attention to the accidents and tragedies that occur almost as regularly as Sunday comes, in greater numbers than in any other day of the week; and notwithstanding this, nobody seems to suggest that these deaths and injuries occur just as our people have less and less scruple about using God's holy Sabbath as a day of rioting and recreation.

"DUFFY'S WHISKY" FOR THE CURE OF CONSUMPTION, ETC.

The following is clipped from the *Union Signal*:

Of all the drugs that have fallen into disrepute in late years, alcoholic liquors may be said to take the lead. Whisky was once thought an essential for consumptives. Now consumptives are warned against it on every side, except by a few ignorant (or worse) doctors, such as those who give testimonials to Duffy's Impure Malt Whisky. Indeed, alcoholic liquors are now declared to be a prolific cause of consumption.

Just think of whisky for the cure of consumption, and even spending thousands of dollars for the insertion of advertisements of whisky when whisky of any sort, let alone cheap impure whisky, is the very *worst thing* for a consumptive. And yet respectable periodicals continue to accept advertisements of *Duffy's malt whisky*.

THE STATE OF MAINE AGAIN TRIUMPHANT.

We clip the following from the *Union Signal*:

TRIUMPH FOR PROHIBITION IN MAINE.

As we go to press, the news is received from our National President, Mrs. Lillian M. N. Stevens, that William T. Haines has been elected Governor of Maine. This is a splendid victory for prohibition, and a heavy blow to the liquor interests, who have been using every effort to defeat him.

As we go to press I see there is general rejoicing in temperance and Christian periodicals all over our land that Maine has finally succeeded in getting a governor who is in sympathy with prohibition, in place of his predecessor, who openly favored the liquor party.

TEMPERANCE PROGRESS IN MICHIGAN.

A goodly number of wet and dry county campaigns are in process of organization. The legislature will be in session in January. All three of the candidates for governor are dry men, and the legislature looks good. The interstate liquor-shipment bill has been favorably reported by the Senate at Washington, and is practically sure of passage.

The strongest endorsement the Anti-saloon League ever received was given it at the General Methodist Conference at Minneapolis in May, when, out of 819 delegates, only twenty-five men voted in the negative. The Detroit Methodist Conference in session at Alpena, Monday, the 16th, gave the league a most hearty and enthusiastic endorsement by a vote of 420, only three men voting in the negative.

The great question in Michigan to-day is, "Have we staying qualities?" There is no question of the final victory if we have.

GEO. W. MORROW,
State Superintendent of Anti-saloon League of Michigan.

THE COVER PICTURE.

THE scene on the cover for this issue represents a house-apiary at Vitznau, Switzerland, a little village on Lake Lucerne, at the base of the Rigi Mountain. The track in the foreground is the cog railroad leading up the side of the Rigi, the mist-shrouded heights of which appear in the background.

In Europe house-apiaries are much more common than in this country, where they are more the exception than the rule. The alighting-boards for each colony are painted different colors so that the bees, and especially the young queens, may not so easily mistake other entrances for their own.

MAKE SURE OF THE WINTER STORES.

WE have just been favored by a call from S. D. House, Camillus, N. Y., and P. G. Clark, who has been a partner of G. M. Doolittle for many years. Mr. House, as our readers know, is one of the most expert comb-honey producers in the whole country, and Mr. Clark is in the queen-rearing business with Mr. Doolittle.

Both of these beekeepers, Mr. House in particular, have noticed the lack of stores in the hives at this time of the year compared to other years, and they are fearful that the smaller beekeepers will lose a large proportion of their bees this coming winter from starvation. The trouble is that many will be deceived by looking down into the hive between the top-bars, and jump to the conclusion that there are plenty of stores because they can see sealed honey in the upper part of every comb, when in many cases there is but half an inch or so of honey, which will last the bees but a short time at the best.

Mr. House has been feeding 10 to 25 pounds of syrup per colony, in spite of the fact that there were acres of goldenrod in reach of his bees. Ordinarily, in the fall he is able to take off a super of honey gathered from fall sources and still leave the brood-chamber with ample stores for

winter; but this year he has had to do extensive feeding for the first time. The wet and cold weather prevails in many parts of the North, so that the bees could not get out to work on the fall flowers. The strictest attention should be paid, therefore, to the question of stores, for it is needless to say that no amount of packing for shelter will winter the colony without sufficient stores of good quality.

DEATH OF JOHN S. HARBISON, PIONEER BEE-KEEPER OF CALIFORNIA.

JUST as we go to press a postal card bearing the following comes to hand:

John S. Harbison, one who brought bees from Pennsylvania across the Isthmus of Panama in 1857, died in San Diego, Cal., Oct. 12, aged 86 years and 15 days. He was an honest man and a good citizen.

San Marcos, Cal., Oct. 15. G. F. MERRIAM.

While we feel sad that another veteran has gone, we can rejoice that he was permitted to live to a good old age. And, by the way, is it not true that our veteran beekeepers, especially the old standbys, the most of them, live to a good old age? I want to suggest to our good friend Dr. Miller that he take care of himself, and take particular pains to live as long as possible. And I would say the same to some others who are still "holding the fort."

Some years after Mr. Harbison took the lot of bees to California I grouped together the photographs of a good many of the prominent beemen of the world. In the very center I made a circle for the picture of Mr. Harbison; and I did every thing I could do to induce him to give me a photograph of himself; but I did not succeed, and so the picture card was sent out with Harbison's place left blank.

On my first visit to California I tried to get acquainted with him; but he was very busy, and at that time I was comparatively little known to the bee-world, and so I did not get very much in touch with him. In 1903, however, when we had a big convention in Los Angeles, he was very glad in-

deed to see me. He took me all over the country, showed me his out-apiaries, etc.

Now, I can serve our readers better by making a quotation from GLEANINGS for Oct. 1, 1903, in regard to the convention:

In taking up the part assigned me, "Reminiscences of Forty Years," I touched on the introduction of bee culture in California; and it was a happy surprise to see J. S. Harbison one of the foremost in the audience—that is, he sat near the speaker, very likely because, like myself, he is a little hard of hearing in his old age. As I finished I made a request that Bro. Harbison tell us something about the introduction of bees into California. If I am correct, this is almost the first time, if not the very first, that Mr. Harbison has attended a beekeepers' convention; and I am quite sure it is the first time he has given a full history of his remarkable venture. At first he seemed inclined to make only a few brief remarks; but in response to my repeated questioning he gave a very full and clear account of it. When he was quite a young man residing in Pennsylvania he got a notion in his head, so his neighbors said, that bees would pay well in California. He wrote there to find out about it, and was told there was nothing there for bees to live on; that if he brought them he would have to plant crops to grow honey before he could make them succeed. He could not give it up, however, and in due time he had two carloads of bees fixed to the best of his knowledge and skill for their long trip. Right and left he received nothing but criticisms and sneers. Just one man, if I remember, gave him a little encouragement by telling him to be of good cheer, for he believed that a great future was before him. He succeeded so well that only about a dozen colonies perished on the way, and then came his great triumph. It was during the gold excitement and high prices that his bees were landed; and they went off so fast at \$100 a colony that many were disappointed, and commenced bidding to the first purchasers. In this way a few colonies were sold at over \$200 each. In a little time Mr. Harbison shipped samples of his mountain-sage honey in 2-lb. sections to the principal cities of the United States. It was a novelty; and, it being war time, when things were high, his whole crop was sold at 25 cts. per lb. wholesale.

Side by side with Bro. Harbison, on the front seat, was J. G. Corey, of cold-blast-smoker fame. Bro. Corey got the bee fever; but he lived away off over the mountains, and the only way to get bees over there was to carry them on foot. He succeeded in purchasing a weak colony. As he was already something of a beekeeper he made a light hive to contain his nucleus, and strapped it across his shoulders. This hive he carried successfully more than 100 miles over the mountains. Part of the trip he had to make on snowshoes; but he got them through alive, built them up, divided, and sold his increase for something like \$40 or \$50 a colony.

Mr. Harbison was whole-souled. He not only accumulated quite a property with bees and other things, but he made good use of his means, and was foremost in all public enterprises. Above all, he was honest and upright in all his dealings. Those who ridiculed and made sport of his undertaking away back in the 50's are dead and forgotten; but the memory of Mr. Harbison's achievements will live and bless the world for years to come. May God be praised for the great and good men as well as women who have given our industry a lift and impetus in years gone by.

QUESTIONS ON WINTERING.

YEAR in and year out we are fairly bombarded with questions from beginners.

There seems to be no let-up, for there are always more beginners who are eager to learn. We are glad in all cases to answer these questions; but it is our purpose at this time to cover the ground somewhat as we have before, in order that many of our readers who, perhaps, do not realize that they are making mistakes, may be warned in time. We shall give the questions almost word for word as we receive them.

I have a room in my barn where I can easily put my ten colonies of bees during the cold winter weather. It seems to me they would be better off there than out of doors.

In a closed room above the ground, bees do not winter well, as a rule, if they are confined. It seems to be contrary to the nature of bees to be confined in a room, the temperature of which is varying from below freezing to 40 or 50, or even 60 degrees Fahrenheit. There are exceptions, of course. For instance, one beekeeper last fall asked our advice as to whether he should place his bees in an unused room in his house. We advised against the plan unless he could locate them close to the windows so they could have an entrance outdoors at all times. Before he received our letter, however, he had gone ahead and placed the hives, of which there were three or four, in this unused room, and he decided to leave them there, as they seemed to be so quiet. Last spring he wrote us that they wintered well. We should say that they wintered *in spite* of being placed in this room, and we feel sure that they would have been better off in a cellar or well packed out of doors.

There are several inches of honey in the upper part of the central combs in one of my hives, and rather more in the outside combs. Is this enough?

It all depends upon the size of the colony, and also as to how much you mean by "several inches" and "rather more." A medium-strong colony should have not less than 30 pounds of sealed stores. But you probably do not know how much comb space this amount would take. A comb of Langstroth size, which is the size of the regular Hoffman frame, if full of honey will weigh anywhere from seven to ten pounds. You can tell something from this about how much comb area should be filled. If a colony is being wintered on eight combs we should say that there should be three or four inches of honey in the upper part of the four central combs, four to five inches in the next comb on each side, and five to six inches in the outside comb on each side.

My bees have enough to last them through the coldest part of the weather, and then I expect to feed again in the spring. How shall I make the syrup for spring feeding?

It depends on circumstances again; but

equal parts of sugar and water will not be far out of the way, although two parts of water to one of sugar would be better.

We feel sure your colonies would be in far better condition if your hives contained all the stores they needed until the new honey comes in next season. If you have a reserve set of combs of sealed stores, it is all right to use them where they are needed in the spring; but spring feeding of syrup, especially by an amateur, is liable to make trouble. The bees get excited and are likely to start robbing. Most of the best producers have decided that their colonies, taking every thing into consideration, are in the very best possible condition for the next honey-flow if the combs contain sufficient stores in the fall, so that the bees in the spring need not feel that they must economize.

I live just ten miles north of the Ohio River, and my colonies are in single-walled hives. Will it be necessary for me to pack them out of doors, or winter them in a cellar?

We would not advise cellar wintering in your locality, for you have a good many warm days, especially in an open winter, when the bees can fly; and on these days bees in a cellar are likely to become restless, for it is hard to keep the cellar temperature from rising too much.

As to whether you will need to pack them out of doors, this will depend on the winter. Last winter colonies in single-walled hives even quite a distance south of the Ohio River suffered, and many, of course, died outright. In general, we may say that strong colonies in single-walled hives south of the Ohio River do not need very much extra packing, provided a sheltered location can be secured. By a "sheltered location" we mean one protected from the prevailing cold winds in the winter. If these winds come from the west, a location on the eastern slope of a hill is usually quite sheltered, or on the east side of a woods. A high board fence is a great help; but for best results it should entirely surround the apiary, as a fence merely on the west side sometimes causes counter-currents that really do as much damage as the unbroken wind.

For those who are undecided as to what to do in regard to packing, we may say that, during a cold snap, when the temperature goes lower than usual, colonies may be picked up temporarily and placed in the cellar. This applies also to localities further north, even to colonies in double-walled hives in case they stand in an exposed location. As has been mentioned so often, bees will stand a great amount of cold if protected from the wind. The

temperature may be quite low in a sheltered location without serious damage.

Three of my colonies are queenless. Will they live until spring?

Probably not. If you have any other colonies in your yard that are weak, but that are accompanied by a fair queen, unite the queenless colonies with them. As late as this it usually does not pay to buy queens, even if you can get them; for there is more difficulty in getting them introduced; and if the venture is unsuccessful the queen is lost and the bees too. It is better to unite them than to run the risk of buying a new queen.

The time to requeen is in the latter part of August or the first of September. The young newly introduced queens, especially if the colonies are fed to stimulate brood-rearing, will get a fine lot of brood started, which will result in strong vigorous young bees by the time the cold weather comes on, and there is little danger then that the queens will be missing during the winter or spring, just when they are needed the most. If all beekeepers would look carefully to this matter of queens in the late summer or early fall there would not be the great rush for queens in May and early June as there always is—at a time, too, when queens are much more expensive than they are later in the season.

I have one colony—a late swarm—that covers only four combs. Is it too weak to winter, or shall I unite it with another colony?

If it covered four combs on a cold day it may be strong enough to winter; but on a warm day the cluster should expand to six or seven combs. It depends on the temperature when you make the examination.

Right in this connection we should like to say a word regarding some beekeepers who seem to have phenomenal success in wintering. Some, even in cold climates, winter year after year with scarcely the loss of a colony; and others in a similar location, or in one that is even better adapted for wintering, perhaps, lose a large proportion. This loss may be explained in some cases by poor winter stores; for instance, aster honey, in localities where there are few flight days, is sometimes unsuitable. But we are inclined to believe that the difference is more often because of a difference in the strength of the colonies. Good strong colonies of vigorous stock made up largely of young bees, with plenty of good stores, will winter in spite of almost every thing, and the hives will be fairly boiling over with bees in the spring. Such colonies do not have to be fussed with and nursed in order to be in good condition for the honey-flow, and spring dwindling is unknown.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

RICHARDSON'S hive-stands, p. 664, look good. Bottom-boards will not rot as they will on wood, and hives will not tumble off as they will on stakes.

THE *British Bee Journal*, p. 307, says, "The average profit per hive from properly managed British bees is 20s." That's about \$5.00—better than we can do on this side.

E. S. HUDSON gets comb honey built between brood-combs, p. 638. That's all right if the brood-combs are new; but next to old black combs I've had honey sealed very dark.

C. M. HICKS, you say, p. 635, that bee-way sections without separators are harder to handle than plain ones. Please play fair. Were the plain sections also without separators or fences?

LOUIS SCHOLL, you say, p. 652, that you advertise "as exclusive comb-honey producers" when you sell honey that is one-third extracted. What would you advertise if you produced no extracted?

P. C. CHADWICK, p. 616, even if bees do prefer small entrances, does that prove that small entrances are best for you? Do they not swarm more with small entrances? [Small entrances in summer don't work well here.—Ed.]

YOUR SURMISE, Mr. Editor, p. 646, is that the queen, when crowded, drops eggs promiscuously, and the workers put them in the cells. My guess is that the queen herself lays in cells already occupied. I wish we could know for certain.

C. H. HARLAN, radiator-pipes make your cellar too warm for the bees, p. 638. Ever try wrapping two or three thicknesses of asbestos paper around the pipes? [Such protection will answer on furnace pipes, but not on steam or hot-water pipes.—Ed.]

MENTION is made in the last Straw, p. 649, of a "package of bees without brood or bees." If that is the work of "the intelligent compositor" he should be discharged instant. If it was in the manuscript—well—er—any one is liable to make mistakes.

J. WARREN ARTHUR, you like side starters in sections better than full sheets of foundation, p. 638. But don't the bees build drone comb in your sections? And doesn't that injure the looks of the sections? And, unless you use excluders, don't queens lay in that drone comb?

LEWIS P. TANTON'S story, page 581, sets one to thinking. In some cases such as he mentions, the disappointing delay is worse than if the amount of money involved had been stolen outright. If it's right to give the name of a common thief, why isn't it right to give the name of one who is worse than a common thief?

A FRENCH physician, Dr. Carton, has written a brochure in which he denounces as the three most deadly aliments, alcohol, meat, and sugar.—*L'Apiculture*, 272. And I suppose eating sugar does more harm in this country than in France, since more sugar is eaten here. [The world is full of extremists, and Dr. Carton appears to be no exception. We never knew of a husband and father who, after buying meat or sugar, abused his family or deprived them of support.—Ed.]

G. M. DOOLITTLE, you say, page 508, "There is no prettier sight than a super of sections all alike in advancement, with not a cell yet sealed." Isn't that same superful prettier after the sections are all sealed snowy white? Yet I'm like you; that super of unsealed sections, every section just alike, thrills me with delight as does no lot of finished sections. I suppose it's because of the evidence of the strong force of bees at work, and the flood of honey that a good God is giving us.

SOME THINGS P. C. Chadwick says, p. 651, suggest that bee-inspectors might be worth their keep if for nothing else than to spread information among beekeepers that will hardly be reached in any other way—I mean aside from foul brood. [It is certainly true that bee inspectors do a great deal of good aside from the service they render in the elimination of bee disease. Many do not read any books or papers, and yet they are always glad to get advice by word of mouth. The helpful advice given by the bee inspectors is worth all it costs to send them around, even if no service were rendered in combating bee disease.—Ed.]

H. H. ROOT, you say, p. 90, that "bees do scarcely any work in a comb-honey super three stories high." I wonder if that means just what it says. At this present moment half my colonies with section-supers are working in supers three or more stories high, and they were higher a week or two ago. [In this particular I was taking Mr. Anthony's statement, and possibly I put the matter a little too strong.]

But I should like to know just how many comb-honey producers stack up their supers three high. If the season were not exceptionally good it would seem as though there would be danger of too many unfinished sections.—H. H. R.]

"WE INTEND to preach the doctrine of producing more comb," etc., p. 610. I've an idea that a strong factor in the preponderance of extracted over comb was your preaching "more extracted." Look out now that your preaching doesn't get too much comb on the market. I'm leaning just a little to the opinion that it would be for the general good if only extracted were produced. [Where did we continue to preach more extracted, as we are now advocating more comb-honey production? —Ed.]

MR. EDITOR, can you tell us whether sections will ship as safely in safety shipping-cases without carriers as they will in regular shipping-cases with carriers? If so, then the safeties are the cheaper. Let's figure. Suppose we have standard sections and buy cases by the hundred.

Eight 24-lb. regulars will cost	\$1.44
Carrier for same.....	.60
Total.....	2.04
Eight 24-lb. safeties will cost..	2.00

A saving of half a cent on each case by buying the safeties. Suppose we use 12-lb. cases.

Twelve 12-lb. regulars will cost..	\$1.38
Carrier for same.....	.60
Total.....	1.98
Twelve 12-lb. safeties will cost..	1.80

A saving of 1½ cents on each case by buying the safeties. And that counts nothing for the labor of putting together the carriers. On the other hand, it must take a good deal of time to put the sections in the cartons of the safeties. With the carriers you must always ship a multiple of 8 or 12 cases. With the safeties you can ship any number you like. I think I would rather handle single cases at a time than to handle the carriers. One man or boy can handle the single cases, and there must be two men to handle the carriers. But the question still remains: Are the safeties as safe without carriers as the regulars with carriers? [No comparative tests of the two kinds of cases in the manner stated have been made; but we would recommend both safety cases and carriers combined. While the safeties compared to the old-style cases are unquestionably superior to the old-style cases when neither is in carriers, yet we believe it is very wise to give comb honey all the protection it can reasonably have. Of one

thing we are sure—that, unless the old-style cases are discontinued, the comb-honey business is doomed; for commission men and buyers will not longer tolerate the breakages of the combs, the consequent leakage, and the difficulty of making settlement satisfactory to either party.—Ed.]

J. F. CRANE, p. 577, just to please you and J. L. Byer (and myself) I'm going to say "grade" instead of "hybrid" hereafter. [Apparently the term "hybrid" has been undergoing a change, or else the term is broader than it is usually given credit for being. The latest edition of Webster's New International Dictionary gives it the following definition: "The offspring of a male of one race, *variety*, species, or genus, with the female of another" (italics ours); "a cross-bred animal or plant . . . Those between distinct species are distinguished by some as *true hybrids*. . . By many plant and animal breeds *hybrid* is now limited to a cross between different species, cross-breed being used for a cross between races or varieties of the same species." Now the last sentence above quoted narrows down the term; but nevertheless, according to the dictionary it is perfectly correct to speak of a hybrid as a cross between varieties. The Century Dictionary and Encyclopedia have the following: "The offspring or progeny of animals or plants of different varieties, species, or genera; a half-breed or cross-breed . . . The *commonest* are those resulting from the union of opposite sexes of *varieties* of the same species. . . Hybrids or half-breeds of the human race are among the best known examples." The italics in the foregoing are ours.

It will be seen from the above that the two dictionaries very closely agree in sanctioning the broader use of the term. Therefore it does not seem to us that "hybrids," denoting a cross between Italians and black bees, for instance, is incorrectly used. It is possible that the word has degenerated; but if so, beekeepers are not the only ones who have had a hand in thus changing the meaning. Moreover, assuming for the moment that the narrower meaning is the correct one, the mere fact that beekeepers dropped the term "hybrid" would have no effect on the use of the word in general.

In GLEANINGS and in the ABC and XYZ of Bee Culture we stand as opposed to changing apiarian terms which have been long in use, unless such terms are clearly misleading. For example, we favored dropping the term "black brood," owing to the fact that the diseased brood in this case is not necessarily black.—Ed.]

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

Speaking of queen bees, may I be allowed to forecast that, in the near future, there will be some radical changes made in the methods of raising them? Lately we hear much about rearing from eggs instead of transferring the larvæ, and I believe this is one step toward the change that is apt to take place. Anyway, I am very firmly convinced, after an exhaustive test, that queens reared by transferring the larvæ do not live nearly as long as do those reared under the swarming impulse. I base my belief on a large number of cases taken collectively, not on individual cases, which prove nothing one way or the other.

* * *

Relative to the new postal ruling of the United States regarding the mailing of queens, in our humble opinion the Department is to be congratulated on making an effort to prevent the dissemination of disease in mailing-cages, and I wish that our Canadian Postal Department would make a similar ruling. At the last Ontario convention held in Toronto, November last, this matter was spoken of when the committee was considering what recommendations to make to the Federal Parliament regarding necessary legislation for the bee industry. While the most of the members of the committee, including myself, were not in favor of doing any thing to hamper the free introduction of queens into Canada from the United States, owing to the fact that the demand for queens is greater than Canadian breeders can supply, yet I venture to say that every member of that committee will be glad that the ruling referred to has been made. While the chances of introducing disease in mailing-cages may not be very great, yet that there is a chance no one will dispute; and then, again, there is no question but that some queen-breeders have been unjustly accused in the past. If they take all precautions against the chance of disease being carried in their cages, there will be no chance of an unjust accusation being made against the queen-breeder.

* * *

From the fact that some queen-breeders have made a success of using a candy with no honey in it, it does look indeed possible in the near future for *all* of them to be on the safe side regarding any accusation of spreading foul brood through the country in their mailing-cages. While not in the business, most assuredly I would try the plan if needing any candy for fitting up

mailing-cages for queens. In England it is quite a common thing for many colonies to be wintered exclusively on candy instead of honey stores; and in this country it has been tried to a limited extent as well. Only a few days ago, while talking with Mr. F. L. Pollock, of Stouffville, Ont., he told me that last winter he tried the plan with the best of success, and that he considered it more economical than feeding sugar syrup, and not nearly so much bother. This winter I believe he intends to try the plan on a more extensive scale, and results will be awaited with interest. I believe he follows the plan for making the candy as outlined in GLEANINGS. I said *he*, but really it should be *she*, as Mrs. Pollock does the work of making the candy: just as I expect another woman would be asked to do the work if I needed some candy made. It's a sure guess that I would burn it if I tried to make it myself.

* * *

ITALIANS CAME OUT AHEAD IN THE RACE.

In Eastern Ontario the majority of the bees have been of the old-time black or German variety; and while my limited experience in that locality as an inspector convinced me that those bees in their purity are much more quiet than many of the hybrids kept further west, yet I knew nothing positive as to their honey-gathering qualities as compared with the Italians or Carniolans. In the spring of 1911 I bought a large apiary out there, and in the fall about a third were Italianized. This season (a poor one in that section) the 80 Italians stored more than double as much as the 160 blacks in the same apiary, all receiving the same attention. At the last convention of the Ontario Association, some men from the East strongly championed the blacks; and I have been seriously wondering lately whether they have ever given the other races a trial. At any rate, if all that east yard of mine had been requeneed a year ago it would have meant more dollars for us this year; and when a man tells me after this that the blacks are as good as Italians or Carniolans I will just think he is joking. At any rate, European foul brood is causing a good many to change stocks, for while Italians and Carniolans are not *immune* to the disease they stand up against it much better than the blacks. In fact, experience has shown that there is no use trying to cure the latter race if they once get infected.

Beekeeping Among the Rockies

WESLEY FOSTER, Boulder, Colo.

Economy in beekeeping is a rare thing to find. We lose here in the West by not making use of the wax, and also the honey suitable for vinegar. Some of us are buying covers and bottom-boards that could be made as well, and for half the cost, at the home planing-mill. I would not advocate any thing but a dovetailed hive body for the West; but it is a fact that many beemen are obtaining very satisfactory service from home-made fixtures. The making at home of super bodies, and purchasing only the inside furniture, means a saving of money for many where freight rates are excessive. The manufacture of brood foundation from home-rendered wax is successfully done by an increasing number of apiarists during the winter months. Surplus foundation, as yet, seems to be beyond the ability of the average beeman.

I have galvanized-iron covers that are the equal of factory-made covers costing 50 cents each, that cost me 22 cents—11 cents for the galvanized iron cut and crimped, and 11 cents for the wood sawed and ready to be nailed together. However, it is not advisable to go into home-hive construction until the comparative costs have been ascertained. I would not attempt, located as I am, to make my own frames, section-holders, separators, hive bodies, nor shipping cases. Some may be located where it is necessary to make these things or have them made in their home town.

* * *

BAITS AND BULK COMB HONEY IN COLORADO.

In talking with Mr. A. S. Parsons, of Rocky Ford, the other day, he told me that the complaints of the buyers of bulk comb honey might be partly attributable to the fact that in selling the honey the chunks (should I say bulks, Mr. Scholl?) were taken out and sold, without a sufficient amount of extracted taken out with each sale. The combs keep rising to the top; and when the honey is two-thirds gone from the package, there is nothing left but extracted honey, which makes the dealer come to the conclusion that he has been cheated.

The beemen at Rocky Ford sell all of their bait combs that contain sufficient honey as bulk comb honey, breaking the combs from the sections and packing them in large-mouth sixty-pound cans. Extracted honey, warmed just enough so that it will not melt the combs, is poured over them until the can is filled. A sixty-pound can will hold about 58 pounds net, and they bring from \$5.50 to \$6.50 a can. There

seems to be a good demand for all of this kind of honey the producers have; but of course the amount they have is limited. Kansas takes the most of it, the local market taking none whatever, or practically none.

* * *

GO WEST, YOUNG MAN, GO WEST.

S. King Clover writes that one should think twice before leaving cozy homes in the East, where society is established on a more or less firm basis, for the undeveloped regions of the West. This is sound wisdom; and one who has a well-established business in the East would be foolish to pull up and move into a country where conditions of life are so different. But the West still holds opportunities for the young man whose habits of life have not been firmly formed, and who can adapt his practice to new conditions such as the West presents. This is a young man's country, and the obstacles to be overcome are no more difficult than the pioneers of the middle West had to conquer. The young man who can enter a new country, clear the sage brush, dig ditches, build roads, and put irrigating water on his land, is building a rugged worthy character at the same time. He will outdistance the young man who inherits an improved farm in the East, for which his father had to work and struggle. Because the West is hard to win to civilization and tillage is why the people here think so well of their country. It is said in Oregon that, the further West one goes, the more the people boost their country. I thought that Colorado people boosted things to the limit. What we need is more builders and fewer boosters. The booster is the speculator who buys land at \$10.00 and sells it for \$50.00 or \$100.00, while the builder is the one who puts in a crop of potatoes and sells \$100.00 worth to the acre or better.

There are still opportunities in the West for beekeepers; and one contemplating moving would do well to take an extended trip, looking up a desirable location. Places can be found where crops of honey will be good, and where it will be a long time before there will be any danger of overstocking. The part of the West with which I am familiar is distinctive in two ways—the delightful climate and the progressive mental atmosphere that conquer obstacles. The West needs young men, and many of them. Riches may not be found, but a worthy life may be led in the fertile valleys of the Rocky Mountain region.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

Letters of inquiry regarding the State Association should not be sent to *me*. Write direct to Sec'y A. B. Shaffner, 4232 West First St., Los Angeles, Cal.; and while you are writing you should send in \$1.50 dues for a year, and get the crop reports next season. They will be worth many times more than the price of your dues.

* * *

October started in with good general rains, the value of which will depend on how soon others follow to sustain the vegetation that has started. Fillaree is coming up nicely, and if occasional rains continue, our early aid to spring breeding would be assured. Personally I have no misgiving in this matter, and am willing to go on record as believing we are to have plenty of rain, a warm winter, and a honey crop.

* * *

I have been harping about extracted honey since I began the editing of this department, and have run the department with my own ideas and policies. My views have been the opposite of the editor's in this respect, because of an honest difference of opinion. But the price of the best grade of comb honey this season in Los Angeles has averaged ten cents a pound higher than the best grade of extracted. Here we have a difference in price that surely must look good to beekeepers who are figuring on how they can get the most from their bees. A beekeeper told me a few years ago that he put just as little into his bees and got just as much out as possible. That kind of beekeeper has, to be sure, no business working for comb honey; but the majority are of this class, and find it easier to turn an extractor than to scrape and pack sections. It begins to look to me very much as though there were going to be some good money in comb honey for those who are willing, and fitted in knowledge and patience to give it the proper attention. The past season, one of the most successful beekeepers, to my knowledge, produced largely comb honey, using extracting combs for the lighter flows. His best grade sold for 18 cts. per lb., while the best extracted brought only 7 or 8 cts. Such a difference will make comb-honey worth while.

* * *

I mentioned, Oct. 15, something about California beekeepers being a demoralized set so far as being organized or alive to their interests is concerned. I am going to continue on this subject for two reasons.

First, I want to say there are very few industries in the State, of as much im-

portance as the bee industry, that are not better organized. The orange, raisin, and celery growers and other producers have their organizations through which they work in unison, and trust those in charge of the organization. I believe the success of many of these organizations is due to the fact that they have many men in them who are not strictly of the granger class. We beekeepers, to a very great extent, are purely of granger tendencies, and inherit a suspicious, distrustful, independent nature that is hard to overcome. We are not to be blamed in the least for this attitude, for we have long been the prey of buyers and commission men, and our misgivings are well founded; but this is more reason why we should be in a mutual organization composed only of producers, for then we should be able to help protect ourselves. A great many look upon organization as did the Jew who was going to Europe with his son. When in mid-ocean their ship sprang a leak and was slowly sinking. The son, learning of the danger, rushed to his father, exclaiming, "Father, the ship is sinking." The father answered, coolly, "Vel, vot of it? It don't belong to us."

This illustrates my point—that it is hard to get beekeepers to realize that their industry is sinking. It may not belong to them, yet they may go down with the rest. I am becoming more of an enthusiast over organization every day; but I believe it will be necessary to educate to some extent before we can succeed in getting a great many to take hold. But this is being done, especially the last few months, during which time the State has aided our association in holding meetings at various points which I have previously mentioned.

Second, the average beekeeper is not posted on markets or prices, and many in the more remote districts sell their honey to the first buyer who comes along, at whatever price is offered. Naturally he feels that it is *his* business, and it undoubtedly is; but in many cases honey prices are from one-half to two cents more per pound than the grower gets, and, in consequence, he takes from 60 cts. to \$2.40 per case less than he should. As soon as we are able to get our membership up to a point where we can furnish cans and cases at a reduction to our members, then they will begin to come in out of the hills to join our association.

Five cents saved per case looks larger to many beekeepers than one-half cent more per pound in the price of their honey.

Conversations with Doolittle

At Borodino, New York

DISPOSING OF A HONEY CROP; THE COMMISSION MERCHANT NOT TO BE DESPISED.

"I want you to tell something about disposing of a crop of comb honey to the best advantage."

"The first thing is, to put it up nicely for market, so that it will attract the eye of every person who happens to see it. Years ago I used furniture tacks, with large shining metal heads, using one over the head of every nail that was in sight on each case containing the honey. Then I used a dark wood, a sort of yellow brown, with lighter shades all through, showing the 'grain' of each year's growth. The name of this wood is sumac. This was for the side cleats, which held the sections in the cases, these cleats being only 3-16 inch thick, 1½ inches wide, which allowed two-thirds of the 'face side' of the sections to show their nice white faces to the public. To say that I enjoyed getting out the sumac poles, which grew on father's land, sawing, planing, and preparing them in my own shop on winter days, hardly explains the fun I had in fixing up these fancy cases. Cases thus fixed up, filled with the nicest snow-white combs of basswood honey, were admired by hundreds at my home. I sold much of it at home, and what was not so disposed of I sold with the remainder of my crop to a dealer in Syracuse. A case of this was set outside his store near the walk, and he told me that almost every one who passed by was sure to stop and look at it, making many exclamations regarding its beauty, and then would come in to purchase some.

"But having the crop all put up nicely, what next? No matter how good one may feel over a crop of the most attractive honey, he must have no thought of holding this crop permanently. One can not live on honey alone, and he must exchange this beautiful crop, in which he has taken so much delight, for money to buy the things another has produced.

"I remember, as yesterday, when my father, more than half a century ago, exchanged all the box honey he could produce (and he had nearly three-fourths of a ton one year) for boots, shoes, stockings, clothing, furniture, etc., doing this to as good advantage as would be the case if we received 40 cents a pound to-day.

"The disposing of one's crop of honey seems to be the one thing which puzzles the beekeeper—not that it is difficult to

sell it, but to sell it advantageously; that is where the trouble comes in. Beekeeping is an *industrial* pursuit, while the disposing of the product is purely commercial. Few men are born equipped for a commercial life; and where they are, if they should start out with an industrial pursuit they would soon work out of this into the commercial, where they rightfully belong. Not one man in five thousand is equally fitted for both the industrial and the commercial. I know that farmers sell their own products quite generally; but their hogs, sheep, cattle, butter, cabbage, grain, etc., are things which are *sought* after by dealers in every city and at every railroad station throughout the country. But it seems to be different with honey, especially in this day and age of the world. Fifty years ago, occasionally a dealer would go through these parts buying up what honey he could; but this method now would be a surprise. Honey does not seek its level in the markets as do flour, meat, sugar, etc., and it does not have a standard quotation as do these things. It is not uncommon to find the price quoted in one market from twenty to thirty per cent higher than in another city, when it would seem by the scarcity of nectar-secreting flowers that the latter should be the one that would pay the higher per cent.

"In view of these disadvantages which the apiarist labors under, and after trying most of the many plans given for the disposing of a good crop of honey, after it is nicely put up, I have come to regard the commission merchant as the best friend of the one who does not care to try his hand in a commercial way. By devoting oneself to the specialty of beekeeping, the bees may be made to give greater crops, and thus one may, to a certain extent, save the commission charged for the selling of his product. There are many commission merchants who are as upright as they of our own household; and by using the proper care one can find such as are proved to be reliable by a reputation founded on a long-established business. Having found the righteous man (Dun's or Bradstreet's commercial reports will help in this matter), then one should get his product into their hands so they can have sufficient time to take advantage of the market in selling it. I find that the best time to have it reach these merchants is from September 20 to October 15, in order to give them a chance to obtain the best price."

General Correspondence

MOVING 30 COLONIES OF BEES 40 MILES

Some Predicaments Resulting from Inexperience

BY "SUBSCRIBER."

For several years Bert Harper and I kept bees in a little town where we attended high school. As I lived at one end of the town and he at the other, neither of us feared overstocking the location, for our combined apiaries did not amount to over seventy colonies. During the school year we were busy with our studies; but our spare hours we freely gave to the bees. This was only fair play, for they were very busy for us. But when we came to the end of the senior year we had to part company, and this is the reason for the story.

That spring Bert's father sold his farm and moved away to another, which was some forty miles distant. The purchaser of the old farm gave consent to Bert to leave his thirty colonies of bees on the place till the end of the school year in June, when he planned to move them to their new quarters. About the end of July, Bert paid me an unexpected visit, and asked if I would help him move the bees the next day, in case he had every thing ready beforehand. I told him I would do it if he couldn't get any one else, but that it would be a dangerous job; for if I knew anything about bees, they were a bad cargo. It would be hard to close the hives bee-tight, and yet give sufficient ventilation. The least error would mean escaping bees, stung horses, a possible runaway, a smash-up, and broken necks. When he heard all this he insisted on my helping him, for everybody else was afraid to venture. So, not to go back on old friendship. I promised to be ready the next day.

Late the next afternoon, as the shadows began to steal across the fields, and the sun was putting himself to bed, we started to nail up the hives and fit them for the long journey. Some of them were shaky, and the work consumed time. By eight o'clock this part of the work was done, and the next thing was to load up. Bert had an idea that this could be done in a few minutes, but he was sadly mistaken. The hives gave us no end of trouble. Nothing seemed to fit on the rigging of the wagon. The main trouble was that, besides the thirty hives, Bert was taking what was about a wagonload besides, comprising canned fruit, house-plants, empty hives, and a lot else. It was well on to

eleven when we got the load in shape and tied the last rope.

"You're sure it's safe, are you?" inquired Bert, looking carefully at the high-piled load.

"Safe!" said I; "of course it isn't very safe; but it's the best anybody can make it."

Then we started the horses and the trip began. When we hit the main road, affairs moved more smoothly and rapidly. It was now close to midnight, the road was very dark, and in some places more narrow than we liked. Our lantern, too, was a bother, for it would flutter every little while and go out, and it took about ten minutes every time to get it going again. Still, we were quite happy, for the worst seemed over. The world was still, and all we could hear was the steady hum of the bees and the straining and banging of the great wagon.

After about half an hour we came to Rock Gorge. We got down the one side safely, and the ascent commenced on the other side. All went well till we were almost at the summit, when one of the hives fell off with a bang in the road behind. I yelled to Bert to drive right on to the top, while I saved what was left of the hive. It was a sorry mess; but I fixed it up the best I could, and off we went after a delay of half an hour.

"Bert," said I, "you will have to drive some if you get there; it's almost twelve now, and we have come only a few miles."

"It can't be helped. We ought to have loaded up better," was Bert's somewhat tart response.

We had not covered many miles before I became curious about a hive on the edge of the load; and as I leaned back to make it fast I lost my balance and went head first into the road, taking the hive with me. For an instant I was dazed as much as the bees may have been; but in due time we all responded to the call of duty. I got the hive back on the load, picked up the lantern, climbed up on the rig, and once more we started on our way.

After a while we saw the lights of Williamsburg shining through the night, and we rejoiced that our first twelve miles would soon be passed. We wished we were on the other side, for the hill leading down to the village is steep in places, and right at the foot of the steepest place there is a railway track.

The hill and the railroad together made a bad combination on a dark night. We had just come to this place, when all at

once there was a sharp crack, and the horses snorted and jumped in alarm. I called to Bert, "Into the ditch! quick! The chain is broken. Get into the ditch or the load is lost!"

Bert managed to make the ditch, and the load was saved for the present. Bert climbed down, discouraged.

"This is a fine fix," said he. "The chain is broken, and not a soul around here that I know. I wish I had never started."

I was not feeling so bad, and hunted up some fence wire with which we fixed up the chain, and on we went with renewed courage. Our course led straight through the town; and once when we were well through it, we took the State Road direct for the upper country, and toward Galen Hill. The load seemed to be charmed—every thing was going nicely, and the horses stepped along as they had not done at all before. As we reached the foot of the rise the sun was just peeping up above the eastern hills. We thought a rest would be a good thing, and so we halted and inspected the load. It was a sorry sight. It looked just as if some one had taken a stick and stirred the whole load of hives and truck into a tangled mess.

But the worst of our evils just began to manifest itself; for with the broad daylight, every once in a while a bee would escape and flit in an uncertain way about the wagon. The higher the sun rose, the more the bees got out, till we were really at our wit's end to know what to do. If we stayed there in the road we would block up the traffic, and that would not do. If we went ahead we were sure to be in trouble; for with twenty miles to go, and thirty colonies of angry bees to manage, we had our hands full.

But standing still was not going to help, so I said, "Come on, Bert. I don't believe we can get very far with such a load; but we can try, and may be the bees will not bother very much." So the horses were hitched on again, our bee smudges were lighted, and the war commenced.

Galen Hill is about three miles long, but not very steep. We made the ascent slowly, one driving and the other sending great clouds of smoke on the bees. By the time we reached the top, the bees were under control and our prospects looked brighter. Bert and I both thought that our difficulties had been surmounted as we triumphantly drove through Galen.

The village passed, the level road lay before us. Suddenly, without any warning, something struck me a sharp blow on the face and I felt a burning prick. At

the same moment Bert ducked and fought the air. "Where did that bee come from?" I yelled. "They're getting out. Smoke 'em! smoke 'em! Can't you?"

Just then another vicious insect got me on the hand, and then another and another. A thin stream of yellow bees was leaking from the hives. Bert snatched up the smoker and began to do his best, but all too late. One of the horses jumped and plunged sidewise. Instantly I dropped on the whiffletree and pulled the bolt, with not a second to spare, for the horses leaped and would have bolted, but Bert grabbed one by the head and the other, and so we got them away from the wagon. They were almost crazy with the stings, but Bert brushed some of the creatures away from their ears, and they became less restive. Little by little we gained on the bees, till the horses recovered their senses. When all was quiet we stabled them in a neighboring barn and turned our attention to the bees.

The wagon was where we had left it, in the middle of the road, and the bees flying all about it. The air seemed full of them. As we came up, how they did sting! I saw the load was blocking the highway, and so by pulling and pushing we got it off to one side of the track and made an examination. It was not one hive that was leaking, but all of them in general. The worst was that we could not find any holes from which the bees were coming, and yet they were coming. The case looked hopeless. Just then a team came in sight. Here was a new danger. Would it be possible for that team to get past the raging bees? In a few minutes the vehicle was right abreast of us, when the horses made one plunge, almost throwing the driver from his seat, and disappeared down the road in a cloud of dust. A few minutes passed, and another came and had the same experience. To help out we opened the fence on one side of the road to let teams pass by through the field; but this expedient did not relieve us entirely, for some would stay in the road in spite of our warnings.

It was about noon when a man came along, driving a spirited team, and tried to get by our wagon. The bees went after him. His horses shied, and then almost balked. He was almost by when there was a crack, and his whiffletree was down and also the wagon-tongue. This was a bad job. In a second we both jumped to help. I picked up the wagon-tongue, and Bert hung on to the whiffletree while the man urged the horses forward. The lady

in the carriage screamed, and jumped up and down with fear. This scared the horses worse; and when she pranced they did too. But the man soon put a stop to this; and as we were all the time getting further from the hives, the bees went back to their company, and our friends drove off.

The automobiles with covered tops got it worse than the carriages. The first one came along just after dinner, at full speed. No heed was given to our warning. As the party drove by, the hood scooped up a fine mess of bees, and there were yells and hoots and plenty of language. As the afternoon wore on, the time seemed interminable. We had been up all night, and were sleepy; but there was no sleep for us, for teams kept coming and going, and it was our duty to warn them the best we could.

When the welcome night fell at last we began to rearrange the load; and after a bit we had things fixed for the seventeen miles that were still before us. By nine o'clock that evening we were again moving. The horses pushed on in the darkness, along deep forest roads, and past cultivated fields. All the time we were so sleepy that we could scarcely hold our heads up. By ten I was so completely worn out that I dared not hold the lantern for fear of dropping it, and tied it to the top of the rigging, still keeping my hand on it. The next thing I knew, Bert was punching me for I had let go of the lantern. The road was far from safe, for on one side was a high cliff, and on the other a deep gorge. If the horses swerved, an accident would be sure to follow. But though we were almost dead from lack of sleep, it was imperative to get on. We must reach our destination before morning, for a second day like the first in the road would kill the bees. So we pushed on, one walking while the other drove, and then the other did the same.

We had been going this way about an hour, when all at once Bert called out that he had missed the crossroad that led to his place. With some impatience I advised him to hunt it up, so we could go ahead like sane people. Off he went with the lantern, and presently returned with the word that he had discovered it. At once the horses were turned about and headed in the proper direction. It did not take long to get to the crossroad, and we were nearing home, with the farm buildings only a mile away. We felt the joy of victory. But this was not for long. In the uncertain light of the morning,

when we came to a small bridge we failed to keep to the center, and the wheels on one side did not hit the planking. Before we could help ourselves the wagon was half tipped over. We could not go ahead. We could not go back. We were simply stuck fast. So we unhitched the horses and went the rest of the way on foot.

When we arrived, Bert's father and the hired man fitted out another team and moved the apiary into the yard, near the house. We boys were a wretched pair to look at, and spent most of the day in slumber. But that did not make us presentable. Only time could do that.

Of the thirty hives of bees, sixteen came through safely. And it may be added that Bert and I have never engaged in the job of transporting bees since that first experience.

[The experiences cited here are by no means unusual. Accidents have occurred more than once in which lives were endangered and much property lost; and it behooves every beekeeper to prepare for the unexpected. No guesswork should be put up with, for the risk is too great. Hives, if old and shaky, should be fastened together with cleats nailed to the covers, bodies, and bottom-boards, and every precaution should be taken to keep the bees from getting out in case a stop becomes necessary.—ED.]

WHITE CLOVER FROM MAY TO OCTOBER

BY L. D. MASSIE

We have had white clover in bloom here since May 4 and there is some in bloom now; but the cold rains and weather kept us from getting much surplus. Spanish needle, goldenrod, and a white flower weed that grows four or five feet high gave a surplus super for extracting and plenty of winter stores.

BEES FOLLOWING OPENING IN THE WOODS.

On page 618, Oct. 1, Mr. Semper speaks of bees not going in a straight line because of the wind. I have hunted bees in the woods since I was ten years old, and have followed a good many bees to their homes in the trees. I have found some beelines that turn and go very near in the form of a triangle. The bees followed openings in the woods.

I believe I can see a bee about twice as far as Mr. Semper spoke of. I have, by running after the bee, kept it in sight across 40 acres or a quarter of a mile.

Somerville, Ind., Oct. 10.

CREATING A LOCAL MARKET

BY FRANK C. PELLETT

Now that the honey crop is harvested, the next question before the beekeeper is how to find the most profitable market for his crop. Few men have a proper appreciation of the possibilities of the home market. When the writer moved to his present location and began keeping bees in a small way there was but a slow sale for even the little surplus produced. I found a beekeeper in the person of John Dufford already on the ground. He was producing a fine article of comb honey, and putting it on the market in first-class con-

pose of I found sale for it during the year, but mostly in such small quantities as to be annoying. I did not want and could not afford to get customers by cutting the price, for the price was already too low. I had no intention of shipping the few hundred pounds that I had to offer to some other point, but determined to create a market. Accordingly about the third year I put extracting-supers on a few colonies, and put up the product in quart jars. I chose the Schram jar, as it is of clear glass. I find that the honey sells much more readily in these jars than in the Mason jars, partly because of the more attractive top and partly because of the clearer glass, which makes the honey look much more attractive. The merchants were skeptical about extracted honey. People would not buy it, they said. I remember how hard I found it to make a deal with one merchant by which I left half a dozen jars to be sold if possible; and if not sold, to be returned. The first season the sale was slow, but I kept it constantly on display in a favorable situation in several of the stores. Sometimes I sent a liberal sample to persons who might prove valuable customers. The second season I produced more extracted honey and it sold better.

Now I sell all I can produce through one merchant, and do not have to bother about peddling it around. I now work my few colonies nearly altogether for extracted honey, and leave the comb-honey market to Mr. Dufford. Instead of injuring his market I have helped it, and the price has constantly tended upward. Last year I sold about 2000 pounds, nearly all through the one store, and our supply ran out several weeks before the new crop came in. This honey advertising has also helped the store with its other lines, and helped to enlarge their trade. They tell me that they have several regular honey customers who live in Des Moines and Omaha, but that they have become accustomed to our honey, and feel sure of the quality.

This fall at the county fair there was a special exhibit of Atlantic-made goods. The local factories had their lightningrods, wagons, brick, tile, and other goods on display. I prepared an exhibit for my grocer also. An observation hive was used to attract attention to the display. About one hundred pounds of honey was put up in pint, quart, and two-quart jars. Behind the whole was placed a large sign appropriate to the place where the exhibit was placed. It read as follows:

Frank C. Pellett, State Bee Inspector of Iowa.

dition. As would be expected, he had the cream of the local trade, and his customers were so well satisfied that they seldom even asked at what price a competitor was selling. If asked about honey they simply replied, "Dufford always supplies us with what honey we use." Most of the stores also were supplied from the same source. As I did not have a large quantity to dis-

Apiary of American hives belonging to F. Richter, Pottenstein, Austria.

PURE EXTRACTED HONEY
 Gathered by Cass County Bees from
 Cass County flowers,
 expressly for
 Stier Grocery Co.,
 Atlantic.

A label somewhat similar was pasted on each jar. No one was placed in charge of the exhibit to take orders; but the secretary of the commercial club, who had general charge of all the exhibits, remarked that this exhibit attracted more attention than any thing else in his charge. As a result of this advertising the sales increased so much that the honey we had put up and regarded as sufficient to last the trade until near the holidays was sold within a month. Many new customers are added every month, and this season's crop bids fair to be sold through one grocery before Christmas. Four years ago we could not sell one-fourth as much through six or seven stores in the same length of time.

Instead of having to ship honey to the central markets, or having it a drug on the market at unprofitable prices as formerly, the local stores now take all the honey produced by the several beekeepers in this locality at profitable prices, and ship in honey from abroad to supply the demand long before the new crop comes in. I have not sold comb honey for less than 15 cents

per pound for three years, although I will not produce any hereafter. I get 12½ cents per pound for the extracted and the grocer furnishes the containers. The retail price is 30 cents each for pint and 50 cents for quart jars. I think that Mr. Dufford has found an equal advance in the demand for his comb honey, though he has used somewhat different methods to increase the sales.

There is no doubt in my mind but that the demand can easily be created for far more honey than is now produced, which can have but one result—higher prices and readier sales. It is an easy matter to create a market at one's own door if only a little ingenuity be used in calling attention to the product, putting it up in attractive packages, and delivering a uniform quality. The same principles apply to other produce. This season there was an enormous stock of plums in western Iowa, and thousands of bushels rotted on the ground. We sold ours readily by packing them in small baskets similar to those that the finest western fruit is retailed in. At the same time, fine plums in ordinary half-bushel market baskets were rotting in the same store not ten feet away. One great secret of successful marketing lies in putting your product in a package that will look attractive to the buyer, and at the same

time putting up a quantity just sufficient for immediate use, as most people buy in small quantities.

Atlantic, Iowa.

[There are great possibilities for one who has the ability and the time, to develop the home market. Sometimes a locality is found where not one family in a hundred buys honey, and there is no demand for it. Advertising then works wonders.—Ed.]

180 POUNDS PER COLONY IN AUSTRIA

BY F. RICHTER

I take the liberty of sending you a photograph of a part of our apiary. We use only Langstroth hives of American manufacture, and are highly pleased with them. There are about 30 colonies in all. Nos. 12, 13, 15, are hives still in winter cases. We had last year a very good honey harvest—about 180 pounds per colony.

Vienna, Aus., Aug. 25.

TEACHING APICULTURE TO BOYS

BY DR. E. F. BIGELOW

I am sending you a photograph showing the good use I am making of the bees in our experimental apiary. I am impressing upon the boys the lesson that bees are not

quite so bad, at any rate at times, as most people regard them. These boys are the sons of wealthy parents of Greenwich who have a special tutor to care for them and take them around, showing them the interests of nature. They requested that I give them a lesson on bees, and this is their first experience. We opened the hive without the aid of veil or gloves, and the boy just in the rear of the hive passed out the frames to his mates. Though they played around with these bees for an hour there were only two stings in the entire company. One little fellow was quite enraptured with the delights of the little insects, which he viewed for the first time as he sat on the ground gazing into the entrance of the hive. I think this a remarkable object lesson that bees are not so bad as they have been regarded.

Arcadia, Sound Beach, Ct.

A CONVENIENT HONEY-HOUSE AND WORK-SHOP

BY JOHN T. SMITH

The engraving shows my bee-yard and work-shop. In nearly the entire yard I use the Hoffman frame. Part of the yard is run for comb honey, and the rest, some 24 colonies, for extracted honey. Last fall there were 110 colonies in the yard. I lost 50 in the winter, so commenced the season with only 60. I have increased to

A group of boys who have found out that bees can be "tamed."

Back-lot apiary in St. Paul, Minn., that produced from 18 colonies, spring count, over 1400 pounds of comb and extracted honey.

100. Part of the colonies that lived through the winter were weak in the spring; but the strong ones have stored beautiful honey from the white clover.

My honey-house and work-shop is 16x24, all in one room. It stands on cement posts 2 ft. high, 18 inches square at the ground, and 12 inches square at the top. There is also one large post under the center where the circular saw stands. The sills are 8x8 sawed timber, with one cross-sill in the center. The studding is 2x4 and 12 ft. high. The siding is matched, and has two coats of white lead and oil. The walls inside are sheeted with matched flooring. The chimney extends down into the lower room.

The work-bench is by the four windows. As I work I can see all the beeyard. The windows hang on hinges at the top, and fold up out of the way.

I have two doors on the end of the building, and in getting supers ready for the bees I pile them in the left-hand doorway, and from there on to the wheelbarrow for the yard. Also in extracting, the frames are brought in at that door. The cement walk leads up to the right-hand door. By this arrangement I save lots of steps in a season. On the screen-doors the screen extends up 6 inches, with $\frac{3}{8}$ strips of wood to form bee-escapes; also outside the windows, the screen extends up to form bee-escapes.

The upper room has a window at each

end, and I open these in the spring and feed the bees ground meal. I also hang frames of honey from the rafters. The bees soon find their way to it, and do not bother in the lower story where I am at work. The material for the building cost me about \$200, and I did nearly all the work myself.

Bellevue, Mich., July 21.

A LETTER CARRIER'S BACK-LOT APIARY

BY L. E. GAYLORD

I am sending a photo of my yard in the back end of my city lot. I had 18 stands, spring count. I have 44 now. I took off 60 gallons of clover honey and 700 sections. I am a letter-carrier here.

St. Paul, Minn., Aug. 21.

BULK-COMB-HONEY PRODUCTION IN CONNECTION WITH MIGRATORY BEEKEEPING

BY J. J. WILDER

In a previous article I endeavored to answer one of the greatest objections to bulk-comb-honey production in the North by mentioning the use of a non-granulating extracted honey for packing the comb honey. In this article I wish to mention another way in which the same result may be obtained—that is, by migratory bee-

keeping, or moving bees at the approach of winter from the North to the South, and operating them for extracted honey in the tupelo-gum sections, then at the end of the flow carrying them back, together with the honey which has been harvested. The return north should be made in time for the honey-flow there in order that the necessary comb honey for the packing of the bulk comb honey may be produced.

This is not a new idea, for there has been almost no end of letters that have come to me from northern beekeepers during the last few years wanting reliable information about a venture of this kind. But neither myself nor any one else could give this information; and as such a trip would be very expensive, no one has as yet undertaken it; but we are now able to give more reliable information regarding the feasibility of this plan.

The A. I. Root Company solved the greater part of the problem the past season by moving a carload of bees from the tupelo-gum section after the flow, then back north in time for the flow, and thereby harvesting a good crop of honey at both ends of the line. Now the question is, "Can bees be brought from the North down, and the project carried out with good results and profit? Of course, this adds much more expense, and makes the problem a more difficult one; but I have taken up the matter with a few of those

who are very anxious to try the venture, and I here give a letter from Mr. George H. Rea, of Pennsylvania, whose location probably represents what would be about the average distance which would be covered in a trip of this nature from the North to the South. The rates given refer to the Okefenoke Swamp in the lower part of Southeast Georgia.

My dear Mr. Wilder:—Your very kind letter is before me, and I am much pleased with the favorable information that it contains. I know that your information is reliable; and from what you have told me I can see no reason why migratory beekeeping would not pay. You ask me to find out what it will cost me to move a car, and then you can better advise. The Georgia Southern & Florida R. R. have quoted me 75 cts. per 100 lbs., 20,000 lbs. minimum per car. That would make the car cost me \$150 besides my car fare, which would be about \$30. So you see it will cost me from \$350 to \$400 to move the car down there and back again in the spring; and in addition to this will be the expense of my boarding and hauling of bees, etc. The probable expense would be about \$500. Is this estimate too high? What can you tell me about living expenses down there? Will the honey crop, gathered there, from 200 colonies, justify this large expense? I should want the bees to pay not only all expenses, but to make some money for me besides.

Reynoldsville, Pa., Oct. 5.

GEO. H. REA.

I think Mr. Rea has slightly overestimated the total expense from the time the bees are prepared for the trip until they have been returned and set on their stands for the flow in the North. Assuming that his estimate is correct (and surely it is on the safe side), that of the entire expense being \$500, let us leave off the last sentence of his letter. I think that the

Smith's mouse and ant proof honey-house and work-shop.

FIG. 1.—A double-walled, air-spaced hive of an old pattern, used to some extent by F. B. Cavanagh, Hebron, Ind.

good climate here and the successful wintering of the bees would amount to more than the actual expense.

The A. I. Root Company's last carload of bees left the Southeast on May 27, p. 374, and arrived at Medina in time for the basswood and clover flows. By May 27 our spring honey-flow from all sources is over. This includes the flows from tupelo gum and gallberry, which last about 35 days, one following the other without any intermission. The average surplus is not less than 40 lbs. each season. Of course the bees must be in fair condition at least to harvest this amount as an average. Based on my own experience, the net amount of honey from 200 colonies would be 8000 lbs.; and at 7½ cts. a pound net it would amount to \$600. Some seasons the sum might be higher, and now and then there might be a season when it would be lower. Now, this would not be a very good paying proposition at this end of the line; but at the other end it might be more profitable if the bees could be landed on their stands there in good condition, for they would surely leave the South in good shape. The hives could be closely extracted before being moved southward, as the spring ty-ty would give a good flow very early, dur-

ing which they could build up and be in the very best shape by the time the heavy flow came on, and some valuable increase could surely be made while here.

Cordele, Ga.

A HEAVY DOUBLE-WALLED HIVE HAVING SOME DECIDED ADVANTAGES

BY F. B. CAVANAGH

In Fig. 1 is shown a hive which, though far from ideal, has some excellent features, and is an especially good winter hive. It is made of $\frac{7}{8}$ material throughout. The outer case is about 18x20, outside measurements. The inside case, or stomach, as it is called, is 16x17½. It contains ten deep frames about 12 inches deep and 15 long. The stomach has a water-table within $\frac{3}{8}$ inch of the upper edge, which supports it on the outer edge of the wall case, allowing the lower edge of the wall to come within $\frac{1}{2}$ inch or so from the bottom-board. The latter is a plain board the size of the outer case, the entrance, $\frac{1}{2}$ x6, being cut in the lower edge of the wall. There is but a scant $\frac{3}{8}$ between the outer and inner cases. The water-table supports the cover, which is shown resting on the edge just under the comb-honey super in Fig. 2.

In Fig. 2 is shown the comb-honey super in place. When tiering up supers, rims of the same dimensions as the lower part of the cover are used to build up to the proper height around the super. This gives the double-wall effect in both hot and cool weather, which is no small advantage.

In Fig. 2 is shown an attempt to produce comb-honey without separators. In the picture are shown some of the best specimens. We had others not so good.

FIG. 2.—Comb honey produced without separators.

FIG. 3.—A cheap hive-stand that leaves room for the toes under the bottom-board.

When I learn the trick it will be time enough to write it. I used $3\frac{5}{8} \times 5$ 7-to-the-foot sections, open on four sides.

Fig. 3 was taken to show our famous I-beam hive-stand, invented by others but original with me. The principal advantages are cheapness, lightness, and a place to put one's toes under the hive when working. Also stray queens can not beguile bees beneath the hive and build combs without being detected, and I believe an open stand rots the hive-bottom less than a closed one.

Hebron, Ind.

HORIZONTAL COMB METHOD OF SECURING QUEEN-CELLS

BY ISAAC HOPKINS

Referring to my letter published Aug. 1, p. 479, and also to the footnote, I wish to say that, if illustrations 1 and 3 had been printed the other way up, as the photo prints were marked, they would have looked much better. As the cells are foreshortened in the photo, they look much smaller than they really were.

PREPARING THE COMBS FOR CELLS.

In the copy I sent I wrote, "I prefer a last-season's-built comb that has *not* been bred in." The word "*not*" was left out when the article was printed, making me say the opposite. By all means use a bright clean comb that has *not* been used for breeding purposes. You will note that I say, "save every fourth row of cells, and scrape out the intermediate

three rows, though the comb in Fig. 1 shows only two intermediate rows scraped out. The illustration shows the comb used in the first trial, which resulted in the jumbled lot of cells shown in Fig. 2. Further experiments convinced me that it would be better to scrape out three rows. KILL ALL EGGS IN THE INTERMEDIATE ROWS.

After cutting down to the midrib beside each fourth row, the intermediate rows scrape out very easily by using the point of a wide bradawl; *but most of the eggs are left behind; and unless these are all killed*

the bees are as likely to build cells over them as over those in the rows, and make a jumble of cells. A small stiff brush, if run along, will kill them. I prefer a splint dipped in wax for killing eggs in cells, rather than a phosphorus match, as I think the phosphorus does harm.

DEQUEENING THE COLONY FOR CELL-BUILDING.

I notice Mr. F. Greiner says, *American Bee Journal* for June, p. 176, "Mr. Dines dequeens about six or seven days before he gives the prepared comb." Our plan, which works all right, requires two for the work. One dequeens the colony chosen, by making a nucleus colony with the queen, two frames of brood, bees, and a frame of food. The rest of the unsealed brood without bees is put into the upper story of a strong colony. The other, in the mean time, is preparing the comb; and when ready it is put at once into the hive for queen-cell building, so that the colony is not queenless for longer than half an hour, and in less than 12 hours the queen-cells are well under way.

RETURNING QUEEN AND BROOD.

Unless we wish to retain the queen in the nucleus colony we return her and the brood to the hive on the fourth or fifth day, usually on the fourth after she was taken from the hive. She, of course, is placed in the brood-chamber with a queen-excluder over the frames, and the cells above, where they mature. There is practically no loss of time, as the queen can

George Edward Newborn, grandson of J. L. Newborn, Snow Hill, N. C. The baby's diet is oatmeal, milk, and honey. He was just two months old when the picture was taken.

lay in the nucleus hive if given an empty comb, and need only be out of the hive for four days.

COMMENTS ON THE FOOTNOTE.

The statement is made that, when more than two dozen cells are raised in one colony, the queens are likely to be short-lived. I say yes, most certainly, if they are raised in small colonies with few nurse bees; but as we raise them in extra-strong two-story colonies in the height of the season, with numberless nurse bees, then there will be 60 or 80 cells containing lots of unconsumed jelly after the queens have emerged, and these queens will be healthy and long lived. Why should they not be? The bees are not unnaturally forced to build cells beyond their inclination by this method; but it is optional with them. Under the conditions mentioned, in the proper season for queen-rearing, there will be a larger number of fine cells built in a natural manner by this plan than by any other I know of.

You say it may be advantageous for beginners and honey-producers who haven't time to learn the intricacies of grafting. I really don't see that there are any difficulties in grafting that can not be overcome in a very short time. There is certainly no trouble without any gain that I can see, unless you count economy in the

number of bees used in raising cells a gain. In my opinion, the grafting system, taken generally, is responsible for more worthless queens than it is possible to calculate. It is possible, no doubt, for as careful a breeder as Doolittle to get the best out of the system; but how many Doolittles are there? Where good eggs are provided, and the cells built over them by the bees in a natural manner in the proper season, one can not fail to get good queens with a minimum of handling and risk.

Auckland, New Zealand.

WHY GRADE HONEY BY ITS COLOR?

The Darker Grades Often the Best

BY HENRY REDDERT

I have often wondered why honey is graded according to the color instead of the flavor. I notice, page 638, Oct. 1, C. W. Ludlow recommends blending to get a uniform color every year. I should think flavor should always be given the preference to color. Why not designate honey as white clover, sweet clover, buckwheat, catnip, dandelion, fruit blossoms, or the name of whatever blossoms it is gathered from? Is it a fact that dark honey is inferior to light honey? Let us analyze it.

The year 1911 was a poor honey year in our district. The spring was cold and wet. Fruit bloom yielded very little. Locust was in full bloom, but the bees had but a few days to work on it, barely enough to keep up brood-rearing. Clover amounted to almost nothing. Dandelion was the only plant yielding a surplus. Now we all know that this plant secretes nectar having the color of the flower, a dark golden hue, called amber, as I understand it. This color brings a second-grade price in the grading rules. But how about the flavor? I have about 90 pounds left, which I would not trade for the best white-clover honey; but remember, I left this honey on the hives until the end of the season, which means that it was thoroughly ripened. Those that had the good fortune to test it, pronounced it the best honey they ever tasted. Color was no object; the flavor is what they wanted.

Locust honey is amber colored, yet I have heard expressions like this: "Honey for the gods." Buckwheat has a dark syrupy color, yet who will say that the flavor is not fine?

Four years ago, all sources failed in this section except catnip, which was very abundant. This honey is very dark—in fact, so dark that a so-called honey expert re-

marked that it was city honey, for out in Indiana where he lived honey was much lighter. He meant, of course, that my honey was adulterated. The fact is, that those local customers I had liked the flavor so well that it was hard to convince them the next season (when most of our honey was white and sweet clover) that the latter was just as good a honey as the former.

We all know that sage honey is as white as any honey on the market. A fellow beekeeper bought several 60-pound cans the year I had the catnip. He and I traded for our own use. He pronounced the catnip honey "*par excellence*." The sage honey was given to one of our neighbors to test. She claimed she liked the catnip (dark) flavor better. To me all honey is alike, provided it is well ripened by the bees. A thick, rich honey sparkling as the morning dew is good enough for any one regardless of color.

I have never heard a foreigner designate honey by color; the flavor is what he mentions. Who will say that our Germans, Englishmen, Scotchmen, and especially our Hungarians (the last named are great honey consumers) don't know good honey? People will buy New Orleans molasses (which is almost as black as coal) only for the flavor. Maple syrup is amber color, and yet who will claim that flavor is not the incentive? Beekeepers have spoiled their own game by advocating color for quality.

Sugar, before we had the present refining process, was yellow, rich in saccharine juices, the very essence of sweetness, but is now white as snow, the best qualities taken out of it. Flour ground in the olden days was amber colored, now white as the miller can make it by taking the gluten, the very elixir of life, out of it. A few years ago I had the good fortune to work with an old experienced chemist. One day he was asked by a catsup manufacturer if he could devise a process to eliminate fermentation. He experimented, with the result that he must take out the ingredients that compose the color of the tomato—as he afterward remarked to me, "The very life of the catsup." If this chemist should take the color out of our dark and amber honey I doubt if there would be much sweetness left. It can be determined only by chemical analysis whether light honey is as rich in sweetness as the darker qualities.

Now what I wish to propound is this: That the consuming public should be educated to prefer flavor to color, thereby setting the darker honeys at no disadvantage to the lighter, and incidentally securing a uniform price to beekeepers in gen-

eral. Beekeepers should also understand that they have no right to ripen honey artificially. Let the bees do this; they are the only ones nature designed for this work.

Cincinnati, O.

[It depends largely upon what the customer is used to. For instance, if the honey "we used to get on the farm" was dark, then the darker grades are usually preferred. On the other hand, if it was light, then the darker grades are not liked as well. Probably the majority of consumers, taking the country over, prefer the milder honey which does not have such a strong flavor as most dark honey has, and yet is just as sweet. We believe our correspondent is right in believing that the color should be a minor consideration compared to the taste.—Ed.]

HOW LOCALITY AFFECTS THE QUESTION OF THE CHOICE OF HIVE

BY C. A. STEVENS

I have been a reader of GLEANINGS off and on for many years, and have been very much amused at the persistency of many of its regular correspondents in the way they put forth their pet hobbies, almost forcing one to believe their method the right and only one. The latest, that of Mr. A. C. Miller, was the best, the way he came back at the Ontario correspondent.

When I started out to become a beekeeper, my father-in-law, Thomas Valiquet, one of the most advanced beekeepers of the Province of Quebec in the 60's and 70's, gave me five colonies of bees (Italians) in Quinby hives, saying that was the best hive yet put out for the Province of Quebec, and that, if I hung to it, and to Italian bees, I would get along all right. For some years I did get along, and had a fine apiary. Moving to Texas in 1882 I could not get Quinby hives there; and as the Langstroth hives were being advocated I changed to that type. So long as I remained in Texas I got along all right; but on returning to Quebec, when I put away 38 colonies the first fall, I lost them all.

My next trial was with the "Jumbo," as this was the nearest I could get to Quinby hives, and I built up a fine apiary again. Then came the Danzenbaker hive. This caught my fancy again, and I bought a lot of them, transferring and cutting my Jumbos down to the Danzenbaker depth. The first year I put 30 colonies into winter quarters in good shape, well stocked

with bees and honey. The next spring I had seven queens, some of which had only a pint or so of bees. They had all starved. I put the seven queens and all the bees there were into one hive and left them to their fate. I had Caucasians, leather, and golden-all-over Italians, Carniolans, Banats, etc. Some time in July I examined them to see what had happened. I found I had a hive full of leather-colored Italians. I tiered it up one by one until it was seven Danzenbaker stories high. In the fall I took off three stories full of honey, leaving the rest for winter. Mrs. S. is also a beekeeper; and, thinking there was too much honey, she took off two more. I fixed the bees on their summer stands, *a la* Miller, and then built a second wall of matched boards all around them, banking them with snow. The next spring the winter broke early; and when I opened them I had a colony full of bees. There was a week of fine weather, then came a heavy fall of snow. When I looked at them again they were all dead—starved to death with not a particle of honey left.

I now had an equipment of over 50 Danzenbaker hives, sections, etc., with no use for them. The next year a neighbor had two colonies of black bees, and he did not want them, so I took them. In the fall I had five full colonies of Carniolans and Italians. Not wanting to throw away my Danzenbaker hives I doubled them up, using two of them for winter quarters; and when I put them in my cellar they weighed 100 pounds—all I could carry. The next spring I put the five out. Two of them, one Carniolan and one leather Italian, were teeming with bees. Two of the others were in fair shape, and the other was queenless, but had a good colony of bees. On the 29th of May the Carniolan swarmed out. I was very much astonished, as there had been nothing excepting the willows for them to work on. When I investigated I found the two Danzenbaker hives full of brood, with plenty of honey, and from ten to fifteen queen-cells in each hive, some of them sealed over. I now had two Danzenbaker hives ready to divide, and a swarm. I moved the two Danzenbaker hives to new stands and put the swarm on the old stand. To-day I took one Danzenbaker section full of the whitest honey I ever saw, and one hive full of the honey—32 sections of 4x5 full, and ten Danzenbaker frames full of the same. There are still two hives with all I can lift ready for winter quarters. That makes three colonies from one, with six hives left for winter, and over 50 pounds of extracted and 32 pounds of sections.

My Italians followed the Carniolans, and I did the same thing with them, making three out of one; but they gave me but little honey.

Our foul-brood inspector was here to-day—the first and only one I ever had visit me in 30 years. I showed him what I had. He said it was remarkable, from the fact that there was but very little honey in Quebec this summer, and that many of the beekeepers were feeding for winter, and had had no surplus. He had been all over the province; had found foul brood in many places, some of it within two miles of me; but my bees have never had it, and I don't know what it looks like. Most of it (in fact all) is where black bees are kept. I keep black bees only long enough to get an Italian queen in their place.

The ideal hive for wintering in Quebec would appear to be two Danzenbaker brood-chambers, thus making a square hive. Mr. Valiquet claims bees, if allowed to cluster where they want to, will be in the center of a hive. That's where mine cluster in the two Danzenbaker bodies—between the two, right in the middle.

St. Lambert, Que., Oct. 1.

BEE PARALYSIS A MOST SERIOUS DISEASE IN AUSTRALIA

Some Glimpses of its Ravages, Showing that it is Not a Simple Trouble to Deal with; Italians Not Immune

BY MAJOR SHALLARD

On p. 332, June 1, Mr. Samuel Simmins has something to say on the subject of bee paralysis. There is only one possible crumb of comfort in the article, and that is where he mentions "a warm curative solution." What is the solution? I want it if it will cure bee paralysis, and so does practically every beekeeper in Australia; but I "ha' me doots." He states that N. S. Wales was visited by this trouble in 1894, and other parts of Australia in 1906. I should like to say that these diseases, though perhaps the same, had different symptoms.

The first I knew of the trouble was when it broke out in California. It was known then as the California trembling disease.

A little while after, it appeared on the Hunter River, N. S. Wales, and afterward spread all through the colony. The affected bees used to come out of the hive, spread their wings with a trembling motion, make short hoppy flights, and eventually give up the ghost. We always got the

trouble in very hot dry weather, and I used to keep a boy going around with a very weak solution of salt water. He used to lift the lids and dash a cupful over the frames of the hives. I used to call this "heat paralysis," and it never did a great deal of harm.

Next we got a more malignant form of the trouble. The bees used to swell up and die in such numbers that there would be from a cupful to a dipperful in front of each hive each day. No colony could stand this strain, and many soon ceased to exist. We used to requeen to effect, if not a cure, at least some mitigation. We were told the disease was in the queen; but I think it was a case of the blind leading the blind.

When I had been keeping bees twelve months I knew all about it, and was ready to put the whole world right. When I had been at the game twelve years I did not know half as much, and I was not at all sure of the correctness of what I did know. Now I have been at it for more than double that time and I know less than ever. One thing I am very sure about, and that is, that I know nothing about paralysis, and that is why I hailed with delight the statement in GLEANINGS that some of your scientists are investigating the disease. It is, without a doubt, the greatest curse that ever struck the Australian bee world.

We know nothing about it; we never know when it will hit us, nor why it comes, nor any thing about it. If a man had asked me twenty years ago how many colonies I had I would have said 800, and I would have been sure about it; but if one asked me now, and also asked me if I were sure, I would become suspicious that he knew something, and I would want to get around the farms soon to make sure. A man never knows what he has. He might have 1000 colonies now, and not 200 in a month.

For instance, one of my farms was giving me an extracting of a little over two tons every month up to last March. About the end of April I went out with the gang to extract again. Not only was there no honey to extract, but the colonies had dwindled until most of them would cover only about three combs. We moved on to the next farm, ten miles away, and the conditions were the same; and a month before they had been rolling the honey in wholesale. Yet the farm I originally started from was all right, and showed no signs of paralysis. The bees were not dead about the hives. There were a few

odd bees hopping about. They had simply disappeared. They went into winter quarters in this state, and I am expecting a big mortality in the spring, which, I am glad to say, is not far off now. I have known a whole farm to die out in a month; and in all of these cases there is any amount of honey in the hives, and often several frames of brood, but no bees.

At one time we only had to see that each hive had enough stores, and we were safe; but now we are never safe for a single month. No wonder I am getting baldheaded; but still I don't growl, you know—just "count your many blessings," and keep scratching along. If this were all the puzzle there is in the matter it would be bad enough; but how do you account for the fact that you can keep bees in one place, and they hardly ever get paralysis, and yet only four miles away you can't keep bees because they get paralysis, and die right out without constant attention? How do you account for the fact that a farm (my own) will get paralysis, and need constant watching, and another, only two miles away, gets none at all? I had a lot of rivals start in the bee business when they saw me getting crops; but they started in this paralysis country, and all the farms died out the first year. I know one man whose bees always had paralysis more or less. He moved some of them into a splendid location so far as bee pasturage was concerned, but, although he gave them constant attention, they nearly all died. I know another man who had over 200 colonies in splendid order on the old site; but he got dissatisfied with the quality of the honey he was getting, and moved the lot to within two miles of the former man. He met the same fate. They all died from paralysis. If it is the feed, why do not both farms, only two miles apart, suffer? or why don't the two farms, four miles apart, suffer? This does not apply to just one small portion, but to parts of Australia hundreds of miles apart. Only last March my bees, 400 miles south of here, were in splendid order, but they suddenly died off, leaving them all very weak to go into winter quarters.

I have been patiently waiting for some other microbe to come along and eat this paralysis fellow up; but he is a long time coming.

To say, as Mr. Simmons says, that bee paralysis will never make headway where the owners use Italians is not correct. I wish it were. I have been keeping bees for my living more than half my life, and I

have always had Italians, and the other people I have mentioned have Italians also; but it has not checked the disease. He says, "It is one of the most simple diseases to deal with." How I wish that were true!

He says Mr. McDonald introduced it by buying infected bees. I will give an instance: On one occasion it suddenly attacked the farms of three beekeepers (queen-breeders whose bees had never had it before). They were all located within a mile of each other. The first one whose bees that got it rushed over to the second, and found that it was there too. He went back to his own farm and fought that disease for a fortnight, when it disappeared. He then, having nine, called on the third beekeeper, who protested loudly that he had not had it; but as he explained to me a couple of days after, his colonies were very weak, and his yard had all been swept with a broom.

Now this visitation hit these three farms at one time, practically on the same day, at one time. Mr. Simmins infers that the disease can be cured by a suitable medicinal agent. Will he give us this agent, or will any one else who knows? I am quite satisfied that, although I have been living with it for years, I know nothing at all about it.

Mororo, N. S. Wales.

POSITION NUMBERED, NOT HIVES

BY H. F. HART

While my system of hive-numbering is similar to Louis Macy's, page 489, Aug. 1, my row number comes first, hive number second; first hive in first row is 11; second hive 12, and so on.

My apiary is arranged in blocks of 10 rows of 10 hives in each. The hives are arranged in pairs, put on stands made of 2 x 6 scantling 4 ft. long, end to end, not side by side, and facing east and west. This allows one to be always working on the south side of the hive, with the sun at the back shining on the frame. But in this way the entrances are further apart

than they would be by Mr. Macy's plan. The alleyways are freer of obstruction for the wheelbarrow.

To facilitate numbering the position of the stand, the number of the row is painted on the fence or a stake, and the hive number is also painted in the same way.

The diagram below shows the arrangement of the hives; and the figures under east and west show the initial or row number on the fence or stake; and the numbers on the north show the hive number painted in the same way. The hives are spaced 6

ft. apart between entrances, and 6 ft. between in the rows.

I have been using this arrangement of hives for the past five years, and the numbering for ten or twelve or perhaps more; and after laying out some twelve or fourteen apiaries in the last 25 years I would not change either the method of numbering or the plan for the hives. I have this method in use in an apiary of 350 colonies now.

Allenville, Ala.

A STRONG COLONY WITH PLENTY OF STORES WILL STAND ALMOST ANY KIND OF WINTER

BY L. M. BROWN

I was a disciple of Mr. A. I. Root when he took an active part in apiculture in the 80's, and I should like to give the "gist" of some of his advice on wintering.

Have booming strong colonies, then select four combs holding in all at least sixty pounds of honey, and crowd the bees down on these four combs, using a chaff division board on each side.

I formerly had the two-story chaff hive

and filled the upper story with a chaff cushion, and I found by experience that a good colony so arranged would pull through ninety-nine times out of a hundred. Talk about condensed moisture! A strong colony so cared for has no room for anything like that. In some of my weaker colonies I found some condensed moisture, but not enough to hurt any thing.

The new double-walled hives are an improvement, I believe, over the old two-story chaff hives and will answer just as well; but let me explain that Mr. A. I. Root used to insist on oat chaff. Take a box of oat chaff and another of wheat chaff, and on a zero day thrust your hand down into each and see which hand feels the more comfortable.

Here in the Salt River Valley our bees keep up brood-rearing through October and commence it again in February. I generally divide my bees toward the last of February. I am speaking now of the Salt River Valley. There is not a day through the winter when our bees can not fly about if they wish to, although in mid-winter there are sometimes two or three days of rainy weather which confines them.

Apparently, there is no foul brood in this valley, but no one should imagine that we never have any troubles. I divided my colonies on the 23rd of February last spring, and at just the time for the young virgin queens to fly, countless thousands of bee martins filled the air, and but a small per cent of the young queens ever came back. This year I intend to buy what few queens I need. These martins were here twelve or fourteen days, and all of my colonies suffered, some of them becoming very weak in field bees. But even if there are no bee martins to catch the young queens, I think it is more profitable to buy queens than to try to raise them here, as there are so many drawbacks to a successful mating.

Phoenix, Ariz.

A NEW WAY TO SIFT THE BEES TO FIND THE QUEEN

BY B. KEEP.

Among all the methods proposed for finding the queen, there is none more nearly certain than "sifting." The method of doing it is about as simple and easy as can be. Fix up a wood-frame zinc queen-excluder, with a thin three-inch wood strip, to be attached under one long side of the frame so as to close that much of the perforations, measuring from the outside

of the frame. This is the only extra preparation necessary. Now lift the hive body (containing the colony to be sifted) off its bottom-board, and set an empty body in its place. Lay the prepared excluder on this empty body, having the edge of the three-inch strip against the outside of the body. This leaves an open space along the opposite side wide enough to pass a brood-frame through easily. Set the hive body containing the brood-frames and bees upon the excluder exactly. Remove the outside frame from each side, shaking and brushing the bees back upon the remaining frames. Set one of these frames aside, and put the other into the body below through the opening before mentioned, and push it along on the rab-

bets out of the way. Now move the brood-frames in a mass over to the hive side next to the opening before mentioned; then, beginning with the frame furthest from the said opening, shake and brush the bees off and down on the excluder, one frame after another, putting each, as cleared, down into the under body, pushing each and the preceding frames along out of the way to admit the next. Last of all, put in the frame previously set aside. If care is used, the brood-nest will be transferred from one body to the other without in any way changing the arrangement of the frames.

The smoker should now be used very moderately to drive the bees down sufficiently to see the queen, if she is there. It is not necessary to shake, drive, or smoke the few remaining bees. Just set the body to one side, and they will soon leave. If there is any simpler way to sift for the queen, let us know it.

Hoboken, N. J., April 24.

Heads of Grain from Different Fields

Getting Rid of Drone Comb; the Purpose of the Follower

Does brood comb ever get old? If so, should it be replaced by new foundation?

After an extracting-comb is used repeatedly, should it be changed for a new one?

If so, what is to be done with the old comb? On the other hand, are the old combs more valuable for extracting purposes than they are if transformed into beeswax?

If an old comb happens to become a drone comb at a time when worker-cells are urgently needed, can the drone part of the comb be cut out and a piece of worker comb fitted in?

A short time ago I purchased five fairly strong colonies. The man who sold them to me is not a beekeeper, having bought the bees with the place. How can I tell whether they are the first or second swarms? My colonies are all Italian. What do you think of fig trees for the purpose of shading the hives? I expect to establish my apiary somewhere on the Indian River.

As I am deaf, please tell me how I can tell whether or not the bees are cross.

How often should each hive be examined? How can I tell whether the honey-flow ceases suddenly or is decreasing gradually?

Do I understand that there are no regular bees in robber-traps?

Please explain the value of the follower and the division-board.

Orlando, Fla., Sept. 24.

L. P. JONES.

[If your combs are straight, and if they do not contain an undue proportion of drone-cells, there is no object in cutting them out and replacing with comb foundation unless there has been some disease about your apiary, such as foul brood of either type. If this is the case, it pays to renew the combs, of course, in order to prevent the disease from breaking out again; for the germs of the trouble lurk in out-of-the-way places about the comb in small amounts of honey in some of the cells, etc. It depends upon circumstances whether all the combs should be renewed at once, or whether only a few at a time. If there is no disease, and you are merely wishing to replace crooked or drone comb, you can replace one or two at a time with comb foundation. The best time to do this is in the spring or early summer when the bees are building comb. In this way you do not obstruct the work of the colony to any great extent. If you have a large vat into which you can throw the combs while they are in the frames you can generally get them free from the wires, leaving the wires still in the frames, and then imb the same wires into a new sheet of foundation. If you have no way of melting the combs out of the frames in this manner, you may find it more convenient to cut the wires and then rewire the frames after the latter have been scalded and made otherwise clean.

An extracting-comb, if it is straight, and free from disease, hardly ever needs renewing. In fact, the old combs are tougher and even better than new ones.

You can sometimes cut out drone-cells and fit in a piece of foundation; but the bees are likely to build drone-cells again around the edges of the patch, so if a comb has very many drone-cells it pays to cut it out entirely, melt it up, and replace with a full sheet of foundation.

From the description of the bees that you bought, we can not say whether they are first or second swarm. About the only way to tell would be to judge of the comparative strengths of the colonies; for if they completely fill the hives so that the hives are boiling over with bees, as the saying goes, it is probable that they are first swarms or parent colonies that have cast but one swarm.

Fig-trees would probably be all right for partial shade, although we do not know that we have ever seen them so used.

If the bees are cross, you can tell very quickly by the way they fly up and attempt to sting when you are handling the combs.

It depends on circumstances as to how often a colony needs examination; but ordinarily it should be looked over once in two weeks any way,

to make sure all is right. When the honey-flow suddenly ceases, the bees become much more irritable, and the bees stop flying into the hives in that industrious manner that they have only when they are gathering honey.

Robber-traps may catch a few innocent bees as well; but they get the robbers mainly, and prevent them from flying.

The follower in a hive should be used close to the outside frame when there are not the full number of frames in the hive, to prevent the bees from bulging that comb. It is also very convenient when the full number of combs are in the hives, for it is easily removed, and then there is space to pry the other frames apart. If the frames completely filled the hive, it would often be difficult to remove them. The follower is also sometimes called a division-board. A chaff division-board is a thicker one padded with chaff for use during the winter as additional protection.—ED.]

The Shaken-swarm Plan; Has it been Abandoned? the Doolittle Method

As I desire to produce comb honey exclusively, and also to establish an out-apiary soon, I have for some time been studying the best methods for operation, and am very much impressed with the plan given by Doolittle in his "Year's Work in an Out-apiary." But in the bee journals of the past few years, some doubt has been thrown on the shaken-swarm method previous to preparation for swarming. This is Doolittle's strong point, I believe. In view of the fact that he did this work during the years 1905 and 1906, I should like to know if the following years' experience on his part, or, in fact, on the part of any large apiarist, has proven this policy to be "laid on bed rock." If there are any modifications of his plan as then outlined, please let us hear of them.

Toronto, Ont., Sept. 16. CHAS. E. HOPPER.

[The shaken-swarm method is just as effective in every way. It is true, there has been less said about it in the bee journals, and possibly that fact might make it appear that no one is using it now; but, as a matter of fact, we believe that some of the best honey-producers in the country are still using it. It is invaluable to the professional man who has to be away from the bees practically all day, because he can practice it at any time that is convenient—on Saturday afternoon, early in the morning, or in the evening when he is at home; but there is no use in attempting it until the bees have made some preparation looking toward swarming. Mr. Doolittle makes that point quite clear.

With regard to Mr. Doolittle's having tested out his method during 1905 and 1906 if we remember correctly he did try it out with practically the same results. But we may say this, that the Doolittle method of shaking swarms can not be carried out very satisfactorily unless there is a fall flow like buckwheat. You remember, if you followed out the method, that Mr. Doolittle arranges to have a large number of combs of sealed honey in the fall. These he carries over until next year, and then gives to the bees in order that they may feel "rich in stores."

With regard to the question of whether others have tried this same method or not, we may say that we have had a number of reports from those who have tested it; and wherever there is a fall flow of honey the method seems to work out well in the hands of others as well as those of Mr. Doolittle. In this connection we should be glad to get reports from those who have tested out the Doolittle method of producing comb honey as well as controlling swarming. Surely, during all these years, there must have been a very large number who have tried it, and can, perhaps, now give us some very interesting data.—ED.]

Eucalyptus Burned

Brush fires swept away the eucalyptus forests last autumn all through this district, and ruined the prospects of this season's honey crop, besides burning 15 colonies of bees with abundant stores.

Hahndorf, South Australia, Aug. 7. J. J. DARBY.

Is the Fact that the Bees Gather Pollen Proof that they Have a Queen?

I have had some success with my bees. A swarm issued Sunday, June 30. Four days later I removed two supers full of clover honey, but eight of the sections were not thoroughly capped. I have just taken a super from the parent hive. The honey is a bright yellow, which I presume is sunflower, as there is quite an abundance of this in this vicinity, and it yields well. Asters and goldenrod are not so plentiful. Ten days after hiving the swarm the bees were working on the eighth frame. Three days later they were filling out the foundation on the tenth frame. I then put on the remaining super. I thought that last super would come off full too, but not so. The best the bees could do was to give me four boxes fairly finished with a little in seven more.

I have given two-thirds of my honey away to my neighbors. They have all come back wanting to buy more. When I told them there was no more, and that they could get it at the grocery, they all said that they didn't want that kind, as it was manufactured honey!

When removing the first two supers no honey-board nor bee-escape was used. I had a troublesome time getting rid of the bees. I smoked, shook, and brushed them until I was tired. With the last two supers I used a Porter bee-escape and board, which I found much better. I am now preparing for winter. Both hives are completely filled with bees, with the brood-nest full of stores.

Is it not a sure sign, when pollen is coming in, that the queen is laying without opening the hive? Brooklyn, N. Y., Sept. 25. DENNIS HEWITT.

[When bees are bringing in pollen it is almost a sure sign that they have a queen; but it can not be regarded as a positive sign, since there are occasional reports of queenless colonies that gathered pollen.—ED.]

Fermentation of Comb Honey

Some of the beekeepers in this vicinity have had much trouble this season with fermentation of comb honey. None of us have ever had any difficulty of this kind before. I have found considerable fermentation in the hive where all of the honey was thoroughly ripened. All of it was of a light-amber color. None of the dark poplar, clover, or sumac fermented. We are at a loss to know the cause. Mine was kept in a warm well-ventilated place as heretofore.

Helena, Ark., Oct. 7.

S. A. FULLER.

[This is a little unusual, although several times before we have heard similar reports from different parts of the South. Who can throw some light on the question?—ED.]

"Automatic" Hiving, Etc.

On page 271 is a photo of a man hiving a swarm automatically, which reminds me of a brakeman on the train from Syracuse to Auburn telling me he set a new hive at Lyons, N. Y., close to the trunk of an apple tree in the morning before leaving, and in the evening, on his return, he learned from his wife that a swarm came out that day, and clustered on the said trunk low down, and gradually crawled into the hive.

Mrs. Luter, of Beaverton, near Orvillia, left her 13-year-old inexperienced uninterested daughter home one holiday, July 1, to watch the bees. Of course a swarm came out, and it clustered low down on a currant bush, so she donned a pair of fur mitts and a miserable veil and hat, and set a hive about a yard away. Of course, they did not find it. Little Britain, Ontario. FERGUSON WHITESIDE.

How Much Syrup Must be Fed to Make 20 Lbs. of Sealed Stores?

I have several hundred colonies of bees that need feeding more or less, and I should like to ask how many pounds of feed would have to be given to a colony to supply it with 20 lbs. of ripe stores. If it is not too late, how about the following proportions? Boiling water, 1 part; cane sugar, 2 parts; one-third as much honey as water. I should like to have you furnish me with some figures as a

basis to work on, and hope to hear from you at once.

Janesville, Minn., Sept. 16. E. L. HOFMANN.

[It would take about 23 or 24 pounds of syrup, made one part water, two parts sugar, and one-third as much honey as water, in order to make 20 pounds of ripe stores. A well-evaporated syrup will contain about 20 per cent of water and 80 per cent of sugar. But a syrup would not be too thin if it contained 25 per cent water and 75 per cent of sugar. In that case you would not need to mix quite so much of the syrup made on the formula mentioned.—ED.]

Second-hand Kerosene-cans Seldom Used for Honey in Australia

On page 455, July 15, Major Shallard says, "Practically the whole crop of Australian honey is put up in second-hand kerosene-cans." Now, I think Mr. Shallard must be quoting from what was in vogue 12 or 15 years ago, and not at the present time. I also think it is unfair to the Australian beekeepers to have the idea conveyed that we are slipshod enough to put up with the fussing with second-hand kerosene-tins when we can procure good new tins, made purposely for honey, and the little extra expense would be easily offset by the looks of the package and the extra price procured. I feel certain that, if Major Shallard makes inquiries of all the large dealers and commission agents who handle the bulk of the Australian honey, he will find that easily 75 per cent of the honey is put up in tins made expressly for honey. I know of one firm in New South Wales that turns out thousands upon thousands of lever-top honey-tins every year, made exactly like the kerosene-tins in construction, but without the lettering on top denoting that they were intended for kerosene.

Perhaps the major has, on seeing tins of this class on the market when filled with honey, taken them, in error, to be second-hand kerosene-tins by their looks.

I have not time for second-hand tins of any kind myself.

How do you think it would go under the pure-food act if the beekeepers used tins that contain, we will say, Pratt's motor spirits, with the name of contents stamped in the tin, by filling the same with honey and labeling it to that effect? Don't you think it would be misrepresenting the contents?

Stroud, Australia.

WILLIAM BARNES.

A Tribute to R. L. Taylor

I was profoundly grieved to note the death of our old friend R. L. Taylor. He was a rare man—as a statesman, gifted, alert, incorruptible; as a beekeeper, one of the very best; as a citizen and friend, invaluable. It was my wont to visit him and to receive visits from him. I never parted from him without a feeling of sincere admiration, both for the man's ability and his upright character.

I wish to express through GLEANINGS my personal loss, as also my regret that the beekeeping fraternity and the country are henceforth to be without his valuable services.

Sacramento, Cal., Sept. 26.

A. J. COOK.

State Commissioner of Horticulture.

"Coffee A" Sugar No Longer Sold

Referring to page 545, Sept. 1, please tell me what "coffee A" sugar is. Dealers here don't keep anything by that name, but they keep "A" sugar and "C" sugar, both kinds brown. Please let me know soon, as I want to fix up some candy for a few light colonies as soon as possible.

Sterling, Col., Sept. 30.

T. J. LANDRUM.

[Coffee A sugar is the old name for the best white sugar that was known years ago. But since granulated sugar has come upon the market it has supplanted the "coffee A" sugar entirely, so that probably you will not be able to buy it of any of the dealers in your locality. Generally speaking, you would be able to use granulated sugar in any place where "coffee A" is called for. "Coffee A" sugar was granular and white, just like granulated sugar, only it had more moisture in it. The granulated sugar of to-day is perfectly dry, and remains so.—ED.]

Carbon Bisulphide Better than Sulphur

By putting all of the combs from dead colonies into a small close room before they had been exposed to this season's moths, and smoking them thoroughly with sulphur three or four times, the moths have not troubled them except in a few combs. I have looked each comb over separately, after smoking, and have found a number of little dead worms, and from six to a dozen big live worms that the sulphur fumes did not reach. So I have concluded that it will be necessary to look over each comb carefully, and pick out all live worms if I wish to keep the combs from being destroyed. Most of the combs in which I found worms I had taken from hives that were used for bees this summer. I had put them on top to let the bees take out the honey. I believe that if no comb were exposed outside of the tight room after early spring the moths would not bother the combs during the summer; but I would not risk them without an occasional smoking with sulphur. MRS. L. C. AXTELL.

Roseville, Ill., Sept. 24.

[The writer of the above is one of the older beekeepers of whom there are now so few left, and years ago was a frequent contributor to these columns.]

It is probable that the fumes from carbon bisulphide, being somewhat stronger, would do rather more thorough work in fumigating; for, as a usual thing, one application, if the room can be kept very tight, is enough to kill all the larvae of the moth. If there are not too many combs it is better to put them all into a large box which can be covered up air-tight, and put the liquid carbon bisulphide in a shallow dish at the top under the cover.—ED.]

Wintering in a Cellar

For those who winter their bees in the cellar, and who do not like to have the cellar littered up with dead bees, the following may be of interest:

Make a frame four inches deep, the size of an 8 or 10 frame hive. The ends should be solid, and inch strips should join the ends, leaving a space on each side 2 inches wide and 18 inches long, to be covered with wire cloth. This allows plenty of air, and prevents the bees from scattering all over the floor, and still there is plenty of room at the bottom for dead bees without any danger of stopping up the opening. The frame should be set on a flat board without any entrance. This, of course, would call for considerable work where the hives are stacked; but in the spring the hives are placed on the regular bottom-boards, and all dead bees are left in the frame.

Dr. Miller, p. 313 of his book, "Fifty Years Among the Bees," speaks of the odor of dead bees. This is something I have never noticed.

INCREASE FROM TWO TO NINE COLONIES.

The past year has been a very good one in St. Paul and vicinity. White clover yielded plentifully, and the fall flow was very good. All beekeepers report good crops, and increase in some cases doubled. Our own two colonies of last spring increased to nine, with about 325 lbs. of honey from three colonies. We fought successfully American foul brood in three colonies. We will put the bees into the cellar with plenty of stores, and hope for another good year.

St. Paul, Minn.

HARRY G. BRANT.

[Several years ago Mr. Orel L. Hershisser, of Kenmore, N. Y., described a cage arrangement similar to the one you mention for use under the hives in the cellar. A number of others have tried it since, but with not very good results.—ED.]

Locating Hives in Pairs

In commenting on Mr. Fred White's article, page 601, Sept. 15, you say, "Old queen-breeders recognize the importance of having each hive so distinct in its location that the virgin will have no difficulty in finding her own home." Will you please discuss this further? I have little room on a back lot.

Oklahoma City, Okla.

R. S. SATTERFIELD.

[The very best plan in locating an apiary is to have the hives located in pairs, and then make sure that the pairs are not too close together. In a small yard this practically does away with any trouble due to virgins mistaking their hives. In a larger yard

the hives can be located in groups of four, two pairs back to back, with just enough room between to walk around. This is really about all that needs to be done by way of precaution, although some beekeepers go so far as to have different-colored hives, or have the fronts of the hives at least painted different colors. It is a question, however, whether this plan is any better than merely locating the hives in pairs as stated.—ED.]

Will Honey Ripen in Unsealed Cells?

The honey-flow has now ceased, and there are many combs containing honey in unsealed cells. Will this honey be ripe if left on the hive a week after the honey-flow, or can it be carried into the honey-house to ripen in the combs artificially?

Northfield, Minn.

ANDERSON BROS.

[There is always some question about the condition of honey that is not sealed. If it can be in the hive a week it is very likely that it will be sufficiently ripened; but an exception to this would be if the colonies were not quite as strong as they should be, or if the weather is cold and damp, at which time we should be afraid that the honey would be too thin. Under such circumstances, if you can not leave it in the hives any longer, take it out and leave the combs in a warm, dry room where a current of air will pass over them constantly. This will tend to evaporate the honey further so that it will be fully ripened.—ED.]

Stings Relieved a Man who Had Suffered for Years

Like C. M. Talbot, Portland, Me., whose letter appears Sept. 15, p. 601, I am a believer in bee-stings for gout and rheumatism. I have attended bee conventions, and invariably have I met those who have been afflicted, and have had a permanent cure by means of bee-stings. Several have come to me for treatment. One man in particular who was strong and healthy-looking, had not worked for three years. He had tried numerous doctors, and had then just come back from the hot springs of Arkansas, but could not get any relief. It was three years ago last June. He came to me for the bee cure. To the best of my recollection he came about every third day for treatment. I applied from twelve to twenty stings each time for three weeks. After that time he was able to follow his old occupation as coachman, and is still on the job, having taken no medicine, and having felt only a light attack of rheumatism since. Before the winter sets in he intends taking a light treatment.

Germantown, Pa.

WM. H. SHINGLE.

Bees Eaten by Chickens

Having kept several colonies of bees in my poultry yard for the past twelve years I have noticed every year that some of my chickens begin to eat dead bees. Later they seem to prefer the drones, and still later in the season they simply stand by the hives and snatch off one bee at a time, slam it on the ground, peck at it once or twice, and then swallow it. Finally, both old and young chickens acquired such an appetite for bees that I had to fence off the chickens. I have seen the bees attack them, but the chickens simply twisted their heads around, looked until they found the bees, and picked them off.

Concord, N. C.

W. D. YORK.

Chickens that Eat Pollen-laden Bees

During my 35 years of beekeeping I have had probably 25 cases where chickens would eat bees at the hive entrance when bees would come in heavily laden with pollen. I think they were after the pollen. I have never known chickens to eat bees willfully.

Milano, Texas, Aug. 23.

G. W. BEARD.

Dead Bees in a Well 30 Feet Deep

Bees are reported to have gone down 70 feet into a well after water, Stray Straws, Oct. 1, p. 612. Undoubtedly bees will go anywhere they can after honey or water; but if they go down 70 feet into a well, they are almost sure to chill and not to return. This fall we cleaned a well only 30 feet deep, and found a large quantity of dead bees.

Boicourt, Kan.

D. C. ANDERSON.

Our Homes

A. I. ROOT

When the Son of man cometh, shall he find faith on the earth?—LUKE 18:8.

For what glory is it, if, when ye be buffeted for your faults, ye shall take it patiently? but if, when ye do well, and suffer for it, ye take it patiently, this is acceptable with God.—II. PETER 2:20.

Father, forgive them, for they know not what they do.—LUKE 23:34.

Let all bitterness and wrath and anger and clamor and evil speaking be put away from you, with all malice; and be ye kind one to another, forgiving one another, even as God for Christ's sake hath forgiven you.—EPH. 4:31, 32.

Of course I can not tell how many professing Christians and devout followers of the Lord Jesus Christ are feeling sad—yes, very sad—to note the lack of Christian spirit shown by the various candidates for the presidential chair at this very time. If there is any time in the world when the candidate for an important office should set a good example by showing before the world a gentlemanly and Christian spirit, now is the time. Once more, if Christianity and a Christian spirit is ever needed, it is needed just now. On some of our coins we read, "In God we trust;" but are we not *really* trusting in the biggest fighter? If the fighting were altogether for righteousness, say for the destruction of the liquor business, we might demand the best fighter; but even then we need one like Gideon who was fighting under the banner of the great God above. If I am correct, President Taft has never professed to be a member of any church, although we have been told his leaning is toward the Unitarian faith; and I wish to say to his credit that he did, at least at first, show much of a Christian spirit. I rejoiced to hear him come out plainly before the world and say he *does not drink*, and that in his opinion a President of the United States ought *not* to drink. Roosevelt has, in some of his addresses, said some very good things on the side of Christianity; but, oh dear me! what an example he has set before the people of our land, especially the younger ones! I can not think it possible that one who lives a pure and spotless life before God need ever indulge in such invectives as Mr. Roosevelt has been doing continually. I think that Christian people as a rule have all been pained to see the woeful lack of the Christian spirit between the two great candidates for the presidency. Do we really believe the little motto on our coins—"In God we trust"? Right here I recall that Mr. Roosevelt made an attempt to have this legend removed from our coins; but, may the Lord be praised, the protest from the Christian people, or

I might say from a Christian nation, was too great, and the reading still stands.

Woodrow Wilson, up to the present time, has shown a better spirit than either Taft or Roosevelt, so far as I can learn; but my complaint against Mr. Wilson would be for his faults of *omission* rather than for those of *commission*. While everybody knows, and the whole wide world recognizes, that strong drink at the present time overshadows every other evil in our land, he is silent, evidently handicapped by the party he represents.

In a recent issue I gave the platform of the Prohibition party. Now, this platform is all that can be desired, for it breathes the spirit of "the Lamb of God that taketh away the sin of the world;" and in response to friend Doolittle and others I have been reading Chafin's addresses, and much of the *Vindicator*, *Am. Advance*,* and *Clean Politics*, all Prohibition periodicals. Surely, thought I, I shall "find faith on earth," and brotherly love, in these periodicals; but in sadness I am obliged to say that, in this fierce scramble for office, I see that same unchristianlike spirit shown toward other candidates. I have longed—yea, hungered—to see something of the spirit quoted in our texts. Let me illustrate:

Our pastor in his sermon, last evening, related to us a beautiful fable. As nearly as I can recall, it was something like this: One bright morning, just at the break of day, a gravel walk and a little plant called mignonette were supposed to be having a little talk. The mignonette said to the gravel walk, in a cheery way, "Good morning." The gravel walk replied, "Good morning" in return, and then added, "My little friend, what makes you so bright and cheerful and full of fragrance to-day?"

Now listen to the reply:

"My good friend, I am bright and cheerful and full of fragrance because I have been *trodden upon*."

"Trodden upon?" replied the gravel walk. "Why, how should being trodden upon

* By the way, I am pained to see in the *American Advance* of Oct. 5 a hideous cartoon of Taft Wilson, and Roosevelt. Of course, it is along temperance lines; but I feel sure that the earnest, sober Christian people of our land feel as I do that the President, and, for that matter, a vice-president of the United States should never be cartooned. Even if we do not indorse and in all things respect the *man*, shall we not at least respect the sacred office he has been chosen to fill? "There is so much good in the worst of us, and so much bad in the best of us, that it hardly behooves any of us to talk about the rest of us."

make you happy? I am trodden upon, perhaps, more than any thing else in the world; but the treading only makes me harder and harder."

At this speech the little mignonette nodded in the sunshine, which just then poured over them, and said, "Being trodden upon brings out my fragrance. In this way it makes me happy."

Now, friends, *you* who profess to be live Christians, does being trodden on bring out the fragrance of *your* Christian life? In Luke 6:22 and 23 we read, "Blessed are ye when men shall hate you, and when they shall separate you from their company, and reproach you, and cast you out as evil for the Son of man's sake. Rejoice ye in that day, and leap for joy, for your reward is great in heaven."

Let us now see how this promise fits. When Roosevelt turned against his old friend and comrade in many a political bout, had it the effect of calling out from the President a Christian spirit that was like fragrance before this sin-stained world? I am afraid not; and when people told stories about Roosevelt because he aspired to another term, did he in like manner breathe the fragrance of a Christian spirit and a mind so great that he kept smiling, and kept gentle under severe provocation?

Lest you think I am all the while defending the Anti-saloon League, let us come a little near home. I made a clipping from these Home papers for Sept. 15, and sent it to the editors of both the *Vindicator* and the *American Advance*. They replied courteously, and in a rather better spirit than I expected; but as a matter of course they claimed that the Anti-saloon League was wrong and that they were right. I made extracts from some of their letters and forwarded them to the officers of the Anti-saloon League. Now, wait a minute. The most of the officers and speakers, and especially those who occupy important positions in the Anti-saloon League, are ordained ministers, many of them having for a term of years preached the gospel. Did I find the Christian spirit in their replies that I have long been hungering for? May be I am demanding too much. I will tell you what I wanted to see and what I wanted to hear, and that was something like this: "Father, forgive them, for they know not what they do."

As I have said before on these pages, if the Anti-saloon League and the Prohibition party, the Endeavor Society, the Y. M. C. A., and the Christian people, would unite, the liquor-traffic and the saloon busi-

ness would go down like a rocket after it has exploded in the air. For years past I have begged and pleaded for brotherly love between the temperance forces. I can forgive people for not thinking alike. There is not a single church in our land where all the members agree, and think alike in *every* thing; but they hold together and hang together because of that charity that "thinketh no evil and is not easily provoked."

Do not, dear friends, think for a moment that I am posing as a model Christian. God knows I am far from it. There is only one model and one perfect sample of a man—the Lamb of God who taketh away the sin of the world. Shall we ever have a President who fears God, and who does not fear the rum traffic or any other form of sin and iniquity? Yea, verily; we have God's promise. But this depends very largely on the spirit that you and I show when we are trampled on or unjustly accused, like the little mignonette. It *should* only make us more gentle, and bring out that fragrance which is, before the world, of more effect than any thing else the world has yet known.

THE ANNUAL YELLOW (INDICA) SWEET CLOVER.

Mr. Root:—The annual yellow (or *Indica*) variety of sweet clover has been advertised somewhat as a honey-plant and as a soil-improver. In the hope of saving others disappointment I will say that it has proven a complete failure with us. The seed germinated fairly well, but the plants made so little growth that a person not actually looking for it would scarcely have noticed its presence. The ground upon which we tried it had been heavily limed, and contained soils of several sorts. A portion of the seed was also mixed with soil from a patch of sweet white clover containing nodule bacteria.

As both the white sweet and common red clover averaged a fair growth in the same field, I am led to conclude that the yellow annual is entirely unsuited to this climate. This conclusion I find is confirmed by the recent United States bulletin on sweet clover, it being therein stated that it makes very little growth in sections where the other sorts are usually grown. The Bokhara Seed Co., sweet-clover specialists, speak of it as the "worthless annual," and state that the seed is obtained as a by-product in the cleaning of wheat in some parts of the West.

The lower price at which the seed of this variety is sold has been an inducement to its planting; and since a farmer who has failed with one kind is likely to be suspicious of all, it would seem to the interest of beekeepers to help make its inferiority known.

H. D. TENNENT.
McConnellsville, Ohio., Aug. 27.

The above indicates that the annual yellow sweet clover is not a success in that locality. Now, in drawing conclusions let us remember there are two varieties of yellow sweet clover; and while the annual mentioned above is not a success in his region, it may be successful in other places. We shall be glad to hear from the friends in regard to it.

Temperance

"THE TRUTH SHALL MAKE YOU FREE."

So far as possible I earnestly request that every reader of these Home papers will at once secure a copy of the *Christian Endeavor World* for Oct. 10, and read the article entitled "Religion of Eugene W. Chafin." After you have read that, read the following which I have clipped from his address at Kansas City, August 9, 1911. Our older readers whose recollection reaches back to 1850 will vividly recall all the facts given; and I hope and pray that it may prove to be such a "revelation" to many, as it has been to myself.

ONE STANDARD OF MORALS.

Mr. Chairman, Ladies, and Gentlemen:—

Away back in the forties there was a class of people in this country called Abolitionists. The old abolitionist was the man who said slavery was wrong, and, being wrong, he said it was wrong in every township under the American flag. He was the man who was absolutely right on that question. On the other hand, there was the slaveholder who said it was right, and, therefore, right everywhere. Then we had the irrepressible conflict between right and wrong, and we have that in every moral battle.

WHEN THE IRREPRESSIBLE CONFLICT WAS FIRST DODGED BY CONGRESS.

In 1850 this slavery question became acute in American politics over the admission of California to the Union. When California asked for admission the slaveholders said they would not admit it unless it was admitted as a slave State. The Abolitionist came along then and said it should not be admitted unless it was admitted as a free State. This put the whole question up to Congress. They then had to decide whether they would admit it as a slave State or a free State.

Now, if there is any thing a congressman hates next to being defeated for reelection it is to have to vote upon a question upon which the people are greatly divided at home.

There was one man in that Congress who was in a worse fix than all the rest. He was in a terrible fix, and that was General Lewis Cass, United States Senator from Michigan. He had been the Democratic candidate for President in 1848, and had been beaten by General Taylor, and he wanted to try it again in 1852.

"Now," said General Cass to himself, "if I vote with the North on this question I lose the Southern vote and get licked;

and if I vote with the South I lose the Northern vote and get licked."

So it was up to him to get licked, no matter which side he voted on. What is a poor statesman going to do in a condition of that kind?

THE ORIGIN OF "POPULAR SOVEREIGNTY."

But Cass was a resourceful statesman. He had served his country more than forty years in public office, and in January, 1850, he got up in the United States Senate and made a great speech, laying down the doctrine known in American politics as "Popular Sovereignty."

He said, "Now, senators, this slavery question is a moral question and has no business in Congress." And they have succeeded fairly well in *keeping* morals out of Congress ever since. "Now," he said, "Senators, the way to settle this slavery question is this: Just submit it to a vote of the people over in California; and if they want slavery let them have it, and if they don't, they need not."

("Popular Sovereignty," "local self-government," "Jeffersonian Democracy," "let the people rule!")

DOUGLAS ADOPTS "POPULAR SOVEREIGNTY" NOTION.

California got in under the compromise measure of 1850, and that doctrine was put aside until 1854. Then Senator Stephen A. Douglas, of Illinois, introduced into the Senate a bill which was known in history as the Kansas-Nebraska Act, creating the two territories of Kansas and Nebraska. And you will remember that that great expanse of country out here at that time extended clear to the British line. The slaveholder came over and said, "Senator Douglas, you can't pass that bill unless you provide for slavery in Kansas and Nebraska." The next day the Abolitionist came along and said, "You can't pass that bill unless you have free soil in Kansas and Nebraska."

The whole question was up to Congress again, and Douglas in the same fix that Cass was. He wanted to be President too. "Now," he said, "I will just take this doctrine of Lewis Cass and I will put it into the Kansas-Nebraska Act." ("Local self-government," "popular sovereignty!") And so he did, and passed the bill. That repealed the Missouri compromise, and turned these two territories of Kansas and Nebraska over to local option. And that is all it was.

Popular sovereignty submitted it to a vote of the people to let them settle the

question. That went all right until 1858, when Senator Douglas became a candidate for re-election to the United States Senate for the third term from Illinois, and that summer he got into seven great joint debates in Illinois with a gentleman by the name of Abraham Lincoln; and Douglas laid down his doctrine of popular sovereignty in those debates, and said: "Now, the way to settle the slavery question is to take it out of politics and submit it to the vote of the people. If the people of Kansas want slaves, let them have them; and if they don't, they need not. I don't care whether they vote slavery up or vote it down. Let the people rule."

HOW LINCOLN PUNCTURED "POPULAR SOVEREIGNTY."

That sounds very nice, doesn't it? and it went all right until he turned to Lincoln and said: "What have you got to say to that doctrine of popular sovereignty?"

Well, Lincoln got up, six feet and three inches tall *physically*, but high as heaven *morally*, and said: "Senator Douglas, slavery is either right or wrong, and I hold that slavery is wrong; and, Senator Douglas, if slavery is wrong, I deny the right of Congress, and I deny the right of the legislature of Kansas, and I deny the right of any majority of the voters of Kansas, by popular sovereignty or otherwise, to put a slave where there never was a slave."

What! Denying the right of the majority to decide what is right or wrong?

"Yes," declared Lincoln. "If it is *moral*ly *wrong*, no majority can make it *right*." And then he went on in those famous words: "This nation can not live half slave and half free."

What did he mean by that? That you could not settle that great moral question with two standards of morals.

His illustration was to the point: "You can not settle this question while you have this condition of things: A penitentiary offense to sell a black man *north* of the Ohio River, but as legal as selling Bibles if you sell him *south* of the Ohio River"—wrong on one side of the river, right on the other; wrong on one side of the State line, right on the other—*two* standards of morals.

FROM LINCOLN—TO LORIMER.

After the second debate, Lincoln's political friends got around him and exclaimed, "Now, Mr. Lincoln, you have got to take that position back. A majority of the voters of Illinois and of this nation believe that the majority should rule, right or wrong, morals or no morals." And Mr. Lincoln replied: "I will not take it back.

I am right, and Douglas is wrong." "Then Douglas will beat you for the senatorship." "Perhaps so," retorted Lincoln; "but I will not take it back, even if he does."

Ladies and gentlemen, can you imagine such a thing happening as a man laying aside the senatorship for the sake of being right in the State of Illinois—*now*? Friends, it is a long way, isn't it? from Lincoln clear down to Lorimer!

EXIT "SQUATTER SOVEREIGNTY."

"Ah, but," Lincoln says, "if he gets the senatorship on that issue, in two years from now the fallacy of popular sovereignty will get into the heads of the American people, and he will never be President of the United States." And, if I remember history correctly, Stephen A. Douglas never *was* President; and in two years that doctrine got into the heads of the people, and then what happened?

The Republican party took that doctrine of Lincoln's and made a platform out of it. The Republican party was born upon the proposition of one standard of morals for the entire nation on that question.

And I want you to remember another thing, to keep in mind that, during that whole controversy, Lincoln and his people always dealt with slavery from the standpoint of its being wrong. Two sentences from Lincoln's inaugural address confirm this fact: "One section of our country believes that slavery is right and ought to be extended, while the other believes it is *wrong* and ought *not* to be extended. That is the only substantial dispute."

WHAT SETTLED THE SLAVERY QUESTION.

The whole controversy was over the question of whether slavery was right or wrong. After the Republicans had builded the platform upon that doctrine, then they took the man who had made the issue and put him on that platform, and, thank God, Abraham Lincoln became President of the United States on that platform and on that doctrine, and slavery died.

Did the compromise measure of the constitution *settle* the slavery question when the constitution provided that slavery should go on for twenty years?

No.

Did the Missouri Compromise *settle* the slavery question?

No.

Did the tariff measure of 1833 *settle* it?

No.

Did the Wilmot Proviso *settle* it?

No.

Did the compromise measure of 1850 *settle* it?

No.

Did "Popular Sovereignty" *settle* it?
No.

Did two political parties that stood for it for fifty years *settle* it upon the basis that it was right and could be regulated?

No.

When did you *settle* the slavery question?

When Lincoln came to the front and laid down this great fundamental principle of right and wrong, hitched those principles up to a *new* political party and went to Washington to take charge of the government. And then, one day before Lincoln died he signed his name to the thirteenth amendment to the constitution, abolishing slavery *for ever* in our whole nation; and then you *settled* the slavery question for ever, didn't you?

WHAT SETTLED THE POLYGAMY QUESTION.

I said I was going to show you that this doctrine is as fundamental as the constitution, on settling questions on the basis of one standard of morals.

"But," you say, "that was largely done—i. e., the *bossing* of the job was done—by the Republicans."

How about the Democrats?

It was only a little while after, that the Democrats adopted the same doctrine. Senator Edmunds, of Vermont, looked across this country three thousand miles from his home and saw an institution in Utah called polygamy. He had learned at the feet of Abraham Lincoln that you could not *settle* a great moral question except upon the basis of one standard of morals for the *whole nation*. One day he introduced into the United States Senate a bill which became known in history as the Edmunds Law, which made it a penitentiary offense for a man to have more than one wife at a time.

What did the Democrats do? Walked right straight up and voted for it, just the same as the Republicans. See what an awful jolt Democratic "personal liberty" got when you would let a man have but one wife at a time.

After the law was passed, and officers were sent to Utah to enforce it, Brigham Young protested: "Now, this is all wrong to pass this law without our consent. Take it back to Congress and have a referendum put into it and submit it to a vote of the people. Nine-tenths of the people out here are in favor of polygamy, and what we want is a chance to vote on it." ("Local self-government," "popular sovereignty," "let the people rule!") "In fact," he said, "what we want out here is *local option* on *wives*." Douglas wanted local option on *slavery*, and Brigham Young wanted local option on *wives*!

What did the Republicans and Democrats do?

HOW THE UNITED STATES ABOLISHED POLYGAMY.

Submit it to a vote of the people?

No.

They said "Lincoln taught us the doctrine of one standard of morals for the whole United States. Polygamy is wrong, and it is wrong in every township under the American flag." And they left the law there and said: "You get right up to that law or you will get into the penitentiary."

But Brigham Young cried: "You can't enforce your old law. Nine-tenths of the people out here are in favor of polygamy, and are against your law."

What did you do then?

Let me tell you one thing you didn't do.

You didn't turn the enforcement of the law over to Brigham Young.

You passed an act of congress providing that the President of the United States should appoint all the officers of the courts, and the President appointed Judge Zane, of Springfield, Ill.—sent him out there to be United States Judge. He got a United States District Attorney from Maine, and a United States Marshal from California. He didn't appoint *anybody* to run that court who had ever been contaminated by living with the Mormons.

These officers went out there to do their duty; and one day Judge Zane called his court to order and said: "Mr. District Attorney, are there any cases to be tried?" The District Attorney said: "Yes, your Honor; John Smith, for having twelve wives." The Judge said: "Call a jury." And they got twelve men in the jury box, and the defendant's attorney looked them over and said: "Now, may it please the court, this is not fair. Every man on that jury is a Gentile. There is not a Mormon in the box." So they challenged them and excused them, and got those twelve off the panel, and got twelve more. They looked those over, and they were all Gentiles—not a Mormon on the jury.

You see, it happened this way: The United States Marshal put the names in the box; and when he came to nine Mormons who were opposed to the enforcement of the law, he left them at home with their numerous wives and children, and put the one Gentile on who had only one wife to leave at home. And under that system he sent over *one thousand* of the Saints(?) to the *penitentiary*.

PROHIBITION IN THE CONSTITUTION STAYS PUT.

Well, they left the law there in Utah, and it is the standard of morals to-day in the

whole United States. And that law was effective until the infamous agreement was made between the Mormons and the Republican and Democratic parties—perhaps not parties, but politicians at Washington—that they *might* violate the law in consideration of political favors from the Mormons to the political parties running this government.

HOW UNCLE SAM DISPOSED OF THE LOTTERY.

I want to give you another instance where the Republicans and Democrats recognized and applied the same doctrine: Louisiana chartered the old Louisiana lottery soon after the war. After they got their charter out and were ready for business they discovered that it was a penitentiary offense to deal in lottery tickets in every State in the Union outside of Louisiana!

"Well, now," they ejaculated. "We intend to skin the whole United States in this game. What are we going to do? Suppose we go and interview Uncle Sam." They went down and saw the postmaster. He is Uncle Sam in every town in the United States. They said to Uncle Sam: "What is your standard of morals in these matters of sending newspapers through the mails that have advertisements of the lottery in them, sending circulars through the mail from our lottery, sending lottery tickets through the mail, permitting the people to get postoffice orders in all the States, and sending the money down to us, in violation of the laws of all the other States? *What is your standard of morals on that?*"

Uncle Sam told them: "We have got no law on the subject at all. It is just as legal to send all those things through the mail as it is to send Bibles through the mail."

"All right, we will bring over a ton this evening."

"Very well, just put your stamps on them and we will carry them to every post-office in the United States."

What was the result?

We had gambling in every township in America.

What was the trouble?

We had two standards of morals—a penitentiary offense to deal in lottery tickets in every State in the Union except in Louisiana, and in the whole United States.

What did you do?

You went down and saw Uncle Sam again, and said: "Uncle Sam, we are in trouble. Two standards of morals on the lottery question." He said: "All right. We will fix it." One day Congress passed a bill making it a penitentiary offense to put

a lottery ticket in the mail, or to put a newspaper in the mail that had a lottery advertisement in it, and confiscated the money orders if they bought them for the lottery.

And so you stopped that. Then, when they could not use the mails any longer, what do you suppose they did? What *could* they do under the circumstances?

ABOLISHING INTERSTATE COMMERCE IN LOTTERY TICKETS.

I will tell you: When they couldn't use the mails for that purpose, under the interstate commerce clause of the constitution, they sent their lottery tickets and advertisements by *express*. Did you ever hear of any thing being shipped from wet territory into dry by *express*? (Laughter.) And under the interstate-commerce clause of the constitution. I see you catch on all right.

Then what did you do?

You went down to Washington again and said: "Uncle Sam, we are in trouble again. They are using the interstate-commerce clause of the constitution to ship their lottery tickets by *express* into all this territory where you prohibited the use of the mails." And once more Uncle Sam said: "We will fix them all right."

HOW THE LOTTERY DIED.

So the day came when Republicans and Democrats united and passed a bill making it a penitentiary offense to ship a lottery ticket *across a State by express or freight or afoot or on horseback*; and then you had one standard of morals for the whole United States, and the old Louisiana lottery died, and there is no legalized gambling under the American flag.

Now, ladies and gentlemen, I want to ask you this question:

Haven't I shown to you, by the legislation of fifty years by Republicans and Democrats, congresses and presidents, that all have acted upon the doctrine laid down by Abraham Lincoln, that you could settle a great moral question only when you had one standard of morals for the whole United States of America?

But you say, "That is all right so far as your congress and the president are concerned; but how about the Supreme Court? That is a part of our government." And from the indications of some of the late decisions, it is quite a big part of our government too.

THE SUPREME COURT AND MORAL ISSUES.

When slavery was abolished they went to the Supreme Court on that proposition, and the Supreme Court said they had a right to pass the Thirteenth Amendment;

that they had a right to pass the Edmunds Law making it a penitentiary offense to have more than one wife at a time.

The Mormons went to the Supreme Court with that question. Brigham Young sent his attorney to that great court with his proposition: He said that marrying twenty-one wives out in Utah was a "religious ceremony."

What did the Supreme Court say? Listen to their answer: "It is *not* a religious ceremony in a Christian country; to wed one wife is a religious ceremony, but to marry two is a *crime*," and they said the law was all right.

Then when the law was passed prohibiting all interstate commerce in lottery tickets, they went to the Supreme Court with that question, and they said: "The Constitution says that Congress shall have power to regulate commerce between the States, and here you prohibit it."

What did the Supreme Court say? A unanimous opinion of the nine judges said that that clause of the constitution gave congress the right to regulate the shipment of cattle or dry goods across a State line, but on a moral question it had a right to prohibit interstate traffic entirely. Oh what a splendid decision!

THE STRANGEST CONTRADICTION IN AMERICAN HISTORY.

Ladies and gentlemen, I think I have shown you to-night that this doctrine of one standard of morals is as fundamental in our government, and has been for fifty years, as the constitution itself.

And you have acted upon it in every single instance but one in American history for the last fifty years—not only these three prominent instances which I have related, but in many others.

You have acted upon it in every single instance but one, and *that* is when you struck the liquor problem. And when you struck the liquor problem you said: "We will adopt a rule on this question different from any other." Isn't it marvelous that you were reasoning right on every single question before the American people until you came to the liquor question, and then you have an entirely different standard of morals?

See A. I. Root's Special Notice, this issue.

A TRIP ON A MOTOR-CYCLE TO THE OLD WORLD; BY ONE OF OUR GRANDCHILDREN.

Several times of late the question has come up as to who shall conduct my department in this journal when sickness or death shall cause me to drop it. The following letter from one of our grandchild-

dren, who has been spending his summer vacation in a tour through Europe, might suggest an answer; he was not quite 21 when this letter was written, and it is plainly evident he had no thought that it would ever find a place in GLEANINGS:

Dear Grandma and Grandpa:—I thought of home quite often on the Fourth of July; and, oh how I wish I could have been with you all for the picnic supper! It is the first one I ever missed on the Fourth.

I will first tell you the things you want to know worst. I am well and feel fine, and have been well ever since leaving home. My machine runs finely, and I haven't had a bit of trouble with it. We have saved money a good many times by good fortune—first on our motor-cycle crates; then on our transportation of them from one place to another; and, lastly, on our hotel bills and meals. In London we stayed at a private family with Mr. Boxwell. We had our meals and all for only \$3.48 for the five days we were there. Here in Paris we do even better. We get our rooms for fifty cents a night, and our meals for about fifty cents a day, besides getting our motor-cycles kept for nothing at our hotel. It costs a little more per day, but the accommodations are very much better, and the rooms cleaner.

This afternoon we went by the aviation field, and saw an aeroplane circling around the field. Later we saw one up in the air about three thousand feet high. Yesterday we saw seven balloons in the air at one time. This is a great place for aeronautics. Next Sunday is the day which the French celebrate as the Fourth of July. Hundreds of dirigible balloons and aeroplanes will be in the air at once.

Yesterday we were invited over to Dr. Wiatt's to dinner. He is the pastor of the American Church here in Paris.

Paris is the most beautiful city in the world. I am afraid it is the most wicked city in the world too. The French women are awful. I am disgusted with all that I have seen so far. The time will come when Paris will be taught an awful lesson, with a catastrophe far worse than the San Francisco earthquake. The beautiful buildings, the Eiffel tower, the Trocadero, the Arch of Triumph, and all the rest, will be destroyed as was Rome of old, and only their ruins will remain. It will be an awful lesson; but unless the French people wake up soon it will be too late.

The ride from London to Paris was beautiful. The green fields, sprinkled with red poppies, the stone walls and ivy-covered castles and chateaus, the green hedges, the thatched-roof peasants' houses, are all far beyond my power to describe. The roads in England are particularly beautiful. They are as smooth as a concrete floor; and the little villages with their tiled-roof houses and peculiar chimneys are exceedingly picturesque.

We don't have a bit of trouble in going from one country to another, because we got international passes in London from the automobile association. It was quite a lot of trouble and expense to get the passes, but they will save us untold time and money in the end. All we have to do now is to show our papers, have them look at our pictures, and see if they tally with us; sign two or three places, and we are off again. In about a couple of weeks we hope to be riding along the Mediterranean Sea. It will be beautiful in Southern France and Northern Italy.

This trip is doing me a world of good. For one thing it is making a man out of me, I hope. I am thrown upon my own responsibility, and even have to look after the two other boys to a certain extent. I keep both their machines in repair for them. Mine hasn't needed any attention yet.

We are coming home through Boston—at least Mr. Griffith and I are. We will stay there a day or two before we come on home.

I am sure you won't worry about me. I take good care of myself, and God takes care of me. When I get home I shall be healthier, stronger, and will have seen more of the world, which is a good thing for anybody. I also hope to be of some service to the business over here if I can.

Paris, July 8. HOWARD ROOT CALVERT.

WINTERING IN FLORIDA, ETC.

As so many are asking what it costs to go down to Florida and back, we have asked the Seaboard Air Line to give us present rates for the fall and coming winter. Below is their reply:

I beg to advise you that the winter tourist fares from Cincinnati are as follows: To Jacksonville, \$33.55; to Tampa, \$45.15; to Bradentown, \$46.65.

Tickets will be on sale October 15 to April 30, good returning until May 31. If rates are desired to additional points we will take pleasure in quoting the same.

C. B. RYAN,
General Passenger Agent Seaboard Air Line
Railway,
Portsmouth, Va., Oct. 2.

You will notice in the above that they give rates from Cincinnati to three points in Florida—Jacksonville, Tampa, and Bradentown, the latter being our winter home. If you wish to take a sleeper, the lower berth will be \$6.25, and the upper berth \$5.00 one way. If you leave Cincinnati in the evening you will be out two nights and a day, reaching Jacksonville in the morning. Now, if your train is reasonably on time you will catch the morning train from Jacksonville to Tampa, landing you at Tampa in the evening, thus making 48 hours from Cincinnati to Tampa or Bradentown. The fare from Cleveland, Ohio, to Bradentown, winter tourist, round trip, is \$57.15; but for a "25-day-trip," it is only \$35.50.

Let me repeat briefly what I have said many times for several years: You can rent rooms, furnished or not, good board and lodging, or board yourself, almost as cheaply in Florida as you can here in the North; and some things, especially the stuff grown in the South, is much cheaper than in our northern markets. You can rent places where one can stay for almost nothing up. In fact, quite a few people live in tents all winter in the neighborhood of Bradentown. Others put up some cheap little edifice that may be afterward used for a barn or stable; and so far as getting employment is concerned, any one who is industrious and skillful may be very sure of getting work. Now, I am sorry to reflect on infirm humanity; but there are always in the South more or less invalids who do not seem to recognize that they are unfit for work of many kinds; and some of these poor unfortunate people have an exalted idea of what they are able to do. Let me give you an illustration:

Just now here in the North there is the biggest kind of a demand for help of all sorts. Men, women, and children are wanted everywhere; and a good many times they get almost *twice* what they actually earn, because people are so rushed, and there is such a scarcity of help. Notwithstanding

this, just yesterday a big able-bodied man was around begging, saying he had applied everywhere, and could not get any thing to do. Now, may be I am a little severe, but it seems to me it is absolutely stealing to *pretend* you are working and taking a good man's money for work, and then make only a pretense when you are doing almost nothing. The point is, anybody who has all the time plenty to do, and more too, here in the North, will find exactly the same condition in Florida. A dozen people will be wanting him all at once.

In conclusion, I do not believe I would advise the young and middle-aged who have good places and fair health to go to Florida. But it certainly is a splendid place for elderly people and others who really can not stand the zero temperatures of the North.

Mrs. Root and I expect to start for our southern home on the evening of November 5, after I have cast my vote. We will take a through train that leaves Cleveland at 9 P.M. for Jacksonville, without change.

FLORIDA IN OCTOBER—A LITTLE GLIMPSE OF THINGS.

Perhaps I should explain, before giving the letter that follows, that our town of Bradentown has recently arranged for an electric current during the whole 24 hours, instead of only in the evening, and accordingly I have ordered an electric incubator, of the Cyphers people, so as to be on hand by the first week in November, in order to get it going at once. I wrote my good friend Abbott, who has charge of my "cross-bred" Buttercups, to have a setting of 60 eggs ready for the new incubator. I suppose I can hardly expect a good per cent of fertile eggs or strong fertile eggs just when the biddies are moulting. Here is his reply:

Mr. A. I. Root:—I can save you what eggs you want. The old rooster is all right, and with your hens; but they are moulting, and I am afraid you will not get many chickens. It is taking about 11 hens to get one egg now—that is, the bunch average about 9 per cent. If you are having "cold feet," live in hope. It was 95 at 5 o'clock P. M. to-day in our north room, with both ends and three doors open, and *no fire*. It is 89 now at 7:30. Doesn't that give you a "glow"? Mr. Rappleye came here from southern Michigan, where he went the middle of July. He said there were only six days during his stay there that he did not wish himself in Bradentown. He has become a "cracker," don't you think?

Bradentown, Fla., Oct. 15. D. W. ABBOTT.

"REGULATING" THE SALOON.

We like the Home, temperance, poultry talks, etc. In answer to the plea, "regulate the saloon," some one hit it about right when he said, "You might as well talk about regulating a powder-mill located in Hades."

Editorial

WHAT WILL THE WINTER BE?

LAST winter was, perhaps, the most severe one that has been known in a period of twenty years. According to the general law of average we can hardly expect another winter as hard on bees. Indeed, it would not be at all surprising if we should have an open winter! for a very cold winter is apt to be followed by a mild one.

NEW STATE ORGANIZATION FOR MASSACHUSETTS.

THE attention of our readers is called to the effort that has been started in Massachusetts toward perfecting a State organization, details of which are given on another page. We understand that this is the forerunner of an organized effort among beekeepers of the State to form a strong organization, and wide interest is being taken in it.

BRITISH SOUTH AFRICA PROHIBITS IMPORTATION OF HONEY.

It has been reported (*Rural New-Yorker* for September 21) that the importation of honey and second-hand bee-supplies is absolutely prohibited in British South Africa. The order against beeswax and foundation, however, has been annulled, following a permit from the Department of Entomology. We presume that bees on combs would be prohibited also.

HORSE STUNG TO DEATH.

As a rule, when newspapers get hold of a case where some person or animal is stung they exaggerate it so much in the effort to make a "good story" that little resemblance to the real incident is left. However, in the *New Holland Clarion*, a weekly paper, a writeup appeared of a horse left hitched close to some hives that was stung so badly that it died. While we question whether "the animal's head was literally covered with bees, filling his nostrils and hanging from his nose in bunches and ropes as they do from the hive on a warm spring day," the incident as a whole

appears very reasonable, and serves as a warning to those who may be so careless as to hitch horses right in the line of flight of bees to and from the hive. As this occurred after the honey-flow, undoubtedly, it is no wonder that the horse by stamping or switching its tail irritated the bees, so that they made trouble at once. The horse was so badly stung about the nose and face that it died later.

MORE ABOUT THE HARMLESS BEES.

IN our Oct. 15th issue we mentioned editorially the so-called stingless bees, newspaper comments concerning which have been "boiler-plated" over the country. Editor Digges, in the November issue of the *Beekeepers' Gazette*, throws more light on the question. The exploiter of these bees, a Mr. Burrows, of Loughton, England, has but nine colonies, and it is quite evident that he has merely stumbled on to a strain of bees that happen to be "so gentle that a child can handle them with perfect safety"! Mr. Burrows probably does not know that the same might be said of almost any gentle colony of Italians or Carniolans.

\$10,000 WORTH OF HONEY RULED OUT BY CHIEF FOOD-INSPECTOR IN CINCINNATI.

The food-inspection division of the health department had many condemnations last week, according to the report of Chief Food Inspector R. B. Blume. The honey alone condemned is valued in the report at \$10,000. The report states that this, as well as the other things condemned, were unfit for human food. Besides the honey, here are some of the big items of the report: 5801 dozen of eggs; 1442 pounds of poultry; 876 pounds of meat; 442 bushels of potatoes; 57 bushels of tomatoes; 23 tons of cabbage; 33 crates of cantaloupes; 238 barrels of apples; 37 bunches of bananas; 18 dozen cans of canned goods, and last, but not least, 24,750 pounds of peanuts.

The above clipping from the Cincinnati *Times-Star*, sent us by one of our subscribers, Mr. Albin Platz, of Cincinnati, caused us to write to Chief Inspector Blume for particulars. His reply, which follows, explains itself:

The condemnation of this honey was not due to an adulteration or violation of the food laws; but, owing to a fire in one of our local storage houses, the honey became damaged by being saturated with

a chemical. It was not thought advisable to use this honey as a food product under the circumstances. It was condemned, therefore, as unfit for human food.

R. B. BLUME, Chief Food Inspector.
Cincinnati, O., Oct. 25.

Of late there have been so few attempts at adulterating honey that the consumer in most parts of the country, at least, can buy extracted honey feeling assured that it has not been adulterated.

THE GREAT ABUNDANCE OF CLOVER.

THE reports from all over the country indicate that white and alsike clover are very abundant everywhere. The frequent and copious rains during the past summer—rains that have been continued clear up into the fall—have contributed to an unusually heavy growth of the clovers. In the 27 years in which we have been connected with this journal, we have never known the time when so much clover was reported. Certainly in our own locality there has never been any thing like it. In talking with some prominent beekeepers they expressed the belief that a severe drouth, or a killing one, could not possibly prevent a crop of clover honey next season all together.

DEATH OF JOHN G. COREY.

WHEN A. I. Root dictated the editorial that appeared in the November 1st issue concerning the death of Mr. Harbison, he did not know that another old veteran, Mr. John G. Corey, died on the same day. It is a remarkable coincidence that these two men who had so much to do with starting the beekeeping industry in California should die on the same day.

A picture of Mr. Corey appears on page 520, Aug. 15, and an extended reference to his life was given in the same issue, page 527. It is no little gratification to us that we were able to let this old veteran of our craft see the sketch of his life just before he died. As it turned out it was an obituary of a long life well spent. It is not often that ante-mortem obituaries are given. In this case the subject had the pleasure of seeing that his life had not been spent in vain. He gave his invention to the world. There are not many like him.

In the last two years, the grim reaper has cut down a very large number of beekeepers who were of prominence in the apicultural world twenty-five years ago or more. It is entirely fitting that we who claim to be among the progressive beekeepers of to-day should not forget the work done by these, our teachers, so many of whom have gone to their reward.

SPECIFIC GRAVITY OF HONEY.

A SHORT time ago Dr. C. C. Miller wrote asking why we did not have an article in the A B C and X Y Z of Bee Culture on the subject of the specific gravity of honey. He found under "Honey," for example, where a United States chemist says that the moisture content of a normal honey is 17.70 per cent. "But," said he, "I have not the means of measuring my honey to know whether it is 17 per cent or something else. If you will tell me how much my honey should weigh, *i. e.*, how many pounds per gallon, I could determine very quickly whether my honey is normal or not."

We went to our honey department where honey is being put up by the gallon in gallon cans, and investigation showed that the average extracted runs approximately 12 lbs. to the gallon. While the average gallon can will hold 12 lbs. of *cold* honey, it will hold only 11 lbs. 10 ounces of honey heated up to, say, 135 to prevent granulation. In other words, a gallon can will fall short by about 6 ounces of holding 12 lbs. of honey when it is filled. This shows that specific gravity varies according to temperature; and it is surprising that there should be so great a difference as nearly a third of a pound to the gallon of shrinkage when the honey gets cold, or, we will say, at normal temperature. Many times we suspect that honey, when it is first extracted from the combs during the height of the honey-flow, will not run much above 11½ lbs to the gallon. A part of this light weight may be due to the fact that honey at a temperature of nearly 100 degrees—that is, blood heat, the temperature of the cluster—is 30 degrees warmer than the atmosphere. Often it may be extracted when the mercury shows 90 or 95 in the shade. This alone will make the weight, even if it comes from sealed combs, some three or four ounces short of 12 lbs. to the gallon. But a good deal is extracted during the height of the season when from a third to one-half of the combs uncapped. This means that some of the honey is not thoroughly ripened. For that reason our large producers have found it necessary to store their honey in open cans, either in large vats covered with mosquito-netting or in square cans with the cap removed. In either case, if the honey is stored in a warm dry room, the specific gravity will increase from 11½ to 12 lbs. to the gallon.

In any case, it has been proven beyond any doubt that no extracted honey should be marketed unless it runs pretty close to 12 lbs. to the gallon when cold. Honey that

is of only 11 or 11½ lbs., is liable to sour. In some cases the heavier portions settle to the bottom of the can while the lighter rises to the top. Many a beginner has found to his sorrow that his honey stored in cans was thin, watery on top, and of poor flavor, while that drawn off from the bottom was of fair quality. But the worst of it is, the honey on top begins to sour, and very shortly the process of fermentation affects the whole can of honey. This fermentation may be arrested by taking it in time by heating; but the more the honey is heated, the more it affects the flavor it had.

We do not know what the moisture content of a 12-lb. honey would be; but as a 12 lb. is a normal honey, and as the Bureau of Chemistry finds 17.70 per cent is the amount of moisture in an average honey, the presumption is that 17.70 is the moisture content of a 12-lb. honey.

THE DIFFERENCE IN FLAVOR BETWEEN COMB AND EXTRACTED HONEY.

PERHAPS the average person would say that honey is honey, whether in the comb or out of it. We presume most extracted-honey producers would assert that *their* extracted, in point of flavor, is the equal of the same article before it was taken from the comb. We shall have to admit that a honey that has been thoroughly ripened has the same delicate flavor whether it is in the comb or out of it. If we could deliver the liquid product direct to the mouth of the consumer, before it granulates and is reliquefied, there never would be any question as to the difference between the comb and extracted honey from the same source and from the same colony, provided both had been capped over before their removal from the original container. But nearly all honeys granulate, and granulated honey has a slightly different flavor from the same honey before it goes into the solid state. We believe that most connoisseurs will agree to this. But when the granulated honey is liquefied it may or may not suffer loss of flavor, as a great deal depends on *how* it is done. In the great majority of cases, honey that has been heated will be found to have lost some of its original aroma. This difference, though not perceptible to the average consumer, can be detected by the connoisseur. We are informed that the flavors in honey depend on certain alcohols that reside in very minute quantities in the honey. If this is the case, these flavors would be very easily driven off by too high a temperature or by long-continued heat. Quick heating and cooling, if

the temperature does not go above 150 or 160, as a rule will not affect the flavor. But a temperature of 140 or more, especially if continued for 24 hours, will rob the honey of some of its delicate aroma, and a connoisseur will notice a slight caramel or burnt taste—something that the ordinary consumer perhaps would not detect. Then why should we speak of it? For the simple reason that beekeepers should be warned that, in heating their honey, they should be careful not to overdo the job. We are convinced that there is a science in liquefying honey; and while we think we know a great deal about it we have yet something to learn. One of the things we *think* we know is that honey should not be kept hot very long. It should be heated quickly, and cooled as soon as possible. Ordinary air cooling we find is the equal of cold-water cooling, although we believe there are some who will dispute this. Well, it comes to pass that a great deal of the liquid honey on the market has been improperly liquefied; and therefore will have lost some of its flavor. It follows then that the *average* comb honey will have more and better flavor than the *average* liquid honey.

There are thousands and thousands of consumers who prefer comb honey, and are willing to pay a double price for it. While a part of this preference may be due to education in early childhood, or to education on the farm, where no liquid honey was produced, there is no doubt that there is a real basis for this preference—in some cases at least.

Again, there are some honeys that suffer more from heating than others; there are some honeys that will remain liquid for a considerable length of time without heating. Mountain sage and tupelo are examples. There are other honeys that granulate very quickly, of which alfalfa, basswood, and buckwheat are marked examples. As a rule the consumer can not obtain extracted alfalfa unless it has gone through the process of granulation and heating to bring it back to its original state. The process in the hands of some will deprive it of some of its original flavor. In the hands of others there will be no appreciable loss, mainly because they know how, and that "know how," we believe, consists in quick heating, and cooling as soon as possible thereafter.

Aside from the inherent flavor already residing in the honey, it is proper to observe that beeswax itself has a flavor all its own. This flavor, added to the natural aroma of honey itself, makes a combination that is prized by some of our best connoisseurs.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

ABOUT that queenless-pollen business I think it's this way: If a colony is bringing in pollen it's a sign it has not been queenless long; but when a colony becomes queenless it keeps right on gathering pollen till it has an overstock, and then it stops. I never knew a colony long queenless without having pollen-clogged combs.

MRS. L. C. AXTELL, p. 706, carbon bisulphide, recommended by the editor, is the thing for wax-worms, large and small, as well as eggs; but if it's more convenient for you to use sulphur don't take the time to pick out the big fellows the sulphur doesn't kill, but put gasoline in a little oil-can and squirt it on them.

R. A. WALL uses scraps of galvanized iron or tin for figures on his hives. A right-angled triangle serves for four different figures by having the right angle in four different positions. Squares and parallelograms with their different positions serve for the rest. Certainly cheap, and familiarity may make them look like figures.

HARRY G. BRANT, you may not have smelled dead bees in the cellar with only two colonies, but you surely would with 25 or 100 if you confine them with your wire-cloth frame. At any rate, the bees can smell them, and it would be much better for their health and the health of the family living over the cellar to have the corpses fall on the cellar-floor to be swept up than to have them decaying on the floor-board.

ARTHUR C. MILLER is a trouble-maker, always unsettling something that has been considered settled. Now he says in *A. B. J.*, 305, "The mere adding of eggs and larvæ to a colony with a virgin will almost invariably cause her disappearance." That in face of the fact that for years it has been considered the proper thing to give young brood to a nucleus with a virgin to make her lay sooner. Say, Arthur, I find record of nine cases this year in which I gave larvæ to nuclei with virgins, and in each case the virgins became laying queens. What's that? "Were there no other cases which failed?" Why—er—well, yes; since you insist upon it, there were eight other cases in which the virgins disappeared. But then, virgins have also disappeared when no larvæ were given, so the whole thing is left unsettled. Somebody please settle it. [We referred this question to our Mr. Mell Pritchard, who has raised over ten thousand queens. He says he has never been able to discover that the giving of eggs and

larvæ had any thing to do with hastening the demise of a virgin queen. Indeed, he makes it a practice to give colonies with virgins young brood. Mr. Pritchard is a keen observer; and when it comes to matters relating to queen-rearing we consider him pretty near authority; and yet on the other hand, we acknowledge that Mr. A. C. Miller on general propositions is reasonably correct. Had we not thought so we would not have engaged him in the revision of the new edition of the *A B C* and *X Y Z* of Bee Culture.—Ed.]

SAMUEL SIMMINS strongly asserted that we were losing by using the L. frame instead of his 16 x 10. Then it was shown that the L. frame is really the larger. But Mr. Simmins very properly points out, *Canadian B. J.*, 263, that not the outside, but the inside measurements must be taken, and by that the 16x10 is the larger. He also claims the advantage that his frames are spaced $\frac{1}{4}$ inch wider in winter. But couldn't L. frames have the same advantage? and haven't they had it? One of his claims, however, deserves consideration: The greater depth, and so the more stores *above* the brood-nest. He seems more sure than ever that Editor Root is off in thinking that the size or shape of frame has nothing to do with winter losses, and thinks we should open our eyes to the need of a deeper frame. However that may be, friend Simmins, I happen to know of one apiary where last winter's losses were exceptionally heavy, and the frames were deeper than yours. [As we have before said, if Mr. Simmins were more familiar with our diversified climatic conditions he would probably conclude that the size and shape of the frame is not so material as he seems to believe. The climate of Great Britain is very much milder than that in most localities in our northern States; and the conditions in a mild climate, or one comparatively so, should not be used as a basis for an opinion for other localities where conditions are very different. For Mr. Simmins' benefit we may state that, during the past severe winter (the most severe, probably, that beekeepers here have ever known), the losses were just as severe on one class of frames as any other. For years we followed this proposition, and we, like all others in the United States, have come to the conclusion that the size and shape of a frame do not have very much to do with success or failure in wintering.—Ed.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

That field of buckwheat on the cover page for August 15 looks refreshing to us who never calculate on getting any thing from the crop.

* * *

Nothing in the number for Aug. 15 set my blood circulating so fast as the temperance columns on the last two pages. When will our great political parties progress far enough to dare this hydra-headed monster and smite it to death?

* * *

The weather here in the East was, during August, the coolest for nearly thirty years. It has also been quite wet, making it ideal weather for clover, and we shall go into winter with more clover on the ground than for many years.

* * *

After inspecting for two years I am not surprised at the great variety of opinions in regard to foul brood, for there appears to be a great difference in the virulence of the disease in different localities, and even in the same locality in different yards. Sometimes even in the same yard one colony seems much better able to cope with the disease than another.

* * *

Somehow bees have seemed to be crosser this year than usual. In some instances, while trying to inspect bees I have been actually driven out of the yard. I have found the bees that have been handled most are the gentlest as a rule, and those handled least are the worst. In one case I was driven ten or twelve rods from the bees of a single hive, and still they came at me until I sneaked through a cornfield into an old ice-house where I got rid of them. I never saw the like of them.

* * *

On page 525, Aug. 15, in footnote to N. F. Gardner, the editor of GLEANINGS quotes Cheshire as authority for bees removing cocoons from cells of old combs when they become too small. Now, I will not say they never do this, but I have never seen combs where it looked as if they had; but I have seen many combs where the cells were lengthened to give more room for rearing larvae.

* * *

Mr. P. C. Chadwick, of Redlands, Cal., is trying to solve the problem of how to reach those who don't take a bee journal. I will tell you, Mr. Chadwick. Our foul-brood laws are reaching them pretty fast, and a good many of them will go out of

business pretty soon if they don't wake up. And yet they say in actions, if not in words, "A little more sleep, a little more slumber, a little more folding of the hands to sleep." Their business as beekeepers is almost sure to pass to others who will care for their bees and learn how to contend with foul brood.

* * *

When Mr. Lundgren was in this country last spring, from Sweden, I met him in the State of New York and also in Washington. I told him how both the farmers and beekeepers were greatly indebted to Sweden for a very valuable plant, alsike clover. He did not at first know what I meant, as I had pronounced the name so outlandishly. Then he told me politely how it should be pronounced—all-si-kee—in three syllables, accent on the second. It is doubtless too late to change the pronunciation now in use, but it was a satisfaction to me to know how it is used in its home land.

* * *

On page 331 Mr. Doolittle tells how to foretell swarming by examination of the queen-cells of the hive, but adds that "for the apiarist with from 100 to 500 colonies this task is seldom undertaken." Hold, my good friend; that is just what some of us Green Mountain boys do. It is mighty convenient, where you can visit a yard only once in eight or nine days, to open in and know for sure just what is going on; and if preparing to swarm, check it in some way. Where the bees are used for extracting honey it is not so necessary. In large yards bees do not seem to follow swarming rules very closely. I suppose this is because they get a great deal mixed.

* * *

Mention is made on page 417, July 1, of bees being a nuisance during strawberry time as well as during raspberry and blackberry harvests. I do not believe that bees often do harm to strawberry-pickers or the berries; but as I have raised a good many raspberries I know they will not only work on them but store the juice in their hives for honey; and yet they do little harm to raspberries except to those overripe. But we should remember the value of bees in the growing of raspberries in fertilizing the blossoms. Imperfectly fertilized raspberries are a ragged-looking lot of fruit, and the bees do far more good to the raspberry-grower than harm. [See statement by Wililam Belshaw, p. 740.—Ed.]

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

THE TEXAS BEE BULLETIN.

The editor has already called the reader's attention to the bulletin written by myself, "Texas Beekeeping," published by the Texas Department of Agriculture, Austin, Texas. In behalf of our Agricultural Commissioner, Hon. E. R. Kone, I may say that, since he is much interested in furthering beekeeping, all who desire to know more about this industry in Texas may apply to him for a copy of this bulletin, and it will be sent free of charge. It is somewhat larger than the usual bulletins published, and is really more like a textbook on beekeeping in Texas.

* * *

WEARING WHITE OR BLACK HATS.

This is a subject that has been worn almost to a frazzle, for bee journals frequently relate some experience in which bees have been attracted to black objects, such as stockings, hats, chickens, or dogs. We supposed that, because of the dislike of bees for anything black, the wearing of lighter-colored apparel when working in the apiaries should always be advocated. However, at the last annual convention of the Texas beekeepers we found a beekeeper who actually prefers wearing a black hat at all times when working with the bees, and that for a very good reason. If he wears a light-colored hat, the bees, since he wears no veil, have a tendency to strike directly for his dark eyes. To avert this he wears a black hat, and this in such a fashion that the brim in front is pulled down to a level with his eyes. When a bee makes a dart for his eyes he lowers his head slightly, which brings down the brim of his black hat, and the bee, instead of alighting in his face, hits the hat-brim. This being black in color, and fuzzy, as felt usually is, the bee puts all its vengeance into the hat-brim.

It was also alleged, during the discussion of this question, that wearing a black hat would attract the stinging bees and thus keep them from stinging the operator. Our experiences teaches us to wear lighter-colored apparel, with a good veil, and thus prevent stirring up the ire of the busy little workers who make for us a living, instead of allowing them to kill themselves uselessly on any thing they do not like.

* * *

DIFFICULTY IN GETTING A QUEEN INTO A LAYING-WORKER COLONY.

That item by Dr. Miller, page 504, Aug. 15, in which he says he saw a laying-worker

in the act of laying, is interesting to me, as I have watched time and again without success to see the same thing. Out of the entire number of bees in a laying-worker colony, I once felt sure I had discovered some that were responsible for the eggs on account of their somewhat larger size or appearance, and the fact that their abdomens were distended. But although I marked some of these with white chalk I never caught any of them in the act of laying. If I had had more time I would have placed the colony in an observatory hive where I could watch the bees more closely.

I have never succeeded in getting a laying-worker colony to rear a new queen successfully, even though new brood is given. I have removed the entire lot of combs that contained brood from the laying workers, and replaced them with other combs, some of which contained very small larvæ as well as older brood; but the trouble continues as long as the laying workers remain in the colony. I have succeeded when the colony had not been queenless too long, so that the laying workers did not have too great a start, or when so much new brood was given that the newly hatching bees amounted to a considerable force when compared to the original colony. Simply giving a comb with young brood to a laying-worker colony does much to effect a remedy, according to my experience, as the bees will not rear a new queen successfully. It is also impossible to introduce a queen-cell or a queen to such a colony.

* * *

STUDYING HONEY MARKETS.

One who has never actually investigated or looked thoroughly into the marketing question is incapable of saying much about this vexatious problem. For instance, my own experience, although of many years' standing, may not do the other fellow any good; for, although I have been able to market crops of honey most successfully year after year, the other fellow's market may require a very material change from my own methods.

Recently I have studied the honey market of some of our large cities. It has always been somewhat of a wonder to me why none of the leading grocers in those places handle any of our honey put up in our own regular friction-top pails. Since these are standard-size packages here in Texas and Oklahoma, and since thousands

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

No rain of consequence since early in October.

* * *

There has seldom been a year that has brought as many inquiries for bees, with as few offered for sale, as the present season.

* * *

Mr. J. Ford Sempers, page 618, Oct. 1, questions the line of flight of a bee as being what is termed a "bee line." There is no question about his reasoning under the conditions he mentions; but it should be remembered that bees follow the course of least resistance. When in the open field, with no wind to hinder, they go just about as straight as wings will carry them.

* * *

The question of artificially ripening honey is agitating the minds of New Zealand beekeepers. Some Californians have tried this to their sorrow, and a few are prone to continue the practice. Buyers have been "stung" so often that now honey must have a good body in order to attract them, and you can not get it by extracting nectar and expecting it to make a good grade of honey. Better put on some more combs and let the bees ripen it. They are past masters at the business.

* * *

Riverside County beekeepers have organized a county club with T. O. Andrews president, and H. J. Warr secretary and treasurer. With these two men at its head the new club should succeed. Mr. Andrews is too well known to need any further introduction, and Harry Warr is one of those progressive, energetic young enthusiasts who manage to attend every important gathering of beekeepers. Good luck, Riverside! We have some of your residents in our club. If you can catch any of ours over in that valley, rope them in.

* * *

Mr. Editor, page 647, Oct. 15, you say, "Moreover a carload shipment of bees from Kansas where foul brood is prevalent was kept from being shipped into the State." I am curious as to whether those bees were known to be diseased. If not, on what ground could an interstate shipment be stopped? This sounds something like the rumbling of some of our California County ordinances that seek to prevent the shipment of bees from infected districts or from within many miles of where infection is known to exist.

There is one apiary in this county that has never been known to have foul brood, while within the past ten years no other within miles has escaped it. This owner should not be deprived of his right to move them where he chooses because his neighbors have had diseased colonies.

[Let us hear from Wesley Foster on this subject.—ED.]

* * *

Recently I gave a report of the action of our county supervisors, stating that they had suspended County Bee Inspector Herron. Well, everybody thought that was the last of Herron's *regime*, so petitions were circulated for the appointment of a new inspector, and presented to the board, only to meet with the information that Herron was still inspector; and from what I can learn he is still drawing his salary for office time that he never puts in. If any one should be interested in my opinion of this matter I would say that it is about as dirty a piece of politics as I have known of in this county. There are men on this board who have been on it for years while we have been fighting for Herron's removal. Men who are now on the board promised eight years ago, when we were fighting for Mr. Herron's removal, for cause, that, if complaint was made again, he would be removed without further question. Since that time two grand juries have recommended his removal, and still he hangs to the job in spite of our efforts. Some of these men are up for election this fall; and while this will not reach its readers until after election, I sincerely hope that the voters' district will see fit to let them retire to private life. I have had great respect for the present chairman, and in some respects still have, but he has played politics with us beemen long enough. Some of his friends will doubtless resent this; but I say it without fear or favor.

This only goes to show the need of a State-wide law to regulate the inspectorship and to put it into the hands of the beekeepers themselves. At the last meeting of the San Bernardino County Association we voted to let the removal of Mr. Herron go, and to work for a State law by which we could cause his removal without having to humiliate ourselves before the county board of politicians who think more of their jobs than of our interests. If all beekeepers in California knew what a hard fruitless fight we have had in this county they would back the new law to a man.

Conversations with Doolittle

At Borodino, New York.

WINTER ENTRANCES.

"I suppose it is time that the bees be fixed for wintering. What about the size and location of the entrance?"

"That depends on where you expect to winter your bees."

"Well, I winter about half of my bees in the cellar and half on summer stands."

"For cellar wintering our best beekeepers hardly use what might be termed an entrance, as hives are often piled break-joint fashion, so that nearly the whole of the bottom of the hive is left open over a space the depth of the full hives below, as the ends of any hive on top rest on the ends of two other hives below. All bottom-boards are left off when wintering on this break-joint principle. And, strange as it may appear, the bees will often hang below the combs in a cluster as large as the crown of a hat. This is one of the very prettiest sights, to my way of thinking, that ever greets the eye of an apiarist. To see these great clusters hanging below the combs, all motionless in midwinter, gives an indication of a good crop of honey the coming summer."

"Where hives are not piled on the break-joint plan, bottom-boards are generally used that have a winter side as well as a summer side, the winter side being two inches or more deep, so that, if we say we have an entrance at all, such is two inches deep by the whole width of the hive. An entrance such as is used in the summer would be so small that the bees dying from old age would clog it. Then a general commotion is the result, and the bees worry themselves so that their usefulness when spring opens is badly impaired, if the untimely death of the whole colony is not the result."

"How about entrances for wintering on the summer stands?"

"Where unmolested by the hand of man, the bees, as a rule, cluster between the combs where the last brood emerged, for here are the most vacant cells. And this brood is generally right back from the entrance, and nearer or further off, according to the amount of stores which the hive contains. If the hive is well supplied with stores, then the last brood reared will be close up to the entrance in from three to five combs; but if the stores for winter are light, then the last brood will be in these same combs, but often back as far as the middle of the hive. At these points the bees can cluster the most compactly by

means of the empty cells; and, being surrounded on most sides with honey, and plenty of pure fresh air from the entrance, they are able to pass the winter in safety unless the winter is long, with a period of five to six months without a flight. Such a winter (not of extreme cold, but not warm enough to give the bees a flight), through this long confinement, chronicles the loss of many colonies, no matter what the stores or where the entrance is located. However, even in such a winter a proper and well-located entrance, and good stores, will enable many colonies to pull through in fairly good shape, while, lacking in either, the mortality would be much greater."

"Please tell me what is a proper and well-located entrance."

"I always face my hives south, and keep them thus at all times of the year, for in this way the sun has an equal chance at both of the sides, while the entrance end is always warmed and dried out by the midday sun. I consider this a great advantage where outdoor wintering is practiced. Then, as hinted at before, the entrance should be right in front of the ranges of combs which the bees occupy, so that the air can be allowed to circulate between those combs which the bees are occupying by their winter cluster. Suppose your hives face south; then if the ends of your combs are toward the entrance, which they always should be, to my way of thinking, your entrance should be midway on the south, so that the air will come in directly in front of the cluster. In this way the bees will not want for pure air."

"But suppose you had allowed the entrance to be near the east side of the hive all summer, so that the last brood which emerged was near that side of the hive, and, thinking that better results would accrue during winter, you made the winter entrance at this time of the year on the west side, the air would not come direct between the combs the bees are clustered on, but would have to pass under and around the combs till it arrived in scanty amount where the bees are, in which case the bees would be likely to suffer from want of pure air, resulting in poor wintering."

"My way has been to allow an entrance the whole width of the hive on the south and seven-sixteenths inch deep. The air then can come in between any and all ranges of comb. This, with a windbreak, so that the wind can not blow directly in the hive, has given the best results."

General Correspondence

DON'T MIX HONEY WITH SYRUPS

Enough Suspicion of Pure Honey Already

BY MAJOR SHALLARD

I think Mr. E. W. Peirce's idea of mixing honey with "Karo" or any other syrup, July 1, p. 409, is much to be deprecated. Once let the public mind associate honey and syrup, or honey adulterated by any thing at all, and you will do the industry an immense amount of harm which it will take years of effort to remedy.

In bottling honey for the grocery trade in Sydney (a city of 600,000 people) I came into competition with adulterated honey; *viz.*, glucose (I put this first because it was the basis), sugar syrup, and honey; and as this could be put on the market at a lower price than my pure honey, I found it hard to keep my trade. The trouble appeared to me to be this: That the adults did not eat honey, and the adulterated stuff did well enough for the children; and as most homes have a scarcity of cash, the cheapest got the preference. If these people would only think a little, and realize what future trouble they are laying up for their little ones in liver and kidney disease, through this stuff, I feel sure they would not have it in the house.

There was absolutely no comparison between my pure honey and the opposition mixture, and after the people came to recognize this, the former more than held its own.

At one time I thought of putting a cheap honey (?) on the market to compete with these adulterators. I got a cask of glucose and some sugar, and experimented with various strengths of glucose and various qualities of honey. I found that the darkest (almost black) honey gave the best results. It gave the most cash, and it was possible to mix up stuff (it was *stuff*, it was not honey) that would give satisfactory tests in the polariscope, but there was no more comparison between it and the honey I was bottling than there is between a trust magnate and an honest man. We, my helpers and myself, had bottles of various mixtures all over the place; and continually tasting the stuff made us all sick.

We all got so full of the stuff that any smell of glucose at all used to make us feel ill, and I decided that, if it was not good for me, it was not good for any one else; and so I gave up the idea altogether. I got the manufacturers to take the glucose back, and stuck to the pure honey.

There was never any question about my honey, as it was the product of my own apiaries; but the public became so suspicious about adulteration that I found it necessary to put the following on my labels:

"I will give £20 to any one who can produce a bottle of my Blue Mountain honey which is adulterated."

This settled all argument so far as I was concerned; but they were still very suspicious where other honeys (many of them absolutely pure) were concerned.

For the last few years we have had a pure-food act which is rigidly enforced. Under this act all foods must be accurately described on the label, and net contents of the packages given; but the manufacturers dodge this to some extent. For instance, the honey adulterators put this on their label: "Honey" in large type; and underneath, in very small type, "mixed with saccharine matter." If they put "Honey adulterated with sugar and glucose," the people would not buy, and that is really what it is because it is impossible to get sufficient consistency without the glucose. Some of the manufacturers put the incriminating label under the bottle; but the board of health stopped it. The board of health carries out its duties well and efficiently, and woe betide the transgressor if they catch him. They are continually catching people for diluting milk, and they fine them very heavily—fines being inflicted from £10 to £25. An inspector visited my bottling place one day and remarked with a smile, "Putting up honey and sugar?" I told him if he could find any sugar or glucose on the premises I would make him a present of it, and also of a £10 note. Then I took him down to where several gross of bottles were ready to go out, and told him to read the label. "Now," I said, "you take that bottle home and earn that £20." Well, I could not induce that man to take any honey away at all—not even as a present. But, as I said at the start, if the public once becomes convinced that some honey is adulterated it takes years and years to get the idea out of their heads.

Even now, in spite of the law, nine people out of ten will tell you that "it is not possible to get pure honey in Sydney," which is absolute nonsense, because you can get it at almost every grocery; but you can not make the people believe it. Every now and then, people will come to one of my apiaries and buy some honey, and they will say, "Ah! this is the pure stuff. I can't get honey like this in Sydney,

you know;" whereas tons and tons of exactly the same honey are being sold every year in Sydney; but you can not get them to believe it.

No! take my advice; don't mix honey and syrups up in the public mind or you will never cease to regret it.

Moreo, N. S. Wales.

[We do not understand Mr. Peirce as advocating the selling of a mixture of honey and glucose; we think he would agree with our correspondent that such a plan would prove disastrous in more ways than one. His suggestion, if we understand him correctly, was to publish a recipe or formula, to be used by the consumer only.

Personally we do not like the taste of corn syrup, or glucose, as it should be called, when mixed with honey in any proportion.—Ed.]

AMERICAN FOUL BROOD

A Plan for Simplifying the Second Shaking by Giving the Bees Two Drawn Combs in Addition to Full Sheets of Foundation when They are Shaken the First Time

BY E. D. TOWNSEND

As foul brood exists in 52 of the 72 counties of Lower Michigan, it behooves us as beekeepers of this State to keep well posted along the line of fighting disease or we may wake up some morning and find it too late. No one can make a success of bees in a diseased location unless he learns the characteristics of American and European foul brood, knows how to treat the two diseases successfully, to keep it in check, and to produce a paying crop of honey.

This is my first attempt to write on the subject of American foul brood, although we have had the disease in one of our yards for the past twelve years. Aside from this experience I have helped my neighbors to some extent. Some may wonder why we did not get rid of the trouble before it ran so long. In the first place, we had neighbors close by who had disease among their bees, and there probably was disease among the wild bees in the woods. Then it is easier to talk about eradicating disease than to go ahead and actually do it. It is likely to crop out in the most unexpected places.

It is a question with many whether the spores of American foul brood live long outside of old brood combs or sealed honey. My experience indicates that these spores

soon lose their vitality when adhering to hive sides and fixtures, and I have often thought that the thin coating of honey adhering to new combs after extracting is not sufficient protection to the spores, and that they, too, soon succumb and become harmless, especially after being exposed to the cold temperature of our northern winters.

FOUL BROOD IN EXTRACTING SUPERS.

Some writers think that very few of the bacteria find their way into the supers during the honey-flow; and for that reason not many, if any, adhere to the extractor reel after extracting comb from a diseased colony. I take no stock in this belief, for I am positive that millions of bacteria are carried above by the bees in the process of ripening honey. I will give just one instance to illustrate this point.

One of my neighbors had ten colonies of bees; and as he had secured no surplus he wanted me to work them for him. More as an accommodation than for what I expected to get out of the bees, I consented. The result was that we got a thousand pounds of honey and lost the extracting combs we took there, for we found American foul brood in them later. The amount of honey that we secured shows that the colonies were strong, and that they did not have the disease very bad. As was our practice we used no queen-excluders. The upper stories were put on about June 1, and about August 1 we found many of the combs in the upper stories rotten with disease, for the queen had taken possession of many of the first stories given. After this experience it would take considerable to convince me that few bacteria of American foul brood are carried above into the extracting-combs during the honey-flow. We know that the spores of American foul brood may live twenty years under favorable conditions. Now, what the honey-producers want to know is how soon these spores lose their vitality under unfavorable conditions.

In handling American foul brood it is absolutely necessary that the apiarist provide himself with a bee-proof honey-house. Robbing must be prevented; and the careless handling of bees, causing them to mix from a diseased colony with a neighboring healthy one, must be avoided.

HOW TO INSPECT QUICKLY.

Our working plan is about as follows: Just before the opening of the clover flow, which is usually about June 1 in this locality, we go all over the yard and take from each brood-nest two combs containing the oldest brood. These two are examined very

closely for disease; and if none is found the colony is considered healthy. Each diseased colony in the yard is marked according to its strength in bees. Extracting-supers of white clean combs that have never been used by the queen are given to the healthy colonies above queen-excluders. Those marked "bad" are left as they are until the approach of the honey season, when they are treated as follows.

OUR PLAN IN DETAIL.

Any time during the day, provided robbers are not allowed to get a taste of the diseased honey, we remove from all of the diseased colonies every comb that does not contain brood in a quantity worth while saving. These are extracted, and then rendered into wax. When removing these combs of honey or empty combs, as the case may be, the brood-combs left in the hive are loosened, and spaced a little wider than usual for convenience in handling them later. About every fourth colony, however (we try to select those lightest in bees), is left with the combs spaced as usual, and pushed over to the side of the hive; for in these hives we afterward stack the diseased brood from the other colonies for the purpose of allowing it to hatch.

We now return to the colonies to be treated. Remove the old hive to one side, and in its place upon the same stand put a clean ten-frame hive containing seven frames of full sheets of foundation, and two drawn combs (if it is an eight-frame hive, five frames of foundation are enough). A cover is then put on, and a wide alighting-board put in such a position that the bees and queen will have no trouble in finding their way back into the hive when the combs are shaken. We then shake off the bees that can be dislodged without spilling a particle of honey, using a brush to get the rest of them. These five or seven combs of diseased brood, according to the strength of the colony treated, are now carried to the light colony mentioned above. The light colony will care for the capped brood in three stories; and as we do not care to preserve unsealed brood, as I will explain further on, a colony of this size is large enough for what we want of it.

The two drawn combs given the treated colony really save one shaking, or nearly so, and one day in the time taken for the double shaking plan. It is a fact that, with any method of freeing the diseased comb of the bees, much diseased honey is carried into the clean hive with the bees; and the secret of success lies in one's ability to get the bees free from this diseased

honey before storing any honey in their new quarters. These two empty combs accomplish this result. Let me digress.

MORNING, NOT EVENING, THE BEST TIME TO SHAKE.

For several years I have felt that the practice of shaking bees at night in the treatment of disease is all wrong. It is advisable to treat American foul brood during the honey-flow, and at night, after a day's work in the field, much nectar is stored that shakes from the combs at a mere touch, so that it is impossible to get the bees from the combs without spilling considerable of this thin honey. It is not desirable to let this get into the clean hive. Furthermore, aside from what is shaken out of the cells, the honey-sacs of the bees are full of this thin nectar, in the process of evaporation, so that a more undesirable time to do this kind of work could not be selected.

Brushing bees from diseased combs without first shaking off the majority of them is rather too slow a process. It takes so long to get the bees all off a set of combs that many of them have time to fill their sacs with honey and carry it to the new hive. This we do not want.

In the morning, on the other hand, the honey from the previous day has been evaporated to such an extent that none is shaken from the cells, and the nectar in the process of being evaporated from the previous evening is cured and stored to quite an extent.

Taking advantage of the fact that the honey in the combs will not shake out, and also that the bees have disgorged themselves of the honey in their honey-sacs, we are ready to remove those two combs before mentioned, and it is done as follows:

The first morning after the colony is shaken from the diseased comb we quietly remove the cover of the hive, give the bees a slight puff of smoke, so that they can be handled, and in less than a fourth of a minute, and before hardly a single bee realizes what is going on, they are shaken from these two combs, and three more full sheets of foundation put in their places. The hive is now closed up nearly destitute of honey. One will be surprised at the amount of honey in these two combs after only the one day. Even when there is but little coming in from the fields, the two combs will be quite heavy with honey, showing the need of taking it away.

Some may ask if we do not lose two extra combs by this plan. We do not, for it sometimes happens that we have some undesirable combs that we can use for this

purpose. And in case we do not, we select some of the outside combs from the colonies having the least disease for this purpose. We take those that contain no brood and but little honey. Even if there should be a little sealed honey it will do no harm so long as there is room for the bees to store what honey they bring with them in their honey-sacs when they are shaken from the old combs.

The weak colonies on which the brood is stacked up are treated later in much the same way as described above. I will give full particulars in my next article.

Remus, Mich.

EXPERIENCES OF A FOUL-BROOD INSPECTOR

BY J. E. CRANE

[This is the first of a series of articles describing beekeeping in Vermont as seen by J. E. Crane while serving as State inspector.—ED.]

I know of nothing in the whole realm of beekeeping that will knock the conceit out of an old beekeeper more effectually than inspecting bees and visiting all kinds of beekeepers. Where one least expects it he will find new devices and short cuts as well as the densest ignorance. He will also meet some of the most charming beekeepers who will send him on his way rejoicing, and others whose acquaintance he will not care to court, but whose ways he must put up with.

I was very fortunate when commencing my work as an inspector. I had had considerable experience with American foul brood, but knew little or nothing of the European type except what I had read. My first visit was in a town where this disease had been doing its deadly work for several years, and almost every yard in the place was more or less diseased. One of the most intelligent beekeepers of the town took me to his home; then out among his bees, and in the most kindly way showed me the character of the disease and his method of combating it. I shall ever hold him in grateful remembrance. He also introduced me to some of the other beekeepers whose yards were badly diseased.

The beekeepers of that town are, as a rule, much above the average, both in intelligence and in enterprise; and upon following my advice the locality, within a few months, was practically free from that disease. I know of but one yard there where it exists to-day; but the territory will have to be watched for a few years to prevent its reappearance.

I have often read in our journals that

European foul brood is very apt to break out in yards that have been cured. I attribute this largely to the fact that more or less of the diseased colonies have remained or have been overlooked, forming a nucleus from which the disease again spreads. Even in localities that an inspector has examined with care, and that are supposed to be free from disease, he is apt, upon making a second inspection, to find new yards, which, although small, are large enough to harbor disease and spread contagion.

Our State law requires that an inspector shall visit diseased yards a second time to make sure that directions have been followed and the disease cleaned up—a wholesome provision! But after making careful inquiries I find I have overlooked yards where disease existed. Even if the inspector were able to find and to examine every yard in a section where foul brood exists, yet the danger of contagion from bees that have escaped and have found a home for themselves would still remain in many places.

This home may not necessarily be a beetrée in the woods, as we are accustomed to think, but an apple-tree in the orchard, or the cavity between the inner and outer wall of a deserted house, or even the steeple of a church or the attic of some house whose inmates have never suspected the presence of bees.

One bee-hunter told me of finding colonies in a brush-heap, among stones, and in an apple-tree in a neighbor's back yard. I once took a colony from a neighbor's attic. There is nothing to prevent these wild bees, as we call them, from contracting disease, and, later, from spreading it among bees which have been treated previous to that time. I met three experienced bee-hunters in 1911 who told me that they had found diseased brood in colonies taken from trees. One of these men was an intelligent and somewhat extensive beekeeper who at one time lost all of his bees because of foul brood, and I believe his statements should be taken at their face value.

Now, I think we should not consider any given section cleaned up until there has been time for all of these wild colonies to die off, say two or three years; then if the disease does not reappear in any yard, that particular section may be safely pronounced free from further trouble.

The law of the State under which I have worked makes it the duty of the inspector, when he finds a contagious disease, to visit all apiaries in the vicinity, so that, if possible, he may learn just how large an area

J. E. Crane at work inspecting an apiary.

is subject to disease, and how many apiaries are affected. In the half of the State that I cover I have found five or six such centers of infection that I have been able to locate, and two or three where the disease has appeared and has run its course, destroying all before it, and then itself disappearing. In one such case, after finding almost every yard diseased, I thought it my duty to visit the towns adjoining. The location of these is somewhat peculiar, as the town itself is separated from the towns on the east, south, and west by water varying in width between half a mile and a mile. But as the bees crossed the water freely for forage during fruit and clover bloom I thought I might look for disease. I was, however, most agreeably surprised to find every colony in these adjoining towns free from any taint of foul brood. This experience satisfied me that bees are not likely to carry the disease across half a mile of water. How far they will carry it when no water intervenes I have no means of knowing. I have, however, come to the conclusion that a good-sized mountain will check the spread of disease. In fact, I have some very good proof of it.

Speaking of centers of contagion, one of the worst was in my own county, and consisted of about 250 colonies occupying an area almost equal to that of an ordinary town. These bees were scattered through

eight or ten yards, in some of which almost every colony was diseased. I did not rest until I had learned just how far in each direction the disease was to be found, and had every owner of bees at work making an effort to get rid of the disease. I did not expect that it would all be cleared up the first year; but I believe at least nine-tenths of it was.

An interesting question comes in right here. How far will bees go to rob a colony weakened by disease? I frankly confess that I don't know; but I was told by one beekeeper that they will go three-fourths of a mile. Another had heard of their going $1\frac{1}{4}$ miles to rob other hives.

Disease is also spread by careless beekeepers who leave out of doors, for the benefit of other colonies, the hives in which diseased bees have died. The rank and file of beekeepers do not seem to have the slightest idea of the character of foul brood, nor how to prevent its spread.

The careless use of comb foundation, too, has helped to spread this disease. When a beekeeper has learned the use of comb foundation he often hives swarms that have issued from foul-brood hives on foundation; and the honey carried by the old bees to the new hive, and there stored in the rapidly built combs, often makes trouble later.

Middlebury, Vt.

A MODEL INSTITUTE FOR SCIENTIFIC AND PRACTICAL BEE CULTURE

BY R. LINDE

[In America there are at least four universities at the present time in which bee culture is featured as an elective part of the regular course; viz., the Ontario Agricultural College, the Wisconsin College of Agriculture, the Massachusetts Agricultural College, and the Agricultural and Mechanical College of Texas. In our Oct. 1st issue were several pictures of the buildings and equipment used in the study of beekeeping in Massachusetts. The following article shows the extent to which beekeeping is taken up in a prominent German university.—ED.]

In GLEANINGS for Dec. 15 I endeavored to draw the attention of the fraternity across the water to the work carried on at the Royal Institute for Bee Culture in Erlangen, Germany. It is my privilege now to give a description of this institute, showing how it is arranged and equipped.

Erlangen is a small town in the kingdom of Bavaria, the largest state in Germany except Prussia. Erlangen seems to be noteworthy on account of its university, to the zoological institute of which the Royal Institute for Bee Culture is linked.

Formerly the institute was divided into a scientific and a practical department; but that division does not seem to have been of any advantage generally, for it has been abolished. There are more places in Germany where bee science is cultivated. However, at Erlangen beekeeping as a science is brought into intimate contact with practical bee culture. That is what distinguishes the Royal Institute at Erlangen. So far

as I can conceive, personal ambition (the abscess on the body of German bee industry) has no particular place at Erlangen, where a most sincere desire to render useful service to practical bee culture seems to be the moving power in the main.

GENERAL ARRANGEMENT.

Fig. 1 shows a plan of the institute. The laboratory, Fig. 2, being situated in the building of the zoological institute, is thoroughly equipped with the newest and best instruments and apparatus for carrying out zoological and bacteriological studies. An interesting and very necessary implement is the glass house, Figs. 3 and 4, ready for use in the garden of the zoological institute. This glazed bee-house supplies the bee-material required during winter time, and is divided into a small working room and a large partition where the bees can take their flight. Fig. 4 gives a view of the inside of the bee partition. A few nuclei in single-comb observatory hives are kept here over winter. Branches of hazel, alder, cherry, and similar trees are put into water and come soon into bloom in the glass house, the temperature of which is kept at 64 degrees F. The bees are eager to carry in the pollen thus afforded. The glass house is covered with dim glass, with the result that the bees soon become accustomed to the limited flying space.

THE VEGETABLE BIOLOGICAL PLANT.

This is a very interesting part of the institute, and demonstrates the close rela-

2. The laboratory. 3. The glazed bee-house where bees can take a flight during winter. 4. View of the inside. 5. Springtime bee pasture. 6. Summer pasture. 7. Late-flowering bee plants.

tion between bees and flowers. Three beds (9, 8, and 11, Fig. 1) are occupied with bee-plants grouped in accordance with their flowering time. Thus on one bed you may see the principal flowers yielding nectar and pollen during spring time (Fig. 5). On another bed all the important bee-plants of summer are grouped together (Fig. 6), and a third bed shows late-yielding bee-plants, the most important of which is heather, Fig. 7. Agricultural plants of value for the bees are placed on a bed by

themselves, as in No. 13, Fig. 1, and further beds are devoted to plants showing especially well the intimate relation between flowers and bees.

THE BEE-GARDEN.

With taste and skill the different bee-stands are distributed among the equally well-arranged flower-beds and fruit-trees. The position to the right of the decoration bed, 17, Fig. 1, is occupied by four stands of bees representing four typical races (golden Americans, Italians, Carniolans,

and German blacks). The hives are painted a dazzling white, and thus afford a good background for the colors characteristic of the different races.

On the other side of the decoration bed mentioned is a stand with colonies for experimental purposes that may be seen in Fig. 9. In the foreground of this photo a very interesting watering-device is shown that supplies clean water for the bees when in need of it, as in early spring. On an unpolished plate of granite, placed toward the south, at an angle of 45 degrees, fall drops of water from a pipe having 12 outlets. The plate of granite absorbs the rays of the sun so thoroughly that the temperature of the down-flowing water rises soon to about 76 F., while the temperature of the air does not rise above 43 F.

A very important point in favor of this watering device is the ease with which it can be kept clean. As the water is constant-

ly flowing, the danger of infection is very remote.

Owing to the fact that in this country a great number of different constructions of hives are in use, the institute maintains a special stand (No. 1, Fig. 1) where bees are kept in the more important types of hives side by side. Thus visitors and students have an opportunity to compare the advantages and peculiarities of the different systems. Each hive bears a small plate furnishing all necessary information as to the internal construction of the hive.

On this continent most beekeepers prefer to put their bees into bee-houses. Usually these bee-houses are properly built and neatly kept. Fig. 11 shows a small model bee-house of the common German type. It contains five stands of bees, the hives being placed closely side by side. The space immediately above the hives is filled with hanging windows and flap windows. Above

11. A small model bee-house of the common German type.

8. Different races of bees side by side; 9. Bee-stand for experimental purposes, and the special watering-device; 10. Bees in different styles of hives.

12. Bees in different styles of skeps.

these, just below the roof, there is a box-like construction projecting through the wall (as the photo clearly shows) to accommodate spare combs. The small white painted box on the outside, next to the door, contains meteorological instruments. The working-room of the bee-house is provided with work-bench, washing-stand, oil-stove, and shelves for feeders and appliances.

Skeps are, I think, a rarity on your continent, although I have met people who told me they had taken skeps with them when they emigrated to America. But I suspect those skeps have, in most cases, found a place in the poultry-yard as hens' nests.

In Fig. 12 four of the most common types of skeps are united under an old-fashioned straw roof that corresponds nicely with the character of the skeps. The first skep, on the left, with its trunk-like appearance, contains movable combs held in position by means of pins. The next one has the peculiarity that it can be supered like a modern hive, though its cylindrical shape precludes the use of movable combs.

The editor permitting, I will give, in a future contribution, a description of the way the skeppist treats his bees and gets his honey. I will not neglect to mention that for students there is a special beestand at the institute (No. 20, Fig. 1) on which manipulation

can be practiced and the necessary skill acquired.

The work-shop and store-rooms are close to the bee-garden, and accessible over the stairs *a*, Fig. 1; *b* is a storing-room for timber; *c c* are work-shops in which the students are taught to make hives, etc.; *d* is an extracting and rinsing room; *e*, an office; *f*, a bee-tight comb-chamber.

The museum contains hives and appliances of the past that are of historical value.

Very little stress is laid on honey production, for this garden is mainly devoted to instruction and scientific and practical studies. However, the institute would lose somewhat if the feature of honey production were entirely neglected. For that purpose a few out-apiaries are maintained. One of these is so well situated that it answers all requirements for a fertilizing station for queens. Race culture is the motto in the queen-rearing line now in this country; and by "race culture" it is always the black bee that is meant; all efforts are made to purify and improve the neglected blacks. I hope to be able to devote to this matter a special article later on.

According to its aim and its special tasks the work in the bee-garden is carried on with every precaution possible against the danger of infection. The different beestands are distributed over a large area, and each one is placed on a pavement consisting of plates of lime which are carefully cleansed every day. Combs belonging to different hives are never interchanged; each frame bears the number of the hive to which it belongs. No comb is used longer than two years in view of the fact that

13. Students of a short course held at the Royal Institute for Bee Culture at Erlangen, Germany. 1. Professor Dr. Fleischmann, the director; 2. Professor Dr. Zander, the managing director of the institute.

it is the comb that carries the germs of disease—the more easily the older it is.

A number of short courses are held annually to instruct beekeepers in all branches of the craft. Fig. 13 shows a group of students who attended a short course in 1911. After my description of the institute this photo might be of interest, as it shows, in the midst of the students, the men whose efforts built up the institute and whose spirit permeates its works and doings.

It is, after all, the spirit emanating from such a place of science and practical work that imparts deeper and more lasting results than the teaching of mere science, however exact and wonderful, or the teaching of mere practice, however useful and profitable.

Wendhausen bei Hildesheim, Germany.

COMB HONEY IN TIN SECTIONS

An Entirely New Method of Marketing Comb Honey, Obviating Much of the Loss from Breakage

BY PAUL HUNTEN

Too little attention has been given by the producer to the marketing of his honey. His pretty wooden sections that leave his apiary nice and clean, after passing through

Paul Hunten's super for holding tin sections. Notice that the section-holder fully surrounds the four sections, being somewhat similar to the wide frame.

the hands of several middlemen are apt to reach the consumer with an accumulation of dust that can not be wiped off. This is sometimes barely noticeable to the naked eye, and yet the dust is there. All kinds of crackers and other food products are now put up in separate packages instead of in bulk, and the consumers are glad to pay the extra price for the sake of having the food free from contamination. I know of a case of honey that stood in a prominent place in the only store of a town; and, although it remained there for weeks, the contents were sold very slowly. In order to call attention to the honey it was often taken out of the display package and put in the show-window, where it gathered dust and germs. For some time I had been working on the new plan of using *tin* sections; and as soon as I had fifty pack-

ages off my hives and ready for market in the tin boxes I displayed in this store in competition with the wooden sections; and, though the latter had been on sale for some time, the clerks told me that the entire lot of fifty tin boxes could have been sold inside of an hour.

The three illustrations show my super with the section-holders, and also some of my honey as it appears ready for market. There is absolutely no

The section-holder with the four tin sections slipped out, the end-bars being removable.

Labels, tin boxes, and the finished package ready for market. The tin covers, one of them having a celluloid front, are slipped over the tin section, melted wax being used to make a tight package, and then the label is put on, extending completely around the box.

difference in the storing of honey by bees in wood and in tin. This was proven under my own supervision during a test with 2500 tin sections and as many more wooden sections. All were filled without noticeable difference in the time required.

There seem to be two principal objections

at present. One is the light weight of the honey in the tin sections, and the other is the cost. The light weight will be remedied by the use of fences that are properly spaced to bring the cappings nearer the surface, and to prevent pop-holes in the honey as much as possible.

Vanderwerken's apiary at Stamford, Ct., at close range.

Mr. Vanderwerken in the midst of one of his strong colonies.

The cost is a harder matter to overcome, as thousands of producers will have to become convinced that it is only a reasonable advance, necessitated by a change from an unsanitary to a sanitary package. The labor of putting up the honey seems to be about the same; but the material will naturally and unavoidably cost more. I have mailed sections of honey to various correspondents; and, although it invariably arrives in good condition, the question in nearly every case seems to be whether it will pay to make the change on account of the additional cost.

I find that the tin package complete costs 4 cts. more than the wooden section, which extra cost is offset in a measure by the difference in expense of the shipping-cases, it being possible to use much cheaper corrugated paper cases that will hold 50 lbs. each. Moreover, there will be the bene-

fit of a reduced freight rate on less than car-load rates; that is, the honey in the tin sections goes as fourth-class instead of first-class freight. Some have expressed the doubt whether the railroad companies will maintain this rate; but I think they will, as there will be less cause for claims of breakage than in case of wooden sections.

Somerset, Col.

[It may be said to the credit of our correspondent that he has gone ahead at his own expense in experimenting with the tin sections, making changes wherever necessary, and cutting and trying to find the best combination, all things considered. While perfection has undoubtedly not yet been reached, the matter has gone far enough to deserve careful attention on the part of comb-honey producers.

There is another point not touched upon in the above. Much comb honey is spoiled by being put in a cold,

damp place. In this tin package, owing to the fact that the honey is practically hermetically sealed, there should be little change brought about by unfavorable conditions of atmosphere.

As we look at it, the whole matter hinges on the expense. In other words, will the lower freight rate, the smaller amount of breakage, and the protection from dust and germs, offset the relatively great expense of the package?—Ed.]

MY MOST EFFICIENT AND ENTHUSIASTIC PUPIL

BY EDWARD F. BIGELOW.

In a former number of GLEANINGS I paid my respects to Mr. L. C. Root, the veteran beekeeper of Stamford, Ct., who was my teacher and my inspiration when I first began to study bees. It now affords me

pleasure to introduce to the general public a man well known in Connecticut, and especially in Fairfield County, as the most ardent, devoted, and active beekeeper in existence—a man whom I am proud to claim as my pupil. In a genealogy of apiologists I might perhaps justly include him in the list of Mr. Root's immediate descendants—at least as his apiarian grandchild.

Mr. E. Vanderwerken was my next-door neighbor when I lived in Stamford, and for several years was generally indifferent to my beekeeping proclivities as well as to some other things of the kind so dear to a naturalist. Indeed, I thought him of all people perhaps the least likely to become a student of the bee, and enthusiastic in the subject, because he and his family so strenuously objected to the appearance of my pets on his side of the fence, and above the sidewalk that they must traverse every day. My apiary was only about fifteen feet from the sidewalk. Indeed, my nearest neighbor's objections became so active that the health officer was sent in to investigate, because they thought there must be some serious trouble at the laboratory, near the apiary, as a mysterious aroma pervaded the entire street. This, as has been previously explained to readers of this magazine, was in the autumn when the delightful perfume of the goldenrod was very strong. Mr. Vanderwerken and the members of his family now regard such objections as jokes, and the other day he telephoned to say that my henhouse is still next door, meaning that the odor of the nectar gathered by the bees from the goldenrod is now at its height.

Some efficient and enthusiastic beekeepers date their interest from earliest childhood; others, in later life, come gradually into the joys of beekeeping; while still others are what one may call a sudden conversion with a baptism of sorrow. My pupil is in the latter class. His apiarian baptism consisted of more than a hundred stings, which, I suppose, accounts for his fierce and fiery interest.

About half way between my home and his (a distance of only a few rods) is an extremely tall tree. One day one of my finest swarms made the air black with swiftly glancing lines that moved slowly around the apiary, and upward and upward, almost to the very top of that tree. There they settled and hung, an alluring, tantalizing attraction, too far up, I decided, for me or any one else on my premises to climb. They remained there for two or three days; and Mr. Vanderwerken, going

to and from his office, stopped every morning, noon, and night, to express his regret that so fine a colony should be lost. The third day was drizzly, rainy, foggy, misty—a generally moist and sticky day. It appears to have been a leisure day with Mr. Vanderwerken, because he came and volunteered to climb that tree if I would supply him with a veil and gloves. I tried to dissuade him, by magnifying the danger, and I assured him that the swarm was not worth the risk; but he seemed to be fascinated by an irresistible impulse to capture that colony. Finally we obtained a long ladder, and I furnished him with veil and gloves. The ladder was wet; the tree was wet; the bees were wet; and to say that they were cross is to speak mildly. When he arrived among the branches, the cynosure of many admiring eyes (because the neighbors had gathered to see the performance, those bees showed fight, and sent out every warrior in the colony to repel the approaching novice. Neither Mr. Vanderwerken nor any other human being could withstand such an onslaught. The veil was wet; it stuck to his face and was useless. He could not even stop to use the ladder, but slid down that tree as hastily as a fireman, awakened by a midnight alarm, slides down the pole without wasting time on the stairs. It was the most successful instance of attack and retreat that I have ever seen. Mr. Vanderwerken, completely covered with bees, fled into the bush, and there fought with hands and leafy branches to drive away the angry insects. The attack was nearly a fatal one for him; and I wonder if he realizes, even with his later expert knowledge of bees, just how dangerous it was. He was obliged to remain in bed for a time, until his suffering was alleviated.

But by this very experience an unexpected result was achieved. He became a beekeeper. It seems as if every sting was a hypodermic dose of enthusiasm, and to this day it remains in his blood. In my experiences with many and various beekeepers I have not known another one so enthusiastic. He began with two or three colonies; he attended conventions; he talked long and constantly about the delights of beekeeping; he buttonholed his friends in the street; he suspended work in his office, and the result is that he now possesses one of the finest apiaries that I have ever had the pleasure to see; yet when I first saw it I did not realize its perfection, because visually it is irregular, and mottled and speckled. There were, at my visit, boxes of high and low degree, all sorts and

sizes, covered with rough roofs on which tar paper was tacked. In every direction was a display of old carpets, cast-off clothing, bedquilts, blankets—every thing. I never saw such a medley. It outrivaled the apiaries of box hives and hollow logs that were common several decades ago, and may now be seen in a few remote farming districts. But this apiary was not chaotic on account of neglect nor of a lack of knowledge. It represented skill of the highest type. Mr. Vanderwerken has silenced Mr. Hutchinson's slogan. Mr. Hutchinson advocated, "Keep more bees." Mr. Vanderwerken says, "Take better care of those you have. Keep them warm and they will work." Within this conglomeration of packing boxes and old bedquilts were the best and finest ten-frame dovetail hives. Mr. Vanderwerken uses the boxes merely as an outer shell within which he puts strips of waste paper secured from a local printing-house. Some of the hives were packed with leaves, but most of them had the paper trimmings which, he assured me, are better than leaves. Many of the hives have three or even four stories, making as high as forty frames, and every frame is loaded to its utmost capacity with pure honey. The twenty-two colonies in his apiary are unquestionably in a finer condition than those in any other that I have ever visited. Although it was a warm day in the first week of September, he was applying the carpets and bedquilts and tar-paper roofings, and various other forms of protection, as liberally as one might expect to see with the thermometer below zero. My pupil has taught me what most of us are slow to learn—that, if we keep the bees warm for the whole twenty-four hours, they will work for twenty-four hours.

In his apiary there is no desertion of super or upper story on cold nights; the bees keep hustling every minute. Then, too, this efficient beekeeper has learned the secret of the survival of the fittest. Only the very best queens are tolerated in his apiary. He has rejected and selected until there he has obtained the highest efficiency in bee work. The combs were beautifully clean, and in perfect condition; and, best of all, the bees were working.

Mr. Vanderwerken takes care of his bees. He has a strong affection for them, and he has so experimented, so gleaned from the experiences of others, and withal put so much thought and labor into his apiary, that I award it the first premium, notwithstanding its somewhat ragged and unattractive appearance. I am glad to ac-

knowledge that my unexpected pupil has become one of the most efficient teachers in the art of honey-producing, and in enthusiastic admiration for the wonderful *Apis mellifica*.

Arcadia, Sound Beach, Ct.

[The two illustrations shown herewith, and the cover picture for this issue, serve to finish the introduction of Mr. Vanderwerken, and to prepare the way for his article which follows.—ED.]

BEEKEEPING IN CONNECTICUT

Honey from Clover of the First Year's Growth

BY E. VANDERWERKEN

Our season just past proved a good one. Goldenrod did not yield as well as it has in some years; but the clover yield was the best we have had for some time. Some have declared that the first year's growth of white clover does not yield nectar. Now, we have had absolutely no clover for two years, and yet this year it yielded the best in a long time. Mr. Coley, who is the most extensive producer in the State, having 350 colonies, says that the clover yield was the best he has seen for years.

Mr. Allen Latham's specialty is sumac, as there are great fields of it around him. This, however, did not yield in our locality as well as usual this year, and I think Mr. Latham says the same of his locality.

I have not done any extracting yet, as I want to get all the aster honey I can away from the bees, as it has not proven to be the best winter food. My colonies are in fine condition. I have twenty-two in the home yard, and six outside. Mr. Bigelow says he can not see how I get such strong colonies. I had one swarm which came out this season which I am afraid I can not get into a ten-frame hive.

For winter I use the sealed super cover or pasteboard over the hive, and over this I put a case packed with dry leaves or thin shavings of paper, which I get at a publishing house for 60 cts. a bale. I leave the entrances wide open. Some make the mistake of closing the entrances, and the hives get cold and damp, and there is too much mold. I have never lost a colony by my method; but sometimes one will show an unusual death rate. When this is the case I wait for a warm day, open the hive, take out three or four combs of honey, and replace it with combs of syrup made as thick as honey in the same number of combs. If the hive is damp I change the combs of bees to a dry one and pack

them again. I have never lost one after such treatment, in spite of the fact that I have been told that, after a colony gets started in this way, it is apt to die before spring. But the bees always show a marked improvement after the change of stores, and come through all right.

A BEE DISEASE RESEMBLING NOSEMA APIS.

A strange disease has appeared among the bees in this State. Sometimes it is accompanied by bee dysentery, but not always. Mr. Coley has had three cases, and has reported others that he saw during his work as foul-brood inspector. He says his own affected colonies died. I had one case, but I did not lose it, as I requeened, and the bees seemed to outgrow the trouble. The bees come out on the alighting-board, surround one bee that seems to be affected, and act as though they wanted to pull it to pieces. The one attacked makes no resistance, even though there may be four or five bees around it. After a time, when it would seem as though the one bee would be nearly killed, the others will stop mauling it about, and it will fly away as though nothing were the matter. Very often the healthy bees will pull out the sick ones and roll them off the alighting-board on to the ground, so that the ground is covered with them. In the one case I had, the queen was a fine-looking one and a good layer. I kept close watch all summer; and, though they have not built up well or stored much honey, I think they will pull through the winter if the trouble does not break out again. If it does, I shall brimstone the bees. We sent a number of the affected bees to Dr. Phillips, and he reported that he could not tell what the trouble was. I have read some of Dr. Zander's articles on *Nosema apis*, and I am of the opinion that *that* is the trouble. I have found traces of it among some of my strong colonies.

If this scourge should become epidemic, foul brood would be in the background so far as loss is concerned. We have foul brood all around us, which is quite enough without any new trouble.

Stamford, Ct.

THE FACTS ABOUT BEEKEEPING IN CENTRAL FLORIDA

BY DR. L. A. SIMMON.

Beekeeping in Florida was written up last year by Mr. E. G. Baldwin; but he wrote of localities where commercial beekeeping is a possibility, and of men who have devoted years to the business, and are princes in the art. It was inspiring

to read his articles, and especially concerning the tupelo belt, where "shiploads of honey go to waste for want of bees to gather it." It should be known, however, that a large area of the State is deprived of the conditions that make beekeeping on a large scale a profitable occupation. That portion of the State known as the "High Land Lake Region," high pine land, and the "Flat Woods" adjoining, produce but few of the honey-bearing plants and trees, and none of those found along the rivers and coast.

The promiscuous summer and fall flowers that grow in great profusion over the wooded lands afford but little honey, but furnish an abundance of pollen. Orange bloom is the chief source of surplus honey. The trees bloom some years as early as February. Last year they did not bloom until in March and April. In order to secure a good crop of orange honey it is necessary to feed the bees in January to stimulate early breeding and have strong colonies when the trees bloom. Orange bloom lasts about two weeks, and, occasionally, is drawn out to three. Gallberry and saw palmetto succeed orange bloom; and if it were not for the fact that the cattle men burn the woods over once a year they would afford considerable honey of a light-amber color and good flavor. But the plants have been so crippled and killed out that this source furnishes barely enough to carry the bees over the summer months. It is my practice to extract the orange honey at the end of the flow. It is then capped over, and ripe. I allow the bees to keep all the honey from all other sources. As a result I have to commence feeding my bees in August, and feed them more or less all fall and winter. Without a knowledge of the impending dearth that begins with the rainy season, which usually sets in about the first of June or July, the bees continue their high-pressure brood-raising during the secretion of gallberry and palmetto honey, which consumes this stock of stores. When it rains every day for two or three weeks, and they begin to discover their predicament, out of honey and none to be found, they begin to retrench by carrying out their larvæ, destroying all eggs, and in every way possible conserving their limited resources. It is *before* this occurs that the vigilant beekeeper must come to their aid. If not, they soon begin to dwindle, and a weak colony of old bees is hard to rejuvenate, and of little value.

Owing to the fact that bees can fly almost every day in the winter months, the

mortality here in the South is much greater than at the North, where they semi-hibernate. As a result, more or less brood-raising is continued all winter provided the bees are furnished the necessary food. Bee-keeping in this part of Florida is a rather difficult problem to the beginner and to most of the native people. As a result, but few bees are kept in a modern way, and those that are kept in "gums" and box hives succumb to the moth-worms and ants in due time. Fortunately we have no foul brood now; and, notwithstanding the fact that bees require feeding a long time if any honey is secured, yet it will pay every owner of an orange-grove to keep a few colonies of bees, and properly care for them, in order to secure the perfect pollination and fertilization of his bloom. The added increase of fruit will more than pay for all the sugar, time, and trouble expended.

Auburndale, Fla.

A WINTER CASE FOR ONE COLONY, WHICH MAY BE TAKEN APART

BY H. FISBECK

Having read the different methods for packing bees for winter in the Sept. 1st issue, I feel as though I should like to give my method in the past and for the future.

After taking out the two outside frames of honey I see that the remaining eight L.

frames contain at least 25 pounds. The empty spaces are filled with pads of newspapers (the outside sheet being a sheet of oiled craft paper) tightly squeezed

in. These pads rest on small sticks on the bottom-board, allowing any water that might accumulate to run under. A $\frac{3}{8}$ -inch board, the same dimensions as the inside of the hive, separates the paper from the combs. A tin spacer is nailed on the bottom of each end of the boards to keep them straight in the hive. I then put on a bee-escape board, leaving out the Porter bee-escape for upward ventilation. When brood-rearing

starts I close up this hole. Closing up this hole in spring, I believe, is a means of supplying bees with water, for it condenses more readily in a sealed hive.

I then place over the hive the winter case, of which I enclose the plans. The case is first bolted (not tight) and set down over the hive. The paper pads like those described before are set down in between the hive and case. The reason I like these pads is because, when spring arrives, there is not a muss made in taking out the packing. Any way, I am a firm believer in paper for keeping in the heat. On top of the cover shavings a foot deep. I

I put on a cushion of then put on the winter-case lid which has a sheet of rubberoid laid on, lapping over. Then a strip of tar paper is wrapped around the four sides of the case, being lapped in the front. The ends of the bolts are forced through the paper, and the washers and nuts tightened. This tightening makes the packing one solid mass of paper. I then push in a row of thumb-tacks around the top and bottom of the tar paper.

The paper pads are made by folding an ordinary newspaper in half and placing one paper inside another, etc. That necessitates making each inside paper

smaller than the one it is placed in. They are $1\frac{1}{2}$ and $1\frac{3}{4}$ inches thick. These pads are saved for the next winter, etc.

The principal advantage of this case is its cheapness, and its being easily stored away in the summer. This case is large enough in this latitude. My smallest colony wintered perfectly through the last very severe season. Colonies can be easily in-

spected by lifting off the lid and taking out the cushion of shavings and hive cover. St. Louis, Mo.

A LOW TEMPERATURE IN BEE-CELLARS

Not Much Harm Done if Air is very Dry

BY ELMER HUTCHINSON

On page 648, Oct. 15, the editor takes exceptions to my statement that bees can be safely wintered in a cellar with a long-continued temperature as low as 34 degrees. I know that is the generally accepted opinion. Mr. James Heddon once wrote that cold in a cellar is a giant. But I added several provisos; first, there must be strong colonies of healthy bees; second, they must be well supplied with good stores; and right here is where I believe a good many fall down in wintering bees. They don't make sure that the colonies have stores enough. Where the bees are short they seemingly consume more than if they had plenty; and that very fact has a tendency to keep them uneasy. Then if the combs have at least 40 lbs. of good honey or thick sugar syrup in them they get warmed through by the bees, and are a big help in keeping an even temperature inside the hive. I may say here that I have fed more than 5000 lbs. of sugar this fall to put my bees in that desirable condition for winter.

Like Dr. C. C. Miller, I believe one of the main essentials is pure air, and plenty of it. I have always noticed that, when the air gets foul in a bee-cellar, although all the other conditions may be perfect, the bees invariably become uneasy and begin to roar. The cellar I wintered those bees in last winter was an old one that had not been used for several winters, and was somewhat out of repair, so that there was plenty of fresh air. That was one reason it was so cold. I had intended to fix it up a little after the bees were in; but they seemed to be wintering so well that I let it go as an experiment. The thermometer was a tested instrument, so there could be no question about its being right.

Now, don't think that I advise every one to let the temperature of the bee-cellar drop to 34 and stay there; for in the majority of cases I know that it would make trouble. There would be some necessary condition lacking that would probably result in the loss of the most of the bees. I know that, when I lived further south in the State, I never could let the temperature go below 40 degrees without having the bees begin to roar; and if the cellar was not warmed up at once there was a big loss of bees

before spring. I suspect that what causes the difference is the dryness of our air here. In this locality I can be out of doors when the temperature is 20 below zero, and my body never gets cold; and I never wear an overcoat unless I am driving. When I go back to the southern part of the State in the winter, even with a heavy overcoat, I can be out of doors but a short time before I am chilled through and my teeth chatter, even if it is only a few degrees below freezing. It is all caused by the dampness of the air there, and I think that is one reason why the bees can stand more cold here in the cellar than they can further south. Therefore if the temperature in the bee-cellar is lower than 40 degrees the air *must* be very dry.

Pioneer, Mich.

LIME OVER A BROOD CHAMBER IN WINTER

Its Use Advised Back in 1880

BY ARTHUR C. MILLER

In GLEANINGS for December 1, 1880, p. 579, is an article headed "A New Idea in 'Wintering.'" It is almost or quite worth reprinting. It fits in with an article in the Sept. 1st issue. It is interesting in suggesting fused calcium chloride—a material since used for the purpose by Mr. Latham and others.

[The following is the article referred to:—Ed.]

A NEW IDEA IN WINTERING.

This will be a hard winter on bees in most parts of the country, on account of lack of good stores, and mostly old bees—a poor prospect certainly. We must help the little fellows, or make up our mind to lose them. Last winter I kept ten stocks warm, dry, and in good health by chemical means; *i. e.*, by generous use of quicklime. My other stocks had the dysentery, and every one of the chaff hives was mildewed and wet, in spite of three dryings during the winter; while the ten cushions used on the hives with lime were as dry and clean as when first made. No one will believe the amount of water quicklime takes up by chemical affinity unless he try the experiment for himself; therefore, take about one quart of it in a basin, and $\frac{1}{2}$ pint of water, which pour slowly on the lime, stirring well all the time during the slaking; and if the lime was properly made you will have a perfectly dry powder, still capable of absorbing more water before becoming damp. The action of the lime is threefold:

1. It absorbs moisture;
2. It absorbs carbon dioxide (carbonic acid);
3. It gives out a large amount of heat.

This it does slowly, and in exact proportion as it absorbs the breath of the bees; *i. e.*, much moisture, rapid chemical action, much heat. What is still more strange, this is dry heat, not moist.

This absorbing action is so slow, and the amount of heat so small that nothing but scientific instruments (hygrometer and thermometer) and the bees can appreciate the meaning of a *constant, mild, dry, pure atmosphere*. What is the use of making the bees use up their honey, worth 15 cts. per lb., to develop the requisite heat to keep themselves alive, when it can be done with lime, worth less than one cent per pound, and which is almost as valuable *after* this slaking as before? Don't believe me when I say not one of the ten hives above mentioned

used over 15 lbs. of honey (all they had) in wintering out of doors, even if it was a mild winter, for I can hardly realize it myself, even when I see the figures in my yard-book now before me.

When you try the experiment of slaking the lime, notice the heat development, but not with your finger (unless for a cartoon). I used the lime in a feeder *a la* Van Deusen, made flat, and laid broadside next the bees under a cushion. This was troublesome, requiring frequent refilling. I will use, this winter, on my weak stocks, a box made like your chaff-cushion division-board, and to hold about half a peck of lime.

Chloride of calcium (calcined) will absorb much more water than lime, and I expect much from it for these same purposes; but it will have to be contained in a water-proof vessel, as it is one of the most deliquescent substances I know of. Absence of actual experiments is the only reason that prevents me from recommending this substance to the careful beekeeper, although I am certain it would be a success. C. LOVER.

Reisterstown, Md., Oct. 18, 1880.

[In case of a weak colony with stores of poor quality, we can see that the lime might be of advantage in preventing dysentery. Or it might prove beneficial in any instance where conditions are so unfavorable as to cause dysentery. When all conditions are favorable we do not believe that the lime would pay for itself, for the amount of heat generated would be so infinitesimal at any given time that it would have no practical value.—Ed.]

BEES WORK ON DEAD-RIPE MUSHY BERRIES ONLY

BY WILLIAM BELSHAW

There is some question as to whether bees will trouble berries, p. 540, Sept. 1. I can safely say they will suck the ripe juices from blackberries. I purposely went to my blackberry patch, and saw them busy doing it. But what if they do? There are berries there enough and to spare—bushes just loaded down with berries in all stages; some just formed, and others in all shades of green, red, and black. Among the black alone there are the solid black such as would do for long shipment and for jelly; others a little riper that would do for immediate sale for making sauce and for canning; and some mushy-ripe ones that burst in the fingers while picking, and that are, consequently, useless. Now, the bees work on these mushy-ripe ones. They do not interfere with any of the others, therefore they are taking fruit that is beyond value for food.

This work of the bees is welcome; for since they take the berries on the verge of decay, they save to some extent the rest of the berries from contamination of the germs of decay. For my part I prefer to let the bees remove the dead-ripe fruit that has passed beyond the point of usefulness. Snohomish, Wash.

FURTHER NOTES ON HOW THE CORBICULA, OR POLLEN-BASKET, IS LOADED WITH POLLEN

BY F. W. L. SLADEN, F. E. S.

On page 172,* March 15, the writer advanced the theory that the pollen is loaded in the corbicula, or pollen-basket, situated on the outer side of the tibia of the hind leg of the worker honeybee, and of the queen and worker bumblebee, by being combed into a receiver situated on the end of the tibia and then forced up into the corbicula by a projection at the base of the metatarsus called the auricle. Three reasons for the support of the theory were given: first, the structure of the parts; second, an experiment made with a dead queen bumblebee's leg in which the auricle was made to force pollen into the corbicula artificially; third, the rubbing-together, exclusively in a longitudinal direction, of the hind metatarsi, observed in a worker honeybee collecting pollen from *Eranthis hiemalis*.

Since that article was written the flowers have opened and have offered many opportunities for investigating pollen-collecting.

On a fine morning, some weeks ago, I stopped the entrance of one of my hives with grass, and in a few minutes about a hundred pollen-laden bees had gathered there. Among them were two or three whose loads consisted of pollen of two colors. These I caught and dropped into my killing-bottle.

Going to other hives, I soon secured many bees with parti-colored loads. A careful examination of these indoors not only confirmed the above theory but showed exactly how the pellet of pollen grows. The accompanying drawing shows the loaded right leg of one of the bees that were caught. The pellet consisted of white pollen, with the exception of a small quantity of orange pollen, evidently added afterward, for the metatarsal brushes contained orange grains. The orange pollen had been forced in as a wedge between the white pollen and the corbicula, the wedge having been driven in at the corner of the corbicula that comes into contact with the auricle. The new pollen could not have gotten into the corbicula by being scraped on the upper edge of the corbicula, as Cheshire supposed, nor could it have been plastered on to the pellet with the metatarsus of the middle leg, which is the way that propolis is loaded in the corbicula (see my article, page 335, June 1), for the or-

* See also my article in the *British Bee Journal*, Dec. 14, 1911.

Right hind leg of worker bee laden with pollen of two colors, white and orange. The close dots indicate the orange color, and the remote dots pale orange color; the clear portions are white.

ange pollen was situated where no outward application could place it. The repeated forcing-up of the pollen by the auricle into the corbicula often causes the pellet to buckle about the middle, as shown in the drawing. Notice, too, the tinge of orange—rather dingy, and only skin deep—on the outer side of the pellet. This, I believe, is the footmark of the metatarsus of the middle leg, which is used to pat down and to shape the pellet as it rises and swells (see page 336, June 1). One can now understand the function of the fringe of stiff hairs around the pollen—the so-called basket-hairs. They guide and shape the swelling mass. Those on the upper edge of the tibia stand up straight and allow the pollen here to rise straight up too. But the hairs on the lower edge curve outward and upward, and they make the swelling lump of pollen do the same.

It is interesting to note that the teeth of the comb situated on the end of the tibia (see illustration, page 173, March 15), that are used to comb the pollen out of the metatarsal brush (of the opposite leg) have their tips about the same distance apart as most of the bristles in the metatarsal brush, namely, about 1-25 of a millimeter.

A suitable name for the receiver for pol-

len at the end of the tibia is the *excipula* (Latin, receptacle); and for the entrance to the corbicula, the *limen* (Latin, threshold).

The clothing on the *limen*, the function of which is evidently to form a surface for the first contributions of pollen to cling to, varies in different species of bees, and makes an interesting study. In most species of bumblebees the *limen* bears a dense coat of moss-like fluff, beyond which stand about three long stout hairs widely separated from one another; but in some species, notably *Bombus violaceus*, a native of Brazil, the fluff is bordered on the inside with fine hairs; and in *B. confusus*, a central-European species, the fluff is very long and dense, and the long stout hairs are usually reduced to one stunted example. In the honeybee the *limen* looks bare when viewed from above; but if it is viewed endwise, and suitably illuminated, it will be found to be clothed with fine fairly long fluff.

Some way, inside the entrance to the corbicula, near its upper margin, there is a single long hair (not shown in the drawing on page 173). I have examined several specimens, and have found this hair present on each of them.

Ripple Court, Dover, Eng.

Beekeeping in the Southwest—Continued from page 720

of them are shipped by the producers to hundreds of towns and smaller cities, I saw no real reason why these same packages should not be handled by the large city grocers.

The packages referred to and adopted as standard in Texas for both bulk comb and extracted honey are the two 60-lb. square cans to a case; ten 12-pound friction pails to a case; ten 6-pound and twenty 3-pound friction-top pails to the case. Many carloads of these are used annually—the ten 12-pound and ten 6-pound sizes being the most popular.

My investigations revealed, however, that the richer class of people of the city do not pay so much attention to the matter of cheapness in buying as to the appearance of the article.

GLASS PACKAGES FOR THE FANCY TRADE.

I found, therefore, that glass bottles and jars please these well-to-do people. I further ascertained that it is almost impossible for these stores to sell a larger package of honey than a 50-cent size, and that a 30 or 35 cent size is the best seller. My own observation and experience in disposing of honey at fairs has revealed this same thing. It is true that some persons will buy larger packages at a fair; but it must be remembered that, as a usual thing, these purchasers are not of the better-to-do class.

TIN PACKAGES FOR THE MASSES.

As soon as we leave the strictly fancy city-trade grocers we find those who have the average-to-do persons for their customers. In these stores it is no trick to sell a larger package at a time, provided it is cheap enough. The most economical package then is the tin pail. But even in case of these, only the smaller sizes, 3 and 6 pound pails, are in most demand. In the general stores, however, on the very outskirts of the large city, or in the general-merchandise stores of all the smaller cities and towns, the larger packages are most in demand. Here the country trade predominates, and the well-to-farmer purchases his honey in the 12-pound or gallon pail, just as he buys his dollar's worth of sugar and coffee. These stores are the ones which usually prefer to order direct from the producer in case lots, thereby saving the middleman's profits.

WHERE THE 60-LB. CANS COME IN.

It is in these stores, also, that much honey is still sold out by weight from the large square 60-lb. cans, the purchaser usually furnishing the vessel. Of course many 60-pound cans are also bought by a single family. These purchases are rather few

as compared to the 12 and 6 pound-package sales.

It might be well to state that the 60-pound can is not as popular as it used to be, especially for bulk comb honey. This is according to my experience at least. It may have been brought about by the fact, however, that we have made the 12 and 20 pound pails more of a specialty. At the same time, though we quote the prices of each kind in our lists, yet the orders received show a decided favor for the above-mentioned pails.

From the beekeeper's standpoint there is an advantage in furnishing these sizes over the 60-pound cans. While the pails cost a little more per case, it does not require as much comb honey for packing them. As the comb honey is the most expensive part of the contents, this is an item of importance. It must not be forgotten, either, that the price for the 12-pound pails, by the case, is $\frac{1}{2}$ cent per pound more than the 60-pound cans, and 1 cent more for the 6-pound pails. On a large crop, amounting to several hundred cases, the extra profit amounts to a good many dollars. It is enough to be worth considering by the beekeeper. I investigated this especially, since a number of beekeepers have argued this point, favoring the 60-pound cans rather than smaller sizes.

THE SUMMING-UP.

The conclusion derived is that one must study his markets closely; for that which sells in one place very readily may not in another. As a result of my investigation I find that I must furnish my choice product in fancy glass to the city fancy retail grocer, while the market for the more economical package is found in the suburban stores and those of the smaller cities and towns. The wealthy farmer is the best customer for a larger quantity at a more moderate price. And here is one point in this connection which I wish every beekeeper would think about more seriously. That is, to make a greater effort for a more general and wider distribution of honey. Instead of glutting the large cities, it is of the utmost importance to fill the wants of the general masses who are to be found nearer the towns and country places, and on the farms where no bees are kept.

I do not wish to be understood as being against furnishing the city markets with their share of honey; but I do raise an objection against the too common practice of looking toward these markets and neglecting the market nearer home.

Heads of Grain from Different Fields

Are Redwood Hives More Immune to Bee Disease than Hives of Pine?

An extensive beekeeper of Saltriver Valley uses redwood exclusively for the hives in all of his apiaries. He buys a great many colonies of bees throughout the valley, but they must be in hives made of redwood or he passes them by.

This man claimed bees are free from diseases when occupying the redwood hive.

If I am not mistaken, the redwood is a species of cedar or fir family; and I guess the most of us know what a panic the oil of cedar creates among insects when applied to them, that bother us in our houses. My bees are mostly in the redwood hive, unpainted. The oil in the paint destroys the effect of the oil of cedar in the redwood lumber. Bees could not be healthier than mine are.

Phoenix, Ariz., Oct. 25. L. M. BROWN.

[Some years ago we traveled extensively through the redwood districts, or, rather, where the redwood hives were used, and our recollection is that foul brood was just as common in hives made of that as of pine or any other material. While cedar chests are supposed to keep out moths that will eat into fur or woollen goods, it should be understood that the moths themselves are very different in general characteristics from the microbes that cause foul brood, both American and European. Your friend, the extensive beekeeper, must be entirely mistaken in believing that redwood has any thing to do with keeping out the bacteria of bee diseases. If there were any thing in his idea, the Bureau of Entomology would have known it long ago.—ED.]

A Swarm Hangs on a Limb Nearly Two Months without Building Comb

On September 11, six weeks ago to-day, some boys called my attention to a swarm of bees clustered on the limb of a large white-oak tree, about fifty feet from the ground. As the tree stands in front of my house it has been easy to watch them. The swarm was a large one. No one is positive when the bees settled there, although workmen in the fields near my house say that they saw a swarm pass and go into the grove the last of July, and they tried to find them but failed. To my knowledge this swarm has been there six weeks, and for the past four weeks it has been gradually growing smaller, due to clumps of bees dropping off to the ground from weakness, particularly on cool mornings, until this morning the cluster was not larger than a man's fist. Since I first noticed the cluster it has moved gradually about six feet further out on the limb. Is it not very unusual for a swarm to hang like this until the bees starve?

Later.—The last of the swarm dropped from the limb on the 20th or 21st of this month, and all died on the ground beneath the limb. There was no comb built anywhere on the limb.

Blackstone, Va., Oct. 16. N. S. MAYO.

[It is unusual that a swarm should hang on a limb so long in the open without making at least some attempt to build comb. There have been reports of outdoor colonies; but in every instance that we have known, the bees have built combs on the limb and made an attempt at establishing conditions as nearly as possible resembling those inside of a hive; but even such outdoor colonies usually dwindle away to almost nothing at the approach of cold weather.—ED.]

Are Carniolans Prone to Supersede their Queen?

In one of Dr. Miller's Straws, page 612, Oct. 1, he quotes Editor Gerstung as saying that bees generally supersede their queens during the spring. Are these bees Carniolans? My experience with these bees is that they are invariably well ahead in numbers in the spring, and during fruit-bloom supersede, swarming with the first-hatched queen. I have had this happen several times, and with three different strains of bees. I attribute this to the exceedingly rapid way these bees build up, the queens being worn out early. Or is it due to their being naturally short-lived? I am inclined to think that the excessive swarming experienced is due to this superseding. In this country they have the reputation of being excessive brood-rearers—that is to say, they

keep on rearing brood in quantity, right through the honey-flow, using up the greater part of the income. Their crosses, particularly with blacks, are invariably vicious, and on these counts I have decided to clear them out.

I am unable to understand how it is that, with you, blacks have such a bad name. Probably they are not quite the same variety as ours. I am convinced that, taking one season with another, blacks of a good strain are the best for us, and particularly is this so when sections are run for. I am free to admit that some Italians I have had are first rate, for extracted. I shall be glad to hear whether your experience with Carniolans coincides with mine.

H. H. BROOK.

13 Westgate Hall, Altrincham, England, Oct. 12.

[Your experience with Carniolans is very much the same as ours. They are excessive swarmers, in season and out of season; and since you mention it, part of this excess of swarming may be due to the tendency of the bees to supersede their queens. As you say, they are heavy breeders in the spring, and they breed heavily when the honey-flow is on. Naturally enough, this would tend to cause supersede a little earlier than it would with the Italians.

We would be pleased to get reports from those who have tried Carniolans pretty extensively; because the more thoroughly we understand their peculiar habits, the better able we shall be to hold in check some of these undesirable tendencies.

With regard to black bees, from reports we have received we are convinced that the English strain of these bees is much superior to those in America.—ED.]

A Protest Against Mending Broken Comb Honey with Paraffine

I note the reference to the plan of mending the cappings with warm paraffine, p. 617, Oct. 1. After looking in vain for a footnote or comment on the above article, I can not but believe that the sin of omission is as great as if not greater than the one of commission. One of the worst of the comb-honey canards is the general belief by the public that paraffine is mixed with honey, or, rather, is manufactured into comb, and I am surprised that you would permit any one to advocate daubing up comb honey with it, without a word of caution on your part.

Dewey, Okla.

M. H. HILL.

[The amount of paraffine used would be so very small that there certainly could be no objection to it, providing one could afford to give the time to patch up here and there a broken cell. Moreover, paraffine melts at a lower temperature than beeswax, and this one fact would make it possible to make repairs with it when it would not be practicable to use bleached beeswax. Hot beeswax applied to the cappings of ordinary comb would, of course, melt the other beeswax with which it comes in contact; whereas a hot paraffine, relatively somewhat cooler, would not affect the beeswax.

While we most strenuously object to making foundation out of paraffine or using it in any large way in the bee business we can not see that there is any objection to its use in the manner related by our correspondent on page 617, Oct. 1. As a matter of fact, it will be impracticable to use paraffine to make repairs on comb, for the simple reason that the time consumed in applying it would more than offset any possible increase in price that the section would receive from the repair. We do not think our correspondent needs to worry over the thing, for the process can never be a commercial possibility.—ED.]

New State Beekeepers' Organization of Massachusetts

On September 14, at the State Mutual Restaurant, Worcester, Mass., Mr. J. B. Levens, of Malden; O. F. Fuller, Blackstone; J. L. Byard, Marlboro; A. A. Byard, West Chesterfield, N. H.; Arthur Monroe, Spencer; and Dr. B. N. Gates, of Amherst, met at an informal dinner for the purpose of discussing the advisability and method of forming a State beekeepers' association for Massachusetts. The invitation to this meeting was extended by Dr. Burton N. Gates, of the Massachusetts Agricultural

College, acting as Secretary of the Hampshire, Hampden, and Franklin Beekeepers' Association, who voted last spring to further the organization of a State society in which there should be representation and co-ordination of the various local societies of the State.

The sense of those present in Worcester was so unanimously in favor of the movement that it was voted to form an association to be known as the State Beekeepers' Association of Massachusetts. Provisional officers were elected by unanimous vote as follows: President, John L. Byard; Vice-president, J. B. Levens; Secretary-treasurer, Burton N. Gates.

The constitution and by-laws were discussed, a memorandum drawn up and authorized, and submitted to a committee composed of presidents and others of the several societies now existing. It was further voted to hold the first annual meeting of the organization on the second Saturday in January, 1913, as a joint meeting with the Worcester County Beekeepers' Association, in Worcester. It was furthermore voted to announce this organization through the courtesy of GLEANINGS.

Briefly, the organization is designed as a medium of union and co-ordination of the various loyal societies in Massachusetts for the purpose of devising and promoting measures that are of general interest to the beekeepers of the State, and to encourage the organization of local co-operation in the several districts of the State, as well as to promote and impress upon the public the importance and value of the beekeeping industry.

Since this organization is distinctly in the interest of individual beekeepers of the State, the Secretary solicits your suggestions, and will gladly correspond with those interested.

BURTON N. GATES.
Amherst, Mass., September 25.

Lining the Wire Cloth of Queen-cages

Some time ago I wrote suggesting that the wire netting on the queen-cages be covered so that the bees might not come in contact with it. The reason for my suggestion was this: I found that, if one cage of bees arrived dead, the whole lot were dead, and *vice versa*. I argued that the same hand that put in one cage put in all, and all in the same position. Whatever position one assumed they all assumed. I found that, if a lot came alive, they came in fine order. It seemed to me probable that this difference depended on whether the wire netting formed the floor or the roof on the voyage. If the former it became coated with bee food, and the rust in turn killed the bees in their cleaning-up. The last lot you sent me came in excellent order—all five—and I observed you had adopted my suggestion, and covered the wire. It is the suggestion of ignorance again. I may mention that the exit hole and three tiny holes in the side were all the ventilation the bees had. Under an adverse situation would this suffice? The bees had just begun to eat down the cover of wire, but this was quite fresh. Every cage had about half of one side eaten away.

When removing a super of honey I found a single queen cell sealed with royal jelly and live larvae. There was not a single egg nor larva otherwise. The queen-excluder was in good order, and the queen was in the brood-chamber. In this island bees seem to yearn for the presence of a queen above, and will readily raise queens there. I think this is convincing proof that bees will transfer eggs.

W. G. HUTCHINSON.

St. Joseph Rectory, Barbadoes, Oct. 7.

[We can see no reason why wire cloth, whether it be next to the little bunch of bees in a mailing cage, or protected, so it does not come in contact with them, would have any effect one way or the other. The very fact that you notice that, whenever the bees in one cage are all right, the bees in the other cages are also, points strongly to another cause for the death of the bees and queens. Sometimes the contents of mail-sacks are fumigated to prevent the spread of disease to human beings. If there are packages of bees in those sacks this fumigation, of course, kills the occupants of *all* the cages alike. We think, therefore, it is safe to conclude that, whenever the bees in *all* the cages are dead, the cause is not due to the wire cloth, construction of the cage, nor to the food, but to the fumigation. If, however, one or two cages of bees are alive, and the rest dead, the cause is, clearly

enough, not fumigation, but some other condition. We can not, therefore, believe that black wire cloth, such as is always used in queen-cages, could have any effect one way or the other. There is no reason why it should. But *green* wire cloth, on account of the arsenic in the paint, might do harm.—Ed.]

Do Carniolans Resist European Foul Brood More Readily than Italians?

I should like very much to learn to what extent Carniolans resist European foul brood. What has been the experience of those who have had an opportunity to compare their resistive qualities with those of the Italians? An acquaintance of mine, Mr. E. Baker, of Los Angeles, has tried Carniolans, he says, for two seasons, side by side with golden and leather-colored Italians, and in his opinion the Carniolans are twice as resistant to European foul brood as are the Italians. He spoke of a number of instances where he introduced Carniolan queens into Italian colonies that were badly affected with the disease, and in every case they effected a permanent cure. At least he says the disease has thus far failed to reappear.

Now, this is a subject upon which too much light can not be shed. It is the commonly accepted belief that Italians are the most resistant race of bees to European foul brood; but let's hear what those who have tried both races have to say.

Artesia, Cal., Oct. 9.

H. PERKINS.

[One or two reports have shown that Carniolans, like some strains of Italians, seem to be much better able to resist European foul brood than ordinary black bees. Other reports indicate they are no better. Reports so far received seem to show that a good strain of Italians will resist European foul brood much better than any of the black races.

We ourselves have had no opportunity to make any observations along this line. Let us hear from those who have had personal experience with both races during a siege of disease.—Ed.]

Dipping Queens in Water in Order to Clip the Wings More Easily

I have had some little difficulty in clipping queens, although I have tried several different kinds of tools. Mr. Y. Susuki, of Wakayama, told me of the following plan: He puts the queen into a cup of water so that she will spread her wings in the attempt to fly, in which position they may be easily clipped with scissors.

MASAMI YOSHINURA.

Shimomakuwa Mura, Motosugum, Gifuken, Japan.

[While we have not tried the plan of putting the queen into water, we feel sure that the plan recommended in the A B C and X Y Z of Bee Culture is better, for there is no danger at all if the queen is held in the manner described, the wings naturally lying in such a position that they are easily clipped without danger of clipping a leg, or injuring her otherwise. The best way is to practice on drones until one has no trouble in clipping the wings quickly. The task is then a very easy one.—Ed.]

Sections of Dark Honey for Winter Stores

Relative to the article, "The Wintering Problem," p. 630, Oct. 1, perhaps my way of preparing bees would be of some interest or benefit to those who winter on summer stands in Danzenbaker hives. I take out of the supers all inside fixtures and lay on the brood-frames 11 sections of dark honey, as I usually have a flow of dark honey in the fall. Over this I spread a burlap sack, and put on the cover. I have not lost a colony out of fifty since 1908.

J. A. KREIGHBAUM.

Hartville, Ohio, October 15.

Death of W. A. McPhail

W. A. McPhail departed this life Sept. 30, 1912, in his 81st year. He had been a subscriber to GLEANINGS since 1877. He started beekeeping in Atascosa in 1878, and closed out his business in 1905 on account of failing health. He was one of the pioneer beekeepers of Atascosa County, and owned 200 colonies at one time. His largest crop was 14,000 lbs. of extracted honey.

Floresville, Tex.

MRS. W. A. McPHAIL.

Our Homes

A. L. ROOT

Her ways are ways of pleasantness, and all her paths are peace.—PROV. 3:17.

The house of the strange woman is the way to hell, going down to the chambers of death.—PROV. 7:27.

Dear friends, you may be surprised to see the beautiful text at the head of this talk linked together, as it were, with the one just below it; and, in fact, I have placed them side by side purposely in order that both of them may shine out by the strong contrast. *Wisdom's* "ways" are contrasted with the ways of wickedness and sin. It is like the whiteness of snow when it is in contact with the blackness of soot. My talk is to be mainly under the head of the second text—life and death contrasted—spiritual life and spiritual death. Below is a clipping from the *Cleveland Plain Dealer*. Read it:

Cleveland morally is better off than it has been for ten years, police announced last night.

This is the result of the most energetic "clean-up" that police in that time have conducted of so-called grill rooms, doubtful rooming houses, questionable dance halls, and other places in what was referred to in the Baptist vice report as the "flat district."

Lieut. Thomas Martinec, placed by Chief Kohler in charge of a special vice squad of thirty-five plain-clothes men about two months ago, when the crusade was taken up, yesterday said more than 500 undesirable men and women, *mostly women*, have been sent out of town in that period.

Hundreds of girls, young women, and men nightly have been taken unceremoniously out of so-called grill rooms, rooming houses, and various other places by the special vice detail, placed in patrol wagons, and taken before Lieut. Martinec. Their names and addresses have been taken, and they have been either "golden ruled" and warned not to be caught again, or ordered out of the city.

"We have seen that every one of the 500, and more ordered out of town actually did go," declared Lieut. Martinec. "In every single case a plain-clothes man went along to see that they gathered under their effects, bought a railroad ticket, and were aboard their trains."

The past week marked the culmination of the "clean up" that has rid Cleveland of so many undesirables. Police Inspector Rowe last night declared himself well satisfied with Cleveland's present moral tone, adding that the city is cleaner than it has been in years.

Just how much longer the plain-clothes vice squad will be kept at work Inspector Rowe said he did not know. It may be only another week, it may be all winter, he said. He said, however, that the work has been accomplished much more thoroughly than it ever has been before.

There are about fifty of these so-called grill rooms, Lieut. Martinec said, that are little more than saloons with a back room furnished with drinking tables where women who have been the object of the special "clean-up" have *plied their trade*. As the result of police activity, patronage at these places has fallen to next to nothing, investigation has shown.

Conditions in this section were at their worst when the Baptist vice commission made its report a year ago. At the time, the report said an investigation by women detectives of 1200 working-girls, receiving small wages, disclosed that "out of the total number of cases gone into it was found that about 200 girls were living in rented rooms in the downtown section, and soliciting in downtown grill rooms, on the streets, and in the dance halls."

One case, worse than the others, was that of a girl 14 years of age, brought in with a man much

her senior. The girl was turned over to juvenile court. The man was sent to the workhouse.

The above long editorial, of which I have taken only a few fragments, was written or dictated with the idea that it was encouraging news. Well, in some respects it is encouraging. I am glad, and, in fact, I rejoice to know that the officers of the law have done *something*; but, oh dear me! what an *admission* it is in regard to the iniquity going on in great cities! The italics in the above are my own. Notice first there were 500 "undesirables" all together; and then look at that comment—"mostly women."

The whole State of Ohio has just been discussing how much better morals we should have if women were allowed to vote; and the whole wide world, or at least a part of it, is in the habit of looking up to the women as the saints or as "guardian angels" compared with the rest of mankind; and this is right and proper and true. That expression, "grill room," has always jarred on my sensibilities; and may be I am stupid, or behind the times, when I confess that I had until now only a dim idea of what a grill room is. The above extract gives the definition. It is a saloon open at night, and especially nights and Sundays as well, with a back room where lewd women "ply their trade." The city acknowledges there were about *fifty* such places in Cleveland.

By the way, let us pause a little right here. When that Baptist commission a year ago demanded that the saloons should close nights and Sundays according to law, the chief of police of the city replied sneeringly that "there would not be prisons enough in the whole city to hold the culprits." That was given as a reason for not enforcing the law. By the way, Mr. Rockefeller donated a very large sum of money to eradicate the hook-worm in the South. This was a praiseworthy object; but what is *hook-worm* compared with the grill rooms of our cities—rooms where they entice (and perhaps purchase for money) girls fourteen years of age or less? And this is going on right here in this land of the free and the home of the brave—right in our own fair State of Ohio—the State that we have proudly boasted was centrally, geographically, and in other ways, in the front rank in regard to morals. May God help us. We can fight smallpox, yellow fever, diphtheria, and all such things, without let or hindrance; but when it comes to petitioning our

government, not only to give time and money, but to stop and even *consider* the death and ruin that come from the saloons or the beer traffic, Uncle Sam puts his hands in his pockets and stands mum. Taft, Roosevelt, Wilson, none of them dare make mention nor even *whisper* in regard to the rum traffic. The cigarette business is following in close wake, because there is *money* in it—yes, paltry dirty nickels—mainly nickels—in the business of selling cigarettes to children or giving them to children, to create an appetite. Our great Uncle Sam stands with his arms folded or looks the other way. Of course there is *some* legislation against cigarettes.

This same *Plain Dealer* has made mention many times of the three-cent dance halls, and has spoken encouragingly of having more such dance halls established, even under the auspices of the city itself; but the clipping says that heretofore, if not just now, these lost girls were using the dance halls as a place for "soliciting." Have they never read that closing verse of the seventh chapter of Proverbs, "Her house is the way to hell, going down to the chambers of death"?

You will notice in the above the expression "golden ruled" is used several times. Do you know what "golden ruling" means? I will tell you. It means letting criminals go scot free after they give some sort of feeble promise to "be good." Some time ago the Anti-saloon League, after the expenditure of considerable time and money, caught three men red-handed selling liquor in dry territory. They were both proved guilty, fined, and sentenced to imprisonment. While they were in prison a golden-rule officer reviewed the case and turned them loose to go back to their regular business. The only excuse he gave was that the punishment was "excessive." I suppose golden ruling means as a rule to say to a criminal, after he is caught, something like this:

"My friend, the golden rule admonishes us to do unto others as we would have others do unto us. Therefore I set you free."

What sort of philosophy is that? And it is, without question, the sort of philosophy that accounts for the terrible *increase* in crime and wickedness throughout our land. I said in starting out that we might rejoice that *something* had been done; but Superintendent Rutledge, of the Anti-saloon League in Cleveland, tells us the above reports are very much exaggerated, although he rejoices, as I said, that something has been done. He further reports to the *Cleveland Press* the fact that mem-

bers of the Chamber of Commerce own property in the tenderloin districts is one great reason why this hellish traffic has been allowed to go on unrebuked and unpunished.

Let us now consider another phase of this "clean-up." These vile people, men and women, have only been sent "out of town." They have not been punished by fine or imprisonment. They are simply admonished to go somewhere *else* to ply their trade. To make sure they really *did* go somewhere else, these brave policemen saw them on the train and witnessed that they bought railroad tickets. Now, seriously, how much better off is humanity in general, take it the world over, when criminals are made to go somewhere else? When so many of our Southern States went dry the liquor-dealers all piled into Jacksonville, Florida; and if you will read a Jacksonville paper (advertisements especially) you will know something about the results. Our Prohibition friends have objected to our local-option work because we many times, at least, have succeeded only in making the rumseller move over into another county. Several times it has transpired that he was simply obliged to rent a room on the other side of the street, and go on as before. The above is certainly a bad feature of local option. But the Anti-saloon League usually gets right over into the neighboring county, so to speak, if it happens to be wet, and proceeds to make that county dry also. Now, if this crusade against vice, which I believe was originated by the Baptist Brotherhood, proposes to wage war, not only in Cleveland but in every other large city, that is all right. May God help us in our efforts to wind up the saloon and the grill room, and put a stop to that awful traffic whose "house is the way to hell, going down to the chambers of death."

THE PRESIDENTIAL BEE.

When the presidential bee
Goes a wand'r'in' far and free,
A-seekin' various persons for their gore,
He's the bug of all to fear,
For if once he gets yer ear
You never ain't no good for nothing more.
We've the skeeter boiled in oil,
And to swat each fly we toil;
Germs and microbes—sure,
We've got them on the run;
But the presidential pest—
Sits a-hatchin' on its nest—
What an awful brood we'll have
When he gets done!
Each 'lection year he'd hum,
And we thought 'twas goin' some;
But now he never stops a-raisin' Cain;
We'll just force him to vamoose
(For he ain't no sort of use),
Then we'll settle down to bein' safe and sane.
—C. B. W.

High-pressure Gardening

"THE ELLIS POTATO SYSTEM;" SEE SPECIAL NOTICES, OCT. 1.

For the \$3.00 I sent, I received some instructions about growing potatoes. The instructions, however, although they cost more than the \$2.00 potato-book and our own combined, I do not think can be worth any thing near what those two up-to-date books ought to be worth to any potato-grower. As it is getting to be quite the *fashion* to have some "system" for sale, I want to go into this a little more minutely.

You will notice that this system promises to tell you how to grow big crops of potatoes—600 bushels per acre, for instance. Well, I will tell you what I got by way of instruction for raising this big crop. First, it is copied from the book "Garden Yard," by Bolton Hall. In fact, Ellis acknowledges that he copied it. It was poorly copied with a mimeograph, or some machine for taking many copies from a sheet written on a typewriter. A part of it was so badly copied that it was almost illegible. As I have the original book in question I read Ellis' instructions from that instead of his copy of it. Now, Bolton Hall copies his instructions from a little book sent out in 1905 by Finney Sprague, of Chicago. It was Mr. C. E. Ford who raised the great crop of potatoes, and after spending considerable time in trying to understand *how* he did it, I am satisfied that Bolton Hall has made of this thing a blunder. Ellis *copies* this blunder, and it looks to me as if he did not know enough about growing potatoes *himself* to recognize his blunder. He sent me over a hundred questions to answer. Then he sent me his replies to the answers I gave. The supposition or claim is that he answers each customer according to *his* special needs. It does not seem to me that this is true, however, for many of the answers, or nearly all of them, are copied from something written on the typewriter. Like the patent-medicine quacks, instead of answering each applicant's questions *individually* he has a lot of printed sheets sent out, printed on some copying machine.

I am sorry to find so much fault, for friend Ellis' instructions are mostly good and valuable. But every thing he mentions is already found in the nicely printed books on potato culture which I have already mentioned. I explained to him that I spend my winters in Florida, and he tried to give me instructions that are applicable to my Florida home; but you can imagine about what instructions one would give

who had never been in Florida, or at least who had never grown potatoes there. As an illustration: He gives instructions how to handle *bugs* in Florida, when neither a Colorado bug nor a flea-beetle (those two great pests here in the North) has ever been seen in Florida—at least in Southern Florida, where I am located.

Once more, let me say in closing, look out for the man who has a system or secret in regard to agriculture, to be sent for a certain sum of money. If he has a good up-to-date book to sell at a reasonable price, by all means give him encouragement, and increase your knowledge and information at the same time.

BLEACHING CELERY BY MEANS OF STIFF PAPER INSTEAD OF EARTH; RAISING POTATOES

FROM PEELINGS.

I am quite sure that your readers of the North would be benefited by a detailed article regarding the use of paper for bleaching celery—the kind and quality of the paper; proper time to put it on, if it could be described; how it is wrapped and tied; whether it is expensive; whether it can be used to advantage in the North, etc.

Throughout the North, hilling is resorted to in order to bleach celery. This is quite laborious, both to pile the hill and then to level it. In my section we plant the young plants 6 inches apart in the rows, ten in a row, with rows about 8 inches apart. This will cover a space from the first plant in the row to the tenth one of nearly 5 feet; and 1000 plant-hills will make 100 rows 66 feet. It must all be hilled by hand—quite a bit of work when very little results.

When it is considered that the pile of dirt is little or no protection from freezing, and that we must also use a litter covering, I believe that paper might be profitably used, and with the litter would be a better protection than dirt.

Regarding your statement that whole large potatoes are the best seed I quite agree; but when seed is selling in excess of two dollars a bushel the poor man must resort to subterfuge. During the past winter and spring I had the good wife save the peels of those she cooked, cutting a little deeper at the eye. During January and February these peels were planted in the hot frames, and after March in the open ground; and while we may have secured a larger yield had we used large whole potatoes, yet the experiment was quite successful.

Lake Roland, Md., Sept. 29. BENJ. B. JONES.

Friend J., if I am correct, pretty much all the celery produced in Florida is now bleached with a heavy kind of paper that comes in rolls made expressly for that business. I do not know how far it has been used here in the North; but in the South it seems to have taken the place of earthing up entirely. The paper is held in place by means of laths or similar stakes. They are pushed into the ground and held together at the top by means of wire looped around a stake on one side to the stake on the opposite or other side of the row. If it is carefully handled, it may be taken off and laid away and used season after season.

In regard to growing potatoes from

potato peelings, I remember seeing some that were thrown out to the chickens, and which were covered up with dirt where the hens were scratching. Some good strong sprouts started up, and I transplanted them into the garden and had some fine potatoes.

Poultry Department

"NOTHING NEW UNDER THE SUN;" CONVERGENT POULTRY-YARDS, MUSTARD, CHICKENS, ETC.

I thought when friend Stoddard gave us the convergent poultry-yard it was absolutely a new thing, or at least I had never heard of any thing of the sort; therefore I was considerably surprised to find something of the kind already in operation for the dairy business. And now comes the following from away off over the sea from the Isle of Man:

I notice in GLEANINGS, Aug. 15, your remarks about the convergent poultry-runs. According to Lewis Wright, in the poultry-book of 1902, a Mr. Dunbar, of Bedford, Mass., had a plant of your description built and planned by O. H. Payne, C.E., and stated that it had been described and illustrated in the *Reliable Poultry Journal*.

About mustard for poultry, I use a teaspoonful for six birds. I inclose a cutting giving details of an experiment with mustard, and also the reason for its action.

Your special numbers have been first class; but what about goats? I have two nannies—Angelo-Togs, and each goat gives three quarts of very rich milk just after kidding, and keeps in profit from 7 to 8 months. This saves buying milk; and a penny saved is a penny earned.

W. A. TEARE.

Ballashellan, Ballabeg, Isle of Man, Sept. 9.

From the above it seems the idea was in print in 1902, with the suggestion that the same thing has been described and illustrated from our good friends of the old *Reliable Poultry Journal*. Did you ever? But that is not all. It seems also that the recent story about mustard for poultry is only a revival of something published some time ago away off across the waters, and that over in England there is and has been for some time a preparation on the market called "Colman's poultry mustard." Our good friend who writes the above letter submits several pages of what I take to be an advertising sheet for mustard, put out in August of the present year. Full particulars are given in regard to some very careful experiments, and you know our English cousins are always a careful people. The outcome of all this, so at least the advertising circular states, is that mustard not only very largely increases the number of eggs laid, but it also enhances the fertility and the strength and vitality of the chickens after they are hatched. Now can not somebody in the United States advertise and furnish "poultry mustard" at

Where very large potatoes are put on the market, and the potato seed is expensive, your suggestion of taking a very thick slice of paring, and planting the buds or sprouts, would no doubt effect quite a saving in expensive seed.

a considerably less price than the ground mustard of commerce? Our good friend Teare also sends us a leaflet from the "Mark Lane Express Almanac" for 1910, and this leaflet speaks of the advantages of liming the soil when growing clovers, etc.

CAN A MAN KEEP CHICKENS ON $\frac{1}{4}$ CENT PER DAY PER HEAD?

It seems that the statement by Mr. Frederick Martin, p. 772, Dec. 15, 1911, would be more helpful if he would be more explicit as to what he fed those 300 fowls, and prices of food at that time. "Every thing purchased that was fed," and fed them at a rate of 76 cents per head per year! Of course we see it to be less than $\frac{1}{4}$ of a cent a day per fowl. Will some one kindly have Mr. Martin tell us how he did it, or give me some means of finding out how it was done? How many bees and chickens can be profitably kept on one acre of land surrounded by orange-groves and alfalfa, using half of the acre for alfalfa, the other half for yards? I do not care to keep more than 40 stands of bees; but I should like 300, or as many as I could handle, of laying hens on one acre, which is good land, provided with plenty of running water.

Redland, Cal, March 1.

ARTHUR HEAD.

My good friend, you are right in thinking that 76 ets. per head per year is very low; but a good deal depends on the kind of chickens and the price of grain. If you have an acre of ground well stocked with alfalfa, the alfalfa itself will go a great way toward keeping chickens. But generally speaking, I think 300 chickens on an acre is rather heavy stocking. Where alfalfa succeeds, there is probably nothing better than chickens, for it furnishes them both green food and a ration that is almost equal to grain besides. If Frederick Martin sees this he can, perhaps, give us more definite information in regard to the matter.

MUSTARD FOR CHICKENS, ETC.

It is not very often that we find in the Sunday-school lesson suggestions for feeding poultry; but in the "Pilgrim Lesson Leaves," in discussing the lesson for July 21, we find the following:

Dr. William Hanna in *The Designer* has an interesting travel note on this verse [Mark 4:31]. He says:

"Nowhere in the world does the mustard plant attain such size as it does along the shores of the Sea of Galilee, on account of its very rich soil and its abundance of sulphur. One particular clump of mustard plants was as high as our heads as we rode through it on horseback, and it was full of hundreds of twittering and singing goldfinches

which feed upon the seeds. Now, there is nothing irritating in the seed itself, because the activity of powdered mustard is brought out only by the addition of water, and therefore these little birds could feed upon the seeds with impunity. This explains the parable which was uttered on this very shore of the Sea of Galilee."

As you will notice, it is a comment on the 31st verse of the 4th chapter of Mark. Note also the statement that the mustard grows to a mammoth size on account of an "abundance of sulphur." Now, there is so much sulphur in the artesian well water in Florida that it is offensive to most people. Well, I have before remarked in regard to the wonderful growth of various kinds of mustard in Florida. In fact, all the *Brassica* family seem to flourish without any fertilization. No doubt the wild birds feed on the mustard with impunity; and here is a hint explaining the fondness of domestic fowls for mustard in any shape whatever; and I am sure this same mustard is not only conducive to their growth, but it is also conducive to a large yield of eggs. Feed your chickens green mustard, all they will eat; and when you can not get green mustard, give them mustard in their mash, and they will reward you with an abundance of eggs; and not only that, but eggs that are strongly fertile.

A PERAMBULATING POULTRY ESTABLISHMENT.

Our friend Philo has made quite a sensation, not only throughout the poultry world, but throughout the general world, in developing and *demonstrating* the feasibility of growing our own eggs in the back yard. Well, the letter following goes a step further, and suggests that when you want to take a pleasure excursion through the country, or when you wish to migrate from one State to another, you can just load your chickens into the wagon with your household effects, and have fresh eggs right along on your trip, without any profit going to the middleman. Read the following interesting letter and see if I am not right about it:

I brought 20 White Wyandotte hens with me from my old home in Pueblo Co., Colorado. We came by wagon through the Pan Handle of Texas, and were on the way from May 6 to July 2. They were in perfect health all the way, and made a good egg record (we kept strict account), and are still doing all that hens can do. Since we stopped traveling they have wanted to sit, and have hatched 41 chickens, 40 of which are living, and are sturdy and fine-looking. We can raise chickens each month in the year here. Our soil is rich in lime, potash, and magnesia, but it lacks humus and nitrogen. We are thinking of trying sweet clover. People here have never seen it, and do not know what it is. This is a peculiar mountain-plateau or high valley—8000 feet. It seems strange and dreary to us; but we must live here for a while. The climatic conditions and the water from the big government spring are all that was claimed for them. Our minister said last Sunday, "Your country is like

the Holy Land in many respects." Our grain crop here is maize. One little seed will bring several short stalks, each producing a head composed of many grains—often a "hundred fold." Fort Stockton, Texas. MARY M. McALLISTER.

My good friend, I not only rejoice that your biddies kept on laying on that long trip of 57 days, but to know that you are attending *church* in your new home, and that you have found an abiding-place like unto the Promised Land. I should like to know more about that kind of maize that yields, *many times*, a "hundred fold."

THE "POTTER SYSTEM," ETC.

I laughed right out aloud when I read of your opinion of the way Potter does business. I want to say a few words in regard to that system. The system is all right in a good many cases, and no doubt Potter ought to have some credit for having his little dollar book printed; but I don't believe he ought to have the credit for originating the "system" or discovering it. I also bought his book some five or six years ago for \$1.00; and when I received it I read it; and, after finishing it, I sat down and laughed, not because there was anything comical in that booklet, but simply because I was foolish enough to pay \$1.00 for something I had known for years, or long before I had ever seen a poultry paper or a system advertisement, and I have read poultry papers now off and on for some 16 or 17 years. I am 34. When I was seven or eight years old my mother would have us children go into the coop with her and catch the hens for her; she would tell them in the Potter-system fashion, and would tell us which hens would lay and which would not. Then we would pen up the layers and let the others run at large. Especially would she do this mostly in the spring, when the chickens would commence to steal nests under buildings and woods.

I have invested in two such systems, and have heard or known of those same things before, so I have quit that part of the purchasing end of the poultry business, and find I am money ahead by using a little common sense with good wholesome food and less "system," so called.

JULIUS F. RIPCZINSKI.

Minneapolis, Minn., March 12.

CHICKENS—FREEING THEM FROM VERMIN BY GIVING SULPHUR IN THEIR FEED.

Some time ago I expressed some doubt about sulphur having any effect on vermin when fed to chickens. In reply the following comes to us from away off in South Africa:

Mr. A. I. Root once wondered if sulphur in the food of chickens could clear them of vermin. Let him take (eat) daily for a few days a dose of sulphur in any form, and soon he will find his silver money, silver watch, or pencil-case, etc., blackened by the sulphur-gas compound emanating from his sweat.

Potchefstroom, S. Africa, Sept. 15. J. E. DYER.

INDIAN RUNNER AND PEKIN DUCKS.

I have eleven of the Indian Runner ducklings three weeks old. I hope they will lay in winter; but our winter here is so much colder than yours, possibly they will not do so well.

I have two yearling Pekin ducks which have laid to date 222 eggs. The first egg was laid February 23, which I think compares very favorably with the Runners. Last year they averaged 89 eggs each, and I have read in duck literature they are not profitable the second year.

Knowlton, Que., June 27.

S. M. BULLARD.

Temperance

IMBECILES, DEGENERATES, ETC.; SHALL OUR GOVERNMENT CONTINUE TO FOSTER AND ENCOURAGE THIS SORT OF "CROP"?

I have before spoken of the American Medical Society; and I have been assured that it is the best authority in the land in regard to the safeguarding of our people. I have also referred occasionally to Miss Minnie J. Ellet as a woman who has been for some years indefatigable in this matter of rousing our people to the importance of getting legislation for the protection of our boys and girls. Below is something which she furnishes:

STATISTICAL WARNINGS AND ALCOHOLIC DEGENERACY.

Dr. F. A. MacNicholl, vice-president of the American Medical Society, delivered an address before that society at Atlantic City in June, on alcohol and degeneracy. He declared: "Mainly because of the appalling increase in the use of narcotics and alcohol a wave of degeneracy is sweeping the land—a degeneracy so appalling that it staggers the mind and threatens to destroy the republic." * * * He tells how modern scientific methods have reduced the mortality from acute diseases; how the sources and carriers have been discovered and destroyed; but he laments the marked contrast with which the nation deals with alcohol, "that most potent source and carrier of chronic diseases of heart, liver, lungs, and other organs."

He further says:

"A study of the United States census shows that, within a period of fifty-three years, the population of the United States has increased 330 per cent, while the number of insane and feeble-minded has increased 955 per cent."

He says: "Statistics compiled by leading insurance companies of Great Britain show that, in every 1000 deaths, 440 are due to alcohol. This same rate in the United States would mean a mortality from alcohol of 680,000 a year."

"But the great burden of drink is not borne by the drinker, but by the drinker's children. The germ cell that is to be evolved into another being is the most highly organized of all the cells in the body. In its protoplasm lies the material and pattern of the perfected organism. Should such poison as alcohol lessen the nutrition of the cell or impair the quality of the protoplasmic material and deface the pattern, these shortcomings and defects will be manifested in the subsequent stages of development."

He tells of a hospital in New York for the treatment of physical defects, in which every patient was the child of drinking parents. He says further:

"One-third of New York city's schoolchildren are mentally deficient. If this percentage holds good over the entire country, there are seven million children of school age who are mentally deficient, and fewer than 67,000 of these are free from hereditary alcoholic taint. A nation half diseased and half well can not live; but here we have three-fifths of the rising generation mentally and physically diseased."

"Not long ago a call was issued for young physicians to enter the United States army. Eighty per cent of those examined were rejected as physically unfit. When four-fifths of our most representative men are pronounced unfit for war, what shall we say as to their fitness to father the next generation?"

"Boards of health, armed with police power of state, eradicate the carriers of typhoid, and quarantine the victims; but alcohol, a thousand times more destructive to public health, continues to destroy. Alcoholic degeneracy is the most important sanitary question before the country; and yet health authorities do not take action, because alcohol is entrenched in politics. Leaders in politics do not act, because their political destiny lies in

the hands of the agents of the liquor traffic. We are face to face with the greatest crisis in our country's history. The alcohol question must be settled within the next ten years or some more virile race will write the epitaph of this republic."
East Akron, Ohio. MINNIE J. ELLET.

THE LEGALITY OF THE TREATING LAW.

It transpires that my department has a good friend located in the very heart and head of our nation, and here is what he says:

Mr. A. I. Root:—As a reader of GLEANINGS I have noticed with much interest your vigorous wielding of the cudgel on the live moral questions, including that of temperance, and as of possible interest to you I enclose a page which I have torn from a weekly publication of court decisions, containing a discussion of a case that was decided by the Supreme Court of the State of Washington holding a "no-treating" law to be constitutional, and valid.
CHAS. J. WILLIAMSON.

Attorney at Law, Patent Solicitor and Counsel.
Washington, D. C., Aug. 20.

From the clipping he sends, I extract the following:

It is argued that treating is an act of hospitality which has always been exercised by a free people, and is a right of the purchaser of liquor not to be prohibited. The court answers this contention: "In our opinion it is of no weight whatever in support of a practice which becomes recognized as a source of evil and a menace to public morality and good order. Just as the right to engage in the liquor traffic is not an inherent right in any citizen, neither is it an inherent right in any citizen to treat another in a licensed saloon which is under the control of the police power being exercised by a municipality, as in this case. Whatever the right of the citizen may be elsewhere, he has no inherent right even to buy liquor at such a place." The ordinance is upheld.

"RAISING THE REVENUE" BY SELLING GERMS OF "TYPHOID FEVER," ETC.

The writer in the *Rural New-Yorker* says he "has no more use for intoxicating liquor than for typhoid germs." What would he think if some one should ask him to vote for men or parties that propose to legalize the sale of typhoid germs and raise revenue from it? What would you think of such a proposition? Yet such a policy could scarcely do more harm than the legalized and protected sale of alcoholic poison. Now, there is only one party that always and everywhere proposes to put a stop to this "sum of all villainy," so what is the duty of all temperance people? If members of the Prohibition party act in an "uncharitable and unchristian manner," it is unfortunate; but if the above facts are true, does that fact absolve you or any one else from helping the Prohibition party to ultimate victory? Would it not be more practical for the Anti-saloon League to help the party, and thereby "pour coals of fire" on its head?

I notice you speak of pokeweed. We have eaten the young shoots in spring when about six inches high, including the tender stalk, cooked as other greens.

Savannah, Ga., Sept. 21. CHAS. E. A. HALE.

THE EFFECT OF PROHIBITION IN OKLAHOMA.

See the following, which we clip from the *American Issue*:

The New State Brewery in Oklahoma City is owned by the Anheuser-Busch Brewing Company, of St. Louis. Constitutional prohibition closed this brewery, and a few days after statehood 27,000 gallons of beer was run into the sewers from the vats in this brewery.

May God be praised for what Oklahoma has done and is doing.

Editorial

THE OHIO STATE BEEKEEPERS' CONVENTION.

THE Ohio State Beekeepers' Association will hold its next annual convention at Columbus, Jan. 14 and 15, 1913, with an evening session on the second day. Secretary Shaw, also State Entomologist and State Foul-brood Inspector, is arranging a program. He advises that the editor of the *American Bee Journal*, Mr. C. P. Dadant, and Secretary Tyrrell, of the National Beekeepers' Association, will be present to give addresses on subjects to be announced later. GLEANINGS will also be represented.

This meeting of beekeepers will precede another meeting—that of the State Board of Agriculture on the 16th—and a number of prominent speakers on agricultural topics will be present on that date. There will doubtless be some who will be interested in staying over and taking in the meeting of the State Board of Agriculture.

Our readers may rest assured that Secretary Shaw will leave no stone unturned to make this an interesting and profitable meeting. Columbus is a great convention city. It is centrally located, and all beekeepers not too far away will find it greatly to their advantage to attend.

GLEANINGS FOR 1913.

WE desire to call attention to the list of special numbers for next year as given on another page of this issue. We have spent much time and thought in going over the letters that we have received in response to our call for expressions from our readers in our September 1st issue; we have not been able to carry out all of the suggestions—that is, we shall not be able to devote a whole number to *all* of the subjects mentioned, but we have selected those that the majority have asked for. There have been a great many excellent hints, all of which we appreciate fully. We hope that we shall not have to turn any one down, for we are going to solicit articles from experts to be used at other times during the year in accordance with wishes ex-

pressed by a number of different readers. One of our readers suggests that entirely too little is known about judging a queen. This is true, and some time we hope to devote a whole number to the question; but as this will be impossible the coming year, we propose to use a number of articles on the subject in several different issues. We suggest that some of our old and reliable queen-breeders — G. M. Doolittle, J. P. Moore, H. G. Quirin, etc., tell us how *they* judge a queen. Let us hear from a good many, for this is a subject to which too little attention has been paid.

Another subject to which we shall give considerable prominence during the year, although we shall not devote any one number to it, is the question of shipping bees in carload lots with and without combs. This discussion has been only begun during 1912, and the prospects are bright for some startling results in the near future.

As intimated, we shall devote more space than usual to the shipping and production of comb honey. With the large number of extensive producers who have gone into extracted-honey production exclusively, something must be done to encourage the production of more comb honey. Prices of comb honey are bound to go up out of proportion to those of extracted. At the present rate, extracted will be a glut on the market in the near future, while comb honey will not be obtainable at any price. Such a condition ought not to be.

We have several interesting experiences of beginners on hand that we shall use January 1, but we need more. We can also use more articles from women for the March 1st issue. We desire expressions from some of our largest producers for our April 1st issue. For example, it may be a matter of surprise to some to know that one beekeeper has such an extensive system of out-apiaries that he recently ordered a dozen four-frame extractors, all of which are for his own *personal* use. We hope to hear from him for this special number.

As mentioned in our editorial in the October 1st issue, we solicit answers to the following questions: Do you use an auto-truck for your out-apiaries? If so, what is the saving over horses? Do you have one central extracting plant, and haul the combs to it? Do you have a separate plant at each yard? Do you have a portable extracting plant that may be moved from one apiary to another?

We want the very best that the country affords for our special number on swarming, May 1, and we are willing to pay good prices for it. If you have a good plan that you have tried thoroughly, let us hear from you on such subjects as the control of swarming, artificial swarming, and other methods of making increase.

We have some good material on new and up-to-date methods of selling honey, but we want more. Do not be afraid to tell the other fellow. We will make it worth your while.

For the August 1st issue we desire professional men who have found beekeeping a rest from worry and hard work to tell us of their experiences. If you think beekeeping is ahead of any other pursuit for this purpose, tell why you think so.

We especially solicit good clear photographs that tell a story; for, just as a child's picture-book is a never ending delight to his heart, so the illustrations in our modern magazines serve to break up the solid printed page; and what might be dry and uninteresting is rendered attractive and full of interest. There are other pictures that tell a story in themselves. They are the best of all, because they save the readers time in getting the idea.

SHIPPING BEES IN THREE AND FIVE POUND PACKAGES WITHOUT COMBS LONG DISTANCES.

SEVERAL times in these columns we have mentioned that we are conducting experiments in shipping bees in wire-cloth cages long distances without combs. For a number of years back we have made a success of sending combless bees in pound and half-pound packages all over the United States. During the fall we have shipped bees in three and five pound packages to a number of prominent beekeepers. These were made up precisely the same as the smaller ones, except they were on a larger scale. In lieu of combs, they contained a series of slats standing centrally through the cage. These slats we believe are important, as they provide a means of foothold and of support. Years ago, in our earlier attempts, we found that bees without combs would not

travel as well as those with. We finally came to the conclusion that it was a lack of proper support, and probably a lack of water. Our modern cages are, therefore, supplied with artificial supports—slats—and, during extremely warm weather, a bottle of water. The difficulty of supplying water *en route* has been met by the use of a small tin can with a self-sealing top. This is filled with water, and properly secured in the cage. In the bottom of the tin is punched a hole about the size of a pin. This hole, while very minute, gives the bees a chance to take a drink *en route*. Large holes would not be permissible, as they would allow the escape of too much water, incurring the risk of wetting down the candy and daubing the bees. While we have not as yet perfected this scheme for watering, we feel that, with a little more experimenting, we shall solve the problem to our satisfaction.

As before explained, we have sent, in an experimental way, bees all over the United States, in three and five pound packages. To give the reader something of an idea of the success we have so far achieved, we are presenting here letters from beekeepers to whom we have sent bees across the continent. These will speak for themselves:

A THREE-POUND PACKAGE OF COMBLESS BEES TO THE EDITOR OF THE AMERICAN BEE JOURNAL.

Mr. Root:—Your letter of the 11th and the cage of bees were both received on the 13th, the letter preceding the bees by only a few hours. As it was rather late in the day, they were not hived until the next day, when they were put into a queenless hive. They were in first-class condition, not more than a dozen being dead. It is certainly a success. However, we must say that the weather was not hot when they arrived. It had cooled off about two days earlier here, so that they must have met fairly cool weather most of the way.

We noticed a queen-cage in the box, so we thought you perhaps introduced the queen at the time of shipment. Would you kindly tell me about this, and how you succeed in such introductions? Or was the queen caged temporarily just for safety? Hamilton, Ill., Sept. 16. C. P. DADANT.

In relation to the matter of the introducing-cage which you found, we find it a little safer to introduce these queens in an ordinary nursery cage. The bees are shaken in the box from one or more hives, and then the queen is caged in the form you saw; and in about four or five hours the bees will eat out the candy and release the queen. While 90 per cent of the queens will be accepted when we drop them down into the cage in with the bees, we find we lose too many to warrant continuing that way; but when we cage the queen just before sending the bees out they go through in good order every time, so that the caging is really a precaution.

A THREE-POUND PACKAGE OF BEES TO THE SECRETARY OF THE NATIONAL BEEKEEPERS' ASSOCIATION.

The bees arrived Saturday afternoon in good condition. I did not liberate them until Sunday morning, and I could not see that any had died, other than would have been the case had they been in the hive all the time. The water-can looks to me like a valuable addition to the shipping-cage, and I can not see why bees would not go a long way in that case.

The candy which you had at the opposite end was practically all gone. Of course I don't know how much there was when they started, but it was practically all used up when I liberated the bees.

I am pleased to join in with you in any experiment of shipping bees without combs, and of getting them in the South to ship north for the honey-flow. If the bees can be purchased cheap enough in the South I can't see why the plan isn't practical.

I thank you for the bees. I have them right out in my back lot among the black raspberries.

Detroit, Sept. 9. E. B. TYRRELL.

Mr. Tyrrell has since informed us that the bees are doing nicely.

A THREE-POUND PACKAGE OF BEES TO DR. E. F. PHILLIPS, OF THE BUREAU OF ENTOMOLOGY.

Dear Mr. Root:—I have your letter of the 12th inst., and am glad to inform you that the three-pound package of Italian bees which you shipped on the 10th arrived in excellent condition with not a single dead bee in it. It was very hot here the day of its arrival. I was in Philadelphia at the time, but Dr. McCray took care of them, and put them in a hive with drawn combs at the apiary. When the bees were run in the hive Dr. McCray noticed a small queen.

Dr. McCray reports that the water-bottle in the shipment was practically full when it was received here, so that evidently the bees had not drawn on it very much.

E. F. PHILLIPS, Expert in Charge.
Washington, D. C., Sept. 16.

A FIVE-POUND PACKAGE OF COMBLESS BEES SENT IN HOT WEATHER TO DR. C. C. MILLER WITH A LOSS OF ONLY 11 BEES.

This morning the telephone said, "Bunch of bees at express office for you." Your letter and the card announcing shipment came an hour or two later. The bees appeared in good condition. I prepared a hive for them with empty combs except one comb of solid sealed honey, all but about 25 square inches of brood. I had no idea where the bottle was, and couldn't guess why there was tin on top.

Wouldn't it be a good idea to have the bottle painted and sanded, so as to give the bees a foothold?

Number of dead bees, 11.

Weight of bees, 4 lbs. minus weight of water that escaped after I opened the cage.

You say the weather was hot for ½-pound package. Not only that, humidity was great. Hard to say whether bottle helped. It seems, however, the water must be a help.

The more I think about it, the more I think the tin should be roughened. That smooth tin overhead doesn't seem the thing to hang from.

I didn't tear it open to see, but so far as I can see no candy is left in the cage.

Marengo, Ill., Sept. 13. C. C. MILLER.

We expect in the future to cover the tin bottles with rough paper or thin veneer wood to give the bees a foothold, and insulate them from the cold tin. Bees ought not to have "cold feet" any more than their owners.

A THREE-POUND PACKAGE OF BEES FROM MEDINA TO FLORIDA.

The package of bees arrived on the morning of the 17th, and they were released late in the afternoon of the same day. They were in fine condition—very few bees dead. The water-bottle was lowered about one inch; the food was entirely gone; the weather was very warm—mercury up to 95. It seems to me it would be better to ship in larger packages during extremely hot weather. I see no reason why this package is not entirely a success.

A. B. MARCHANT.

Appalachicola, Fla., Sept. 18.

A THREE-POUND PACKAGE OF COMBLESS BEES FROM MEDINA TO WASHINGTON STATE.

The three-pound package of bees with queen arrived to-day, for which accept my most sincere appreciation. It is really more than I expected. The bees arrived here at 11 A. M. Oct. 5. I took them in hand at once, as they were in a very feeble condition. There were none that could fly. Very few had strength enough to climb on to the combs, so I placed the combs on the flat and spread the bees on them, and in the course of half an hour they were as good as any bees. There was only about 4 ounces of dead bees. The water-can was as dry as a bone. The candy was about four-fifths gone, providing that small space on the end was full when you started the bees. It was here where a large number of the dead bees were, it would seem, for when the bees got dry they all crowded toward the candy. The space was just packed with dead bees; in fact, it was a hard mass of bees, so they could not get at the remainder of the candy. I believe that in four to six hours longer there would not have been a live bee in the box. I don't know what kind of weather they passed through; but here in Spokane it is fine. They were 24 hours longer on the road than they should have been, provided you shipped them Sept. 30, 8 P. M. At that rate they were nearly five days coming.

Spokane, Wash. LEONARD FUNK.

It will be noticed in the case of the bees shipped to the State of Washington that in a few hours more they would have starved to death, as insufficient provision had been made to give the bees food and water. The very fact that the bees were as good as ever after they had been fed shows that more food and water will put them through in good shape even for long distances.

To demonstrate further the feasibility of shipping without combs, we are now proposing to send Mr. Morley Pettit, Provincial Apiarist, Guelph, Ontario, a three-pound package of bees in cold weather. Indeed, we may say that we have recently had a small package that we have kept several days, putting them outdoors in a freezing temperature. After they had been out a few hours we brought them back into a warm room. This procedure of warm and cold was continued for three days. At the end of that time, not a bee died, notwithstanding they were without even the protection of an inclosure other than the wire cloth. We will let our readers know the results.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

A. I. ROOT, "Our Homes," p. 707, recalls this gem, whose authorship I do not know:

The sandal-tree perfumes, when riven,
The ax which laid it low;
Let man, who hopes to be forgiven,
Forgive and bless his foe.

"THE VALUE of honey is attested by its introduction into the German army. Each soldier carries his tube of honey in his knapsack, as experience proves that the use of honey increases strength and endurance on the march."—*Deutsche Imker*, 249. If it's good for the strength of soldiers, why isn't it good for the strength of others?

E. D. TOWNSEND says, p. 725, that two combs with oldest brood are examined; and if no foul brood is found in them the colony is considered healthy. That's for American; it wouldn't do at all for European. European would have to be pretty bad if you couldn't find two healthy combs in every diseased colony. At least that is the case "in this locality."

REIDENBACH, in *Pfaelzer Bztg.*, thinks acid unnecessary in sugar syrup for winter food if water free from lime is used. It should not be heated more than 175 Fahrenheit. Through oxidation formic acid will be formed, and the sugar at least partly inverted. [We have never used acid in making syrup, and seldom if ever experienced any trouble with syrup going back to sugar. The ordinary 2-to-1 syrup (two of sugar and one of water) will be thin enough so it will require some ripening on the part of the bees—that is to say, such a syrup will be partially inverted after it is sealed. If so, there will be no trouble about its sugaring. A mixture of 2½ sugar to one of water possibly would have to have a little acid to prevent crystallization.—ED.]

ON BEHALF of hundreds of beekeepers I want to make a plea that, when supply-dealers make a shipment of a number of packages, each package shall have plainly marked upon it its contents. That would often save a lot of trouble in opening a number of packages before coming to the right one. Another thing, if you don't want to make your customers swearing mad, don't send glass for shipping cases too thick to go in the grooves. That's an outrage that no beekeeper should be asked to endure, and I don't think I ever received glass with shipping cases in which an exasperatingly large number of pieces were not too thick. [We suspect a part of this trouble is due to the fact that some of the manufacturers, in order to get out a case

that would compete with the poorly made cases put out at planing-mills, have made their material too light. If the strips that hold the glass are thin, it is not possible to use a wide groove. The ordinary shipping-case glass is made of scrap glass, much of which is thick, and has to be sorted out before it is put into cases. Supply manufacturers will please take notice.—ED.]

"DR. MILLER says in GLEANINGS that the smoke of cotton rags irritates bees and makes them sting."—*Apiculteur*, 316. Must be some mistake about that. I've used piles of cotton rags without finding that objection, and never heard it made by others. [*L'Apiculteur* is quoting the wrong Miller. It was Mr. A. C. Miller, of Providence, R. I., who said that cotton rags irritate bees. See GLEANINGS, page 664, Nov. 1, 1911, and page 702, Feb. 1, 1912. Our experience has been the same as that of Dr. Miller—or rather, we should say, we have used greasy waste made of cotton, and we have never discovered that it made the bees cross. Indeed, it seems to have more of a quieting effect on the bees than any thing else we have ever used. We have used it exclusively in our apiaries for the last five or six years.—ED.]

A CORRESPONDENT of *Deutsche Bzcht.* says he fed daily ½ pound sugar syrup for 14 days, beginning August 15, and it failed to stimulate to laying the young queens of this year's rearing. He is told that he should have fed honey, for sugar alone is good to keep up heat in winter, but will not do for brood-rearing either fall or spring. [It would be our opinion that there was some functional trouble with the queen. Queens that will not lay under such stimulative feeding should be replaced. We have no difficulty in getting a queen to lay in the fall by stimulative feeding. Very often we find some colonies a little weak about the last of August or the first of September, and then we begin feeding to start brood-rearing. By Oct. 15 we have quite a force of young bees, and a hive full of sealed stores. Such a colony is in prime condition for winter.]

We do not believe that the addition of honey would have very much effect. It is quite possible, in the case under consideration, that no natural pollen was available when the bees were fed, and none in the hive. If this were the case, no amount of stimulative feeding would start brood-rearing. The queen might lay eggs, but that would be as far as it would go.—ED.]

G. M. DOOLITTLE, you say, p. 653, bees will winter in almost any cellar with a proper even temperature. I'm coming to think they'll stand almost any change of temperature with proper air. [We are not so sure of the first proposition; but we are more sure that the bees will stand a considerable range of temperature provided they can have plenty of fresh air. Too much light, however, and a temperature above 60 might cause large losses of dead bees in spite of an abundance of fresh air. It is not wise to strain these propositions too far. On the other hand, Mr. Doolittle's statement is reasonably correct; but in nearly all cases it is almost an impossibility to maintain a uniform temperature of 45 degrees Fahrenheit throughout the winter. At 45 the bees will go into a state of hibernation where the respiration is low and the consumption of stores is light.—ED.]

HENRY REDDERT, you are quite right, as Editor Root says, p. 699, "in believing that the color should be a minor consideration compared to the taste" of honey. Pardon me if I say I think it is, and that you are mistaken in thinking "Beekeepers have spoiled their own game by advocating color for quality." Before there was a bee journal in which there could be such advocacy, there was the same preference by the majority for clover that there is now, and the same preference by a minority for buckwheat. I agree with the majority in preferring honey of lighter color, not because of its color, but because of its flavor, and you may advocate till you're black in the face without making me think I like buckwheat as well as clover. It's all a matter of taste, friend Reddert; and when the majority prefer the taste of the darker honey, the darker honey will bring the better price, and not till then. Neither do I believe, Mr. Editor, that it depends very largely upon what the customer is used to. I know those who greatly prefer buckwheat to clover, and yet they have seldom tasted buckwheat.

ARE YOU NOT just a bit daffy on the safety business, Mr. Editor? Regular shipping cases were considered safe with carriers. Then came safety-cases, which the catalog says "do not require carriers." Then when I raise the question, p. 683, whether safeties without carriers are as safe as regulars with carriers, you say, "We would recommend both safety cases and carriers combined." And then a dim fear is raised that you may have something more up your sleeve when you say, "We believe it is very wise to give comb honey all the protection it can reasonably have." [In the last few

months we have revised our opinion. We have personally seen large shipments of comb honey all smashed down for want of a little care in packing. In some cases it is a lack of safety cases, and in others it is a lack of carriers. Why, then, have we revised our opinion? Because we are convinced that comb honey, even in safety cases, can not be thrown down, piled up upside down, or on end without breaking. The carrier is relatively so much heavier that freight and express handlers can not throw it. It can not stand up on end, and it is too heavy to end up; and it can not be placed upside down. Large quantities of comb honey are broken down in common shipping cases when placed in carriers, showing clearly that the carrier *alone* is sometimes not a sufficient safeguard against breakage. We now believe, therefore, that not only carriers but safety cases should be used.—ED.]

I MENTIONED your preaching "more extracted," Mr. Editor, p. 683, and you ask where. On p. 542, 1910, you say, "There is plenty of evidence to show a tendency on the part of comb-honey producers to go into the business of raising extracted," and conclude by saying, "It is not at all surprising that there should be a marked tendency toward the relatively cheaper article that apparently yields a larger return for the investment." [The quotation referred to on page 542 simply states a condition without any recommendation—at least was so intended. In all the subsequent preaching, recommending the production of *comb* honey, the condition referred to in the quotation relative to extracted was recognized. In our footnote on page 683 we made this statement: "Where did we continue to preach more extracted, as we are now advocating more comb-honey production?" Notice that we use the word *continue*. You have not yet furnished us the quotation called for. We may say, in further explanation of our policy for advocating the production of comb honey, that at the present rate of decrease in the production of comb honey the time will soon come (unless we can turn the tide) when there will be but very little comb honey produced. As we tried to point out, the trouble is not because comb honey is not in demand, but because of the poor and slovenly way in which beekeepers have been grading it and shipping it to market—so much so that the dealer has in many cases refused to handle it. But the public wants it; and at the present time there is a very strong demand for comb honey with but very little in sight, with a large supply of extracted.—ED.]

Notes from Canada

J. L. BYER, Mt. Joy, Ont.

Monday, Nov. 11, a beautiful day, typical of the best weather we often get in this latitude during the period commonly called "Indian summer." Bees are flying freely, and some pollen is coming in from scattered dandelion and marshmallow blossoms. A good flight at this time means that bees in Ontario that are wintered inside will go into winter quarters in good shape, as many will carry the bees in just as soon as the weather turns colder again.

* * *

Colonies in Ontario are going into winter this year *very* populous in *young* bees, as brood-rearing was kept up very late in the season, unlike conditions of last autumn. Although so many old bees were in the hives last fall, yet we had splendid wintering; as a rule, we do not feel like making any calculations as to this year with changed conditions, although an orthodox view would be that many young bees make good wintering. With such a large population in the hives at present, the main danger will be starvation; and, as hinted at in a previous issue, I anticipate that many bees will starve in some yards this winter where no feeding has been done.

* * *

"He was an honest man and a good citizen," page 679, Nov. 1. I thought when reading the death notice of that pioneer beekeeper, J. S. Harbison, that the quotation given and taken from friend Merriam's postal was about the best that one could wish for in the way of an epitaph. "An honest man." Do we really understand what is implied in the term? For surely if *honest* in the best sense of the term, all the cardinal as well as the minor virtues will be embraced in that phrase. Truly "a good name is rather to be chosen than great riches."

* * *

Regarding the matter of nomenclature in bee terms, please notice that I found no serious fault with the use of the word "hybrid" as beekeepers misuse the term. Rather was I saying that, when we generally accept some words in their wrong application, why worry so much over another one on the list, even if it is in using such butchered English as "shook swarming"? The editor of the *Beekeepers' Gazette*, in a recent issue, shows that he is much opposed to the use of the word hybrid, as commonly used by beekeepers; but then I notice he has an "M. A.," hence

naturally would be more shocked at seeing poor English in print that would be the case with this scribbler with no very accurate understanding of words often used in scientific discussions. In so far as I am concerned, I still think it a great mistake that the term "black brood" was changed into the cumbersome "European foul brood;" and the latter term, according to many good authorities, is fully as misleading as the former one could possibly be. Even if the dead brood in this disease is not quite "black," everybody, nearly, knew what was meant by the term, and that is more than can be said of the name now used, as almost every journal gives evidence of some one using the general term "foul brood" when one has to guess which variety of the disease is meant.

* * *

"The honey-board should always be left on the hive under the lid, whether for wintering or through the season, as few up-to-date beekeepers use cloths any more." So says D. Everett Lyon in the *Farm Journal* for April. All of you back numbers who still use a quilt, please take notice. As the writer is among this number, and intends to *stay* there, nothing personal is intended, you see. Mr. Lyon also says that April is the month to make increase. Even after taking into consideration the fact that he is so much south of us, I am under the impression that the date he gives would be too early. Can any one in his latitude tell us if his advice on the question is sound?

[This question involves the use of sealed covers versus absorbents for winter. Our own opinions in the matter have been modified somewhat during the last two years. For very cold localities, or for very severe winters, we are inclined to believe that the sealed covers will not give as good results as the porous cover with warm packing material through which the moisture can pass out and escape. When the absorbent packing is used, there must always be ventilation over the packing.]

As to April being the best month for making increase, that depends. All such statements should be qualified by the general conditions that may exist. We would say emphatically that, for most localities, April is *not* the month to make increase. The average beginner, if he attempts to divide during April in Mr. Lyon's locality, would, we fear, come to grief; and as he is in about the same latitude as ours we are sure he would.—ED.]

Beekeeping Among the Rockies

WESLEY FOSTER, Boulder, Colo.

Editor Root made a slight mistake, Oct. 15, p. 647, in saying that fourteen per cent of the bees were diseased five years ago, and less than two per cent in 1911. This did not refer to Colorado, but to Mesa County.

* * *

The Colorado State Beekeepers' Association will hold its annual convention Dec. 12, 13, at the Auditorium Hotel in Denver, 14th and Stout St. There will be three sessions a day, and live ones too. We should have a larger attendance than for several years. One of the features of the meeting will be the automobile session, when dealers will show the merits of their different makes.

* * *

Robert E. Foster, bee inspector for Montrose Co., and myself, called upon a farmer for the purpose of inspecting his apiary. The time of day was about noon, and the farmer inquired whether we had been to dinner. We replied that we had. He then said, "You better wait a little before opening the hives, for the bees are in to their lunch, and if disturbed they may stick their forks into you."

* * *

THE NEED OF NEW IDEAS IN BEE CULTURE.

Let us soon have work in bee culture at our agricultural colleges and high schools. Twenty or thirty young men could readily find places with beekeepers in Colorado each year if they were grounded in the principles of queen-rearing, making increase, and comb-honey production. Apiary management and system, if taught in a course in agriculture at an agricultural school, would equip a good number of young men to bring money-making ideas to the specialist beekeeper, and help him plan his work in a way that would save many a day's labor.

* * *

H. H. Root tells us, p. 585, Sept. 15, that 2000 patents on hives have been taken out in this country, at an average cost of \$100—that is \$200,000—a large sum, and probably more than 99 per cent is loss. Beekeepers should put it down as a rule that new hives are not worth patenting. The difficulty here is that every one of these hive inventors thinks his invention is an exception to the rule. If one has a new hive or bee appliance in his head he should try it out; and if it proves good he can doubtless get a manufacturer to make them

and give him a percentage or can make and sell them himself. Don't waste money on a patent. If the money lost on worthless patented bee goods were available for commencing co-operative effort the beekeeping world would be far more prosperous. But for the good of co-operation it is best that it should develop slowly.

* * *

THE EFFECT OF WEATHER ON COMB HONEY; HUMIDITY AND GRANULATION.

It has been stated a multitude of times that such and such a locality produces a white, well-ripened quality of comb honey; and it has been the prevailing opinion here in the West that such honey does not readily granulate. There are disturbing factors in these so-called rules. A rainy season during the heavy flow tends to limit the flow, and, in addition, to cause the honey to be stored and sealed before being thoroughly ripened to the thickness that is common with arid State honey. Such honey was gathered this year in parts of the West, and it is white or light amber, but thin in consistency, and will show signs of granulation sooner than would be the case if the season had been drier.

* * *

Geo. J. Kindel, the Denver freight-rate fighter, won out at the primaries for the Democratic nomination for Congress. He is one of the best-posted men on freight and express rates in the United States, and Colorado will be ably represented at Washington with him as our mouthpiece. Those of our members in the Colorado Association will remember what a stirring and vigorous address Mr. Kindel made before our last convention. I can assure western beekeepers that all we need to do is to present the facts of freight and express rates on honey before Mr. Kindel, and he is all action at once. Mr. Kindel states it as a fact that he has never gone before the Inter-State Commerce Commission with a grievance without securing a reduction in rates. That is a good recommendation for him. While Mr. Kindel is running on the Democratic ticket, he has shown his independence by running on the Prohibition ticket when he could not get any of the other parties to place him on their tickets. Mr. Kindel will undoubtedly be elected, as he has been actively engaged in work of a public character for years. It seems the Democratic machine was against him, but he won just the same.

Beekeeping in California

P. C. CHADWICK, Redlands, Cal.

The meeting of the California State Beekeepers' Association will be held in Los Angeles, Dec. 12, 13, 14, probably in the Y. M. C. A. auditorium, as that was the convention place last season. It is hoped that there will be a large attendance from all over the State. There is much work planned that is of vital importance to our industry, and no doubt it will be a busy three days' session. Every one who can possibly do so should be in attendance. If any of your neighbors can go, take them with you. Go; get acquainted, and enjoy a brief respite from your daily toil.

* * *

The morning of Aug. 27 found me making hasty preparations for my anticipated motorcycle trip, which was to be the chief feature of my summer's vacation. Possibly I displayed a bit of nervousness, in part due to my enthusiasm as the time for starting drew near, and perhaps because of the fact that I was not very well acquainted with my mode of conveyance. I had traveled only a few miles at a time on my machine, for it had been in my possession but a short time, and was the only one of its make I had ever mounted; so I felt much the same as would a green hand on a strange horse in not knowing just what it might be expected to do. Bidding my family good-by I mounted, turned my face to the west, and rode down the valley. After passing through several miles of orange-groves I came to a point too low for citrus culture, alfalfa and grain taking their place for several miles, when I found myself nearing the city of Colton, which is the junction point of the A., T. & S. F. Southern Pacific and Salt Lake Railways, and a thriving city of four thousand inhabitants. "A short horse is soon curried," for it took only a few minutes to pass through, during which I turned south toward Riverside, passing through almost a continual succession of orange-groves for six or seven miles. At Eighth Street, in Riverside, I turned east, continuing through the orange-groves for a short distance.

When I reached the foot of Box Spring Grade I confronted an experience such as I had not previously had—that of taking a heavy grade with my machine. I had traveled only a short distance when my heart began to fail me, for it was with difficulty that I could get sufficient power to keep on the move, eventually being forced to pedal vigorously, and even then I seemed to be doomed for a walk up that long grade. I tried about every thing I

knew to increase the power. Finally, becoming desperate, I shoved the idler lever up a few notches. Instantly the machine shot up the grade, but did not continue, for before long I shut off the power and dismounted in order to regain my composure and wonder if it was really true that there was a "fool born every minute."

Mounting again I continued up the grade without difficulty. At the top I looked far away to the north of east into the Moreno Valley, while to the south and east lay the Perris Valley, wonderfully rich, but lacking an abundance of water to make it bloom to its full capacity. I turned toward Perris through a vast grain-growing section. After several miles of travel I was able to see that city in the distance—a small country town of a few hundred inhabitants. From Alesandro to Perris the roads were so perfect that I found myself almost in Perris before inquiring for the home of Mr. Warr, for whose place I was headed. I was informed that I had traveled more than a mile too far. I retraced the distance, and was soon greeted by Harry J., who is partner with his father, owners of 1000 colonies of bees in Riverside County. We were almost immediately called to dinner, after which the bee business was discussed pro and con, with the elder Mr. Warr participating. Father Warr had some very interesting experiences to relate about those golden days of old in the early 80's; but as I have no desire to have my friend subject to criticism, such as has been "handed" me, I will not relate his big-yield stories of 1884 and '86. Suffice it to say, these old-timers have seen yields that are almost incredible these days. The elder Mr. Warr says that, when Harry gets discouraged, he relates those big yields "of old" to him to give new courage.

From their home can be seen a great alfalfa-growing valley, which is of little value to the beekeeper because of being cut almost entirely for hay, and not allowed to bloom sufficiently to produce honey.

After a few hours' visit, Harry and I mounted our machines, and rode several miles over the hills to apiary No. 1. Typical of other ranges in this section, I found very little button sage, the main source of honey being white sage and wild buckwheat. Button sage was much more plentiful a few years ago, but has been largely destroyed by brush fires. Here I will mention the fact that button sage is destroyed root and branch by fire, but the white variety is injured for only one or perhaps two seasons.

Conversations with Doolittle

At Borodino, New York.

FINDING BLACK QUEENS DURING A TIME WHEN ROBBERS ARE BAD.

On p. 454, August 1, 1911, I told how to find a black or hybrid queen in the middle of a bright sunshiny day, when the larger part of the bees were out of the hive, by sitting with one's back to the sun, so that the bright sunlight would make it easy to see the queen as the combs were carefully raised from the hive and set in an empty hive close by. I also emphasized the using of caution so that the bees would not be stampeded, which is generally the main trouble in finding a queen, especially a black one. After reading this, Mr. Crane wrote, p. 615, Oct. 15, 1911:

Hello, friend Doolittle! I want to know if you can do that for an hour when no honey is coming in, without music about your ears in the key of seven sharps. Yet we have been finding them this season for many days, sorting out the old or defective ones with great rapidity. We use a queen-sieve, and are not troubled by robbing.

The first thing that took my attention in reading this was that friend Crane would have the readers of GLEANINGS think that he uses only black and hybrid queens. If this is the case I wish to say that he is entirely behind the times, especially in a locality where European foul brood has a foothold. All black and hybrid bees have mostly "gone the way of all the earth" in this locality through this disease, while the Italians seem to be fully capable of conquering it. Bro. C., you had better get on the Italian band wagon with your department in GLEANINGS. I did not write what I did because I kept black or hybrid bees, for I do not. I wrote it for beginners who had started with such bees.

The next thing to take my attention was that the editor of one of the departments in GLEANINGS should put off hunting out his "old or defective" queens until a time of scarcity of nectar had arrived in the fall. That *will* do if one is sick at the time this should be done; but to allow the beginner to believe that a time of scarcity of nectar is the best time to supersede old, poor, failing queens, is something hardly admissible in the columns of a paper like GLEANINGS. Very poor queens should be superseded in the time of fruit bloom, at which time there is very little trouble in finding even a black queen; for at that time of the year, and in the middle of a good day, two-thirds of the bees will be out after nectar. All

not superseded at the time of fruit bloom should be looked after during the closing days of the white-honey harvest, as this is the time nature seems to provide for this work. I have found that success attends almost every effort of the apiarist along this line at this time; hence I have used this time of the year for this work for a quarter of a century.

Now for Bro. Crane's question about working an hour with black bees during a time of scarcity of nectar without robbing going on. This depends largely on who has handled the apiary previously. If carelessly handled so that the bees have been angered, or if a *greater* carelessness has allowed the bees to get a taste of stolen sweets, then robbers and stings are almost sure to result when trying to find queens at such a time. As a matter of precaution, all doors and windows to every building containing honey should be carefully shut and guarded; and no one should allow himself to leave a section or frame of comb standing around for a *single* minute. If an apiarist has exercised the needed care along these lines during the season, there will be no trouble if the work of finding queens has been put off, so that it must be done at times of scarcity, where an *empty hive or a special box is used* to set each frame in as it is taken from the hive. I often work from 10 A. M. to 2 P. M. without robbers or stings at such times. The one thing that should be impressed upon the mind of the beginner in work of all kinds with the bees is, *carefulness* in manipulation. Too many go to work with a colony of bees as if they were to tear a house or barn down. Covers are jerked up and thrown down on the ground, frames are hauled out with a rush, without properly pushing the rest away from them, so that the bees are rolled over and mangled; and when the hive is closed "the bones" creak and break when doing this, without driving the bees away from the joints of the hives. Not long ago I visited an apiary where every joint at the top of the hives and supers was "carpeted" with dead bees which had been previously crushed, and the snapping of "bones" when the covers were put on made me fairly crawl. I protested, but was met with "My time is worth more than a few bees." No, friend Crane, black queens can not be found at any time of the year under these conditions, unless perchance your queen-sieve will do it.

General Correspondence

AMERICAN FOUL BROOD

A Plan for Simplifying the Second Shaking by Giving the Bees Two Drawn Combs in Addition to Full Sheets of Foundation when They are Shaken the First Time

BY E. D. TOWNSEND

Continued from last issue.

In my first article I mentioned treating a colony for a neighbor where some of the combs in most of the hives were built cross-wise of the frame. The diseased colony had four or five combs built straight in the frames so they could be removed. The other side of the hive (that side containing most of the honey left over from the winter) was immovable, except as the combs were cut from the frame. These combs were cut out and taken to the honey-house, and none of it brought back to the hives. A portion containing brood was burned. I suppose all beekeepers who have had foul brood have been through a similar experience and know what a sticky mess we had. It could hardly be called treating of disease; but still, by proper management it was a success. As it was during the honey-flow, and as this beekeeper had not taught his bees to rob, we were not troubled along this line. The four or five straight combs of honey and brood that were left were spaced about two inches from center to center, in the middle of the hive, the cover returned, and left until the next morning. The last morning all the drip from cutting out these combs was cleaned up by the bees and stored in their combs, and the colony was ready for treatment by the McEvoy plan, the first handling being only for the purpose of putting the combs in shape to treat later.

Two weeks after the first shaking, the weak colony containing the two or three stories of diseased brood are ready to be treated, and are handled according to the plan I explained first, using two empty combs, a clean hive, etc.

I mentioned before that a weak colony is not strong enough to take care of more than a small part of the unsealed brood given them. I will now explain this.

We treat our diseased colonies at the opening of the clover flow, as I mentioned before, as clover is about all we can depend on for our surplus honey at this one yard in question, since the basswood has almost entirely disappeared; and as clover never yields more than four weeks, and in some seasons only two or three, it will be seen that, if we were to wait until all the brood

has hatched—that is, three weeks—very likely the season would be over, and there would be no use of treating the colonies, for they would then be of no value. After just two weeks the colony will be a powerful one; and if they can have a honey-flow lasting a week, the bees will fill their hives and be in good shape for winter.

After shaking we carry the old diseased comb to the bee-tight honey-house. There we cut them out of the frame into a metal washtub, because this kind can be washed easily, leaving what clean comb there may be in the frame. If the remaining combs contain honey we extract it, then cut out the rest of the combs and render them into wax, burning the old brood-frames as well as the combs in the tub that contain bad brood. Never extract honey containing diseased brood. Never extract honey from comb containing diseased brood.

Disease will exist in different stages of development in different colonies. Some will have but few diseased cells, while others will have a large amount of their brood dead, and yet be strong in bees. Still others may be found in the last stage of the disease—their combs nearly a solid mass of dead brood with not enough live brood hatching to keep up the number of workers so that the colony has dwindled considerably. If this condition is not taken care of it will soon be a prey to the robbers, and thus the disease will be carried to other colonies.

We have been accustomed to handle diseased colonies in three different ways, according to the stage to which the disease has progressed, as follows:

First, the colony having but a dozen diseased cells is considered quite harmless. The bees are shaken back into their own hives without disinfecting, direct on to foundation. They need no second shaking.

Second, a colony having considerable diseased brood, but not enough to reduce the number of workers appreciably, is treated as I have described above, with the two empty combs, etc. If the amount of diseased brood does not exceed that in one comb the bees are shaken back into their own hive which is not disinfected; but the two combs are shaken the second time, according to the regular plan I have described. If the colony has a large amount of diseased brood the hive should be disinfected, as I will explain later.

Third, a colony that has dwindled down until it is very weak because of disease is of no account, and is not saved. Bees in

the last stage of the disease are the most dangerous of all, and radical treatment is best in the long run. No honey is extracted from the combs in such a colony, all of them being burned except two which are left spaced rather far apart in the center of the hive. Later on, when no bees are flying, we carefully lift out these two combs, bees and all, and burn them. They can both be carried at once, and drop them on a fire. I should be glad to use chloroform in some way, as it seems cruel to burn the bees. This makes a clean job of the whole thing except the disinfecting of the hive.

While it may not be necessary to disinfect hives when treating American foul brood, we do so with all that have contained a great amount of diseased brood, and we also disinfect the hive where the diseased brood is stacked up to hatch. We have an idea that so much of this brood together is dangerous. The trouble and expense are but trifling, and in some cases it may prevent the disease from reappearing. We use a one-to-one-thousand solution of corrosive sublimate or carbolic acid, and simply immerse the hive parts in this solution. Nothing can live through it.*

In producing extracted honey where American foul brood is prevalent there may be no better system to follow than the McEvoy. The hives should be numbered with good plain figures that can be seen clear across the yard. These ought to be made with paint so they will stand the weather from one year to another. Upper stories containing combs that have never been used by the queen should be provided, the theory being that these new combs can be cleaned up dry of honey by the bees, thus removing all spores of American foul brood they may contain. Combs that have been used for brood-rearing contain many cocoons that absorb the honey so that the bees can not get at it, and this honey is just as likely as not to contain spores of the disease. This explains why it is necessary to use combs for the extracting-super that have not been used for brood-rearing.

Having the proper combs, the plan of producing the honey from a diseased yard is much the same as though no disease were present, except that, before beginning to extract, each upper story should be numbered the same as the hive on which it was filled. The reason for this is that it is desirable to return them to the same hive that

they were on before, in order to get them cleaned from what honey is left after the combs are extracted. And the combs themselves must be returned to the same super, or else the system can not be carried out. If these precautions were not taken, and honey were extracted from a super taken from a diseased colony, then put back over a healthy colony, the disease would be carried and thus spread about the apiary. It will be seen that it is necessary to have the combs cleaned up by the same colony that filled them in the first place before they will be safe to use in hives containing healthy colonies. It usually happens that, when these combs are returned to the bees to be cleaned, the bees clean them and store the honey right back in the one they are cleaning, and this is quite undesirable. Mr. A. H. Guernsey, of Ionia, Mich., told us in one of the conventions how to get the combs clean from honey, and I consider it a valuable kink. He waits until cool weather in October, when the brood is nearly if not all hatched out, before putting them on the hives. At this time bees are naturally carrying in winter stores from the outside combs to form their winter nest. Taking advantage of this trait of the bees, he gets his combs cleaned at that time. I consider this a valuable addition to the McEvoy plan of producing extracted honey in a yard containing American foul brood.

As upper stories can not be used year after year on the same hive, their numbers should be made in small figures with a pencil so that another year they may be used over a different hive if necessary. Some producers number the upper stories with cards which may be changed from one super to another as they are required.

CUTTING OUT THE DISEASED PART OF COMBS.

When we first discovered disease in the yard mentioned in my first article, the colonies had been worked for extracted honey without queen-excluders, and many of the combs in the upper stories had been used for brood-rearing during the season. We decided to follow the McEvoy plan for treating the yard. None of the combs that had had brood reared in them could be used again. As it so happened, we were at that time expanding our business to some extent, so some of the old extracting-combs had been taken to a new yard we were then starting. To replace these old combs taken away, new frames filled with new sheets of foundation has been supplied. Many of these had not been used for brood at all, and others had been used more or less according to the position they occupied in the upper story, or to the inclination of the

* It seems to us that scorching the inside of the hive with burning straw or with a gasoline blue-torch is really quicker and more effective. We should have our doubts about such a weak solution destroying the spores of the disease.—Ed.

queen to go above. With a sharp thin knife, when the combs were warm, so they would not be brittle, the portion that had been used by the queen was cut out and rendered into beeswax, as were also the old black combs mentioned before. See illustration, next issue. After being trimmed, the combs in each extracting-super were one-third to one-half cut away. These were probably about as good as full sheets of foundation in these supers, so we saved some expense (and, we think, some time) by this method.

The next season these upper stories containing frames partly filled with comb were given to the bees promiscuously with apparently no bad effects. Of course the bees were not diseased very badly, for we started the treatment in time.

Remus, Mich.

A PUSH-IN-COMB INTRODUCING-CAGE AND SHIPPING-CASE COMBINED

BY A. V. SMALL

The first queen I bought came in a Benton cage, and I tried to introduce her to a full colony according to the directions on the cage. She was rejected; the bees built cells, and reared a queen of their own. This was in June. In August I purchased another, and she too was rejected.

The next year I raised several queens from swarm cells built in one of my good colonies, and had no trouble in introducing them with the push-in-comb cage.

This matter of getting the queen on to the comb while she is being introduced has some important advantages. She more readily and more thoroughly acquires the colony odor; she and her attendants have access to the natural stores, and she prepares to lay and usually deposits a few eggs before she is released. The colony is very exceptional that will kill a queen that is depositing eggs in their own combs.

My push-in-the-comb shipping-cage is an ordinary Benton cage with the wood cut clear though in the two circular compartments occupied by the bees. The back of the cage is provided with a light tin slide. This forms a bottom for the bee compartment during shipment. The front of the cage is covered with a piece of screen wire extending down beyond the sides and end of the block half an inch or more. When this part of the wire is pushed into the comb, the back or bottom of the cage is brought in contact with the comb surface. Then after the tin slide has been carefully withdrawn, the queen finds herself on the

comb surface, but can not escape from the cage until the candy has been eaten away by the bees of the hive in the usual way.

After the tin slide has been withdrawn, a little piece of screen wire is pushed into the comb at the end of the block from which the slide was withdrawn. This prevents the bees from working their way between the cage and comb surface and liberating the queen too soon.

During shipment the part of the screen used to push in the comb is folded down on the back of the cage, and the cage is covered by a light cardboard carton provided with two or three air-holes next to the screen for ventilation.

I am now using a push-in-comb cage with a spool tacked on one side as shown in the illustration. The spool is filled with queen-cage candy, and the bees can liberate the queen by eating out the candy instead of tunneling under. I like this better than any other introducing-cage I have tried.

North Topeka, Kans.

A Suggestion in Regard to the Miller Record System

The new record system, on page 656, Oct. 15, is a good and time-saving method. The author mentions that the apiary has 200 colonies, but provided for only 199. Could he not put ten colonies in his first group by using 0 to 9 inclusive, and make the apiary of 200 colonies complete on 20 cards?

Lititz, Pa.

L. G. SCHULTZ.

[We see no reason why this suggestion should not be practical. The first row would then have ten hives in it, like all of the other rows. The first hive in each row would then be numbered 0, 10, 20, 30, etc.—ED.]

S. D. Smith, of Auroraville, Wis., who, though nearly 80 years old, cares for 105 colonies of bees.

OVER A HUNDRED COLONIES CARED FOR BY A MAN NEARLY 80 YEARS OLD

BY S. D. SMITH

The picture shows my apiary of 105 colonies. Although I am 78 years old I do all the work myself. I have extracted about 2000 pounds of honey, have taken off a good deal of comb honey, and have a whole lot to take off yet.

Late in the season, even in September, the bees began swarming, and they did nothing but swarm every day, rain or shine. Sometimes three or four came out together and formed a big cluster. All my queens are clipped, so they have to go back, each bee to its own hive. I keep all of my colonies very strong.

Auroraville, Wis.

EXPERIENCES OF A FOUL-BROOD INSPECTOR

Some Queer Hives and Frames

BY J. E. CRANE

Continued from page 727, Nov. 15th issue.

Nearly all the hives in the town where I began the work of inspection contained Hoffman frames; and the first hive I attempted to open I went at with a rather heavy jack-knife. If I remember rightly, the frames filled the hive from side to side.

"Hold on there! you will break your

knife," said the kind-hearted proprietor. "I have a hive-tool that will help you out."

He brought me a large flat file that was too much worn to be used any longer as a file. I believe the end was somewhat sharpened. With this tool I was able to squeeze the frames together and to loosen one so I could get it out. Then the rest came easier. It took some of the conceit out of me when I found that the proprietor could handle those frames in half the time I could as I had never before tried to remove Hoffman frames from a hive occupied by bees, having always used the Langstroth frame.

The next place I visited I started to use my knife again from sheer force of habit, when I was called on to halt, and the owner of the yard called out, "Sonny, run and get a chisel."

I kept hearing this or something like it until "Sonny, run and get a chisel," became a byword with me.

I found several old flat files in use. One man had one with the handle gone and the handle end bent up in such a way that it fitted the end of the frame and could be used to pry it loose, provided one knew how. The inspector was willing to learn. But the reader will inquire whether there were no follow-boards that could be removed. Yes, I found some, but they were often so glued in that often there was danger of tearing them apart in trying to get them out, and I found it more desirable to crowd the frames together as best I could,

Fig. 1.—One of the out-apiaries of F. A. Ticknor, Austin, Minn., who has been a beekeeper for 55 years.

and to loosen the straightest comb and lift it out.

I soon thought I was going to get along nicely, when I began to find hives where the combs, not content with one frame, would bend off on the one adjoining; and some, perhaps joined three or more frames together. It began to look as though "bee inspection" was not going to prove a snap by any means; but I found that, where I could not get into a frame hive from the top, I could tip it up, break out the bottom-bar of the frame, and take out a brood-comb, and inspect.

The second day I was out I found box hives made of grocery boxes, and frame hives with the covers nailed on top so that

they could not be removed with any tool I had with me. The hives were set in long rows about four inches apart, and in all sorts of ways. On the third day I went home thoroughly tired out and generally disgusted — probably not more so, however, than some of the beekeepers I had met. One of these was quite a character, and afforded me some amusement. I was told before meeting him that he might not let me look

his bees over; but I

found him willing provided it cost him nothing. He stood at a respectful and safe distance to watch the inspector examine his ten colonies—seven in frame hives with honey-boards nailed on securely, two in grocery boxes, and one in a hollow log. By cutting away branches of bushes I was able to get at all of them, and my work was quickly done. I assured my friend that his bees were free from disease, and his aparian prospects for the future were bright. He then proceeded to give me an account of his past successes in beekeeping.

"Three years ago," said he, "I was sitting there on the piazza, and I looks up, and I say a *swarm!* Give me my gun! I *shoots 'em!* They come down and lights

Fig. 2.—An out-apiary located in the midst of 160 acres of white clover, the edge of which may be seen in the foreground.

Fig. 1.—P. A. Knoll's winter case for six colonies.

in that tree. I hives them! Three years ago! Ten hives all from one swarm! I no sell very much honey. Honey good on panny cakes. Honey good for colds. Many colds last winter. I come down with one too! Very sick! Most die! I takes a little honey; me better soon. I no sell very much honey. Honey good on panny cakes. Honey good for colds. Three years! ten hives, all from one swarm." I congratulated him on his success, and felt sure he was telling me the truth when he said he sold very little honey, as certainly not more than one of his hives was made so as to take any surplus, and that one very poorly adapted to that purpose.

Speaking of frames, I have found all sorts and kinds — a very much larger proportion of Hoffman than of the Langstroth, however. And then there are styles that I am not wise enough to name. I found one set made two inches wide, top, ends, and bottom-bar, and placed in the brood-box tight together. Evidently, when an attempt to put a colony in such a hive was made, there was no way found for the bees to get inside the frames, so a little wood had been whittled off from the bot-

tom-bars so they could get through.

Another time I found that the proprietor of some twenty old box hives was going to do things right, and was making his own hives, but seemed to have no very clear idea of how things should be. I noticed that his frames were two or two and a half inches wide, and seven-eighths of an inch thick, top, ends, and bottom - bar. These frames were to rest on seven - eighths - inch cleats nailed to the ends of the brood-box.

Another farmer had made his own movable-frame hives, for he said he was a carpenter; but I had to call for a hammer and cold chisel to get into them, although they were of the Langstroth type of frame. It has seemed passing strange that those who have had no experience in beekeeping, or at least in making improved hives, should not first go or send to some factory and get some standard hive for a pattern, and then, if they wish, make their own like it.

I have spoken of the difficulty of getting into hives having Hoffman frames; but this is trifling, compared with what I have experienced in some places where the old style of Langstroth hive and frame was in use, for I could almost always tip up hives

Fig. 3.—The front opened during hot weather.

Fig. 2.—The back of the case opened for inspection.

with Hoffman frames and tear off the bottom-bar of the frame and break out a comb. But what can an inspector do with one of those old Langstroth hives when he finds the bottoms nailed fast with ten-penny nails, and the combs built at right angles, and every other one at the top-bar of frames, and he has with him neither cold chisel nor crowbar. There is nothing to do but to look wise and to tell the proprietor that, so far as can be discovered, there is no disease in such hives.

One of the curiosities I discovered on one of my trips was a swarm-catcher which consisted of a one-legged milking-stool with a bail with which to hang it up in nearby bushes, the swarm clustering under the seat and along down the leg. I was assured that it was a great success.

Middlebury, Vt.

To be continued.

160 ACRES OF WHITE CLOVER

BY F. A. TICKNOR

I am sending two views of one of my outyards, located in the midst of 160 acres of white-clover bloom, as may be seen in the foreground of Fig. 2. A yield of less

than 200 lbs. per colony, spring count, at this yard is uncommon. In Fig. 1, notice the rows of sections of glass ends filled with new white-clover comb honey ready for storage, wrapped in newspapers to make them moth-proof till ready for market.

The scenery here is beautiful, and the atmosphere is laden with the fragrance from the clover. The concrete hive-stands are ideal, giving the wingless queens the opportunity to crawl back until their "cases are called." I have had 55 years of bee-keeping.

Austin, Minn.

A WINTER CASE HOLDING SIX COLONIES

BY L. LIST

Because of the heavy losses during the last cold season, the subject of successful wintering has acquired a new interest. There seems to be a trend back to outdoor wintering. When a veteran beekeeper like Mr. Holtermann abandons his well-built cellar and returns to that other mode of keeping his bees through the cold season, it is certainly significant. Because of this renewed interest in outdoor wintering, the

accompanying photographs may prove to be of interest.

Mr. P. A. Knoll, of Frankenmuth, Mich., has designed a hive-stand which, though it contains nothing essentially new, yet seems eminently practical for the purpose. The first illustration shows its appearance in winter, when the space between and above the hives is packed with straw.

Fig. 2 shows the stand open for manipulation. The upper half of the back wall is hinged, also two-thirds of the top. The raised top is held in position by a support, hinged at both ends and also in the center. The roof is covered with asphalt roofing paper.

In the spring the packing is removed and the lower half of the front side turned up, as shown in Fig. 3. In this way the stand furnishes an ideal protection against the scorching rays of the summer sun, making extra shade-boards superfluous. It is, therefore, a winter and summer stand combined.

A recent contributor showed how he gradually moves his hives closer together before packing them in the winter boxes. That is unnecessary with the stand shown here. On the approach of winter, straw is, in a very short time, packed between and on top of the hives, and then they are ready for whatever may come. Any one handy with tools will be able to construct

it, or he may have it built by a carpenter. It certainly will prove to be a good investment. Heavy winter losses may give you a severe setback. Thousands of tons of nectar were not gathered this season because the poorly protected bees had been killed or at least badly weakened by the frost. Surely, the time to prepare for a good honey crop is the year before.

Fig. 4 shows several stands side by side, and also several hives in the open. In some of these the combs melted down in the fierce heat of the sun.

The stands are 11 ft. 2 in. long, and hold 6 to 7 hives of the ten-frame size.

Detroit, Mich., Oct. 1.

A YOUNG ENTHUSIAST IN BEEKEEPING

BY J. F. KIGHT

About 30 years ago I lived in the southern part of this State, and I caught the bee fever from seeing some of A. I. Root's literature. I at once went to work to become a beekeeper, and soon had about 200 colonies. A business proposition called me to the county-seat, so I disposed of my bees; but I have never lost my love for them and their product.

My six-year-old daughter was also inter-

Fig. 4.—The cases in summer furnish adequate protection from the hot sun.

J. F. Kight and his grandson, who is his assistant in the apiary.

ested in my bees, and printed a little letter as follows:

Dear Mr. Root:—My papa has bees that he got from you.

VIOLA KIGHT.

In a few days she received a letter in reply that she has never forgotten. The little grandson in the enclosed picture is a descendant of the writer of the above letter. He is my helper. If I light the smoker and hand it to him he will do the rest.

Southport, Ind., July 23.

SWEET CLOVER, BOTH WHITE AND YELLOW

BY FRANK COVERDALE

I am still testing out both alfalfa and the different varieties of sweet clover side by side. The yellow biennial differs somewhat from *Melilotus alba*—more particularly in that it will not grow a cutting of hay the first year, and ripens too early the second season. Those two points prevent me from growing this species to any great extent on our farms. The white kind makes two long seasons of splendid pasture, and will, during the same period, produce three times as much hay. Alba has this season, under test, made three heavy cuttings of hay, while the yellow gave only one cutting and but little seed. Alba will (and has this year) give one cutting and a heavy crop of seed; and, by the way, we are hulling our seed to-day, Sept. 25; and that which was mown for hay, and cut later for seed, made a splen-

did yield of excellent seed, running out so fast that 125 bushels was run out in three-fourths of the day. Next week we shall make hay from seed of alba that was sown April 5, and pastured to the ground till June 1, then cut back on account of rag-weeds, and it is now ready for over one ton of hay per acre. Yellow will not do this; still, I will make more experiments with this variety. I have not yet tried it out at the last plowing of the corn.

I have a strong hope that this clover will prove to be of vital importance as a plow-under crop in time to put the field to corn. Our tall, slender-growing white kind is far superior as a general farm crop; and it is very important that a right type of it be grown upon the farm. This has been our experience. I had inquiry for upward of 2½ carloads of sweet-clover seed during the past year, and received only two small inquiries for the yellow; so I am compelled to believe that the demand must be limited. Our seed germinates as well as any other clover here; but still I have noticed that seed harvested too green has failed to come up as it should. We have learned to let our seed ripen well before cutting.

I am now writing a series of articles for the *Dakota Farmer*, and hope to put the things of importance before the farming community. I am now making some scientific investigations, and will set forth the proofs. Alba is the greatest storer of nitrogen in the soil of any clover that

grows, as well as the greatest producer of humus of all the clover family. There is certainly a future for this clover.

Delmar, Iowa.

[I confess the above seems rather discouraging in regard to the *yellow* sweet clover; but *this* certainly must be true: Not only are there different varieties of the yellow (annual and biennial) but the yellow of both kinds behaves differently in different localities; and, by the way, I might mention that up to date in our Florida home we have not succeeded in growing any kind of sweet clover, even with heavy applications of lime. Alfalfa grows fairly well with heavy fertilization, but it usually dies out during the summer, in consequence, perhaps, of the excessive (warm) rains.

Now to get back to yellow sweet clover. Years ago, while visiting Prof. A. J. Cook, in Michigan, one of the students called our attention to several stalks in a rank field of white sweet clover, and these stalks were all yellow, and just as rank and luxuriant as the white. Furthermore, I mention, at the end of our sweet-clover book, yellow sweet clover higher than my head, growing profusely along the roadside. Last, but not least, our experiment stations this past season had the rankest growth of sweet clover I ever saw, and with the greatest amount of bloom to the square rod, and this was yellow sweet clover. I am well aware that the annual sometimes, and in some localities, blossoms when only a foot high or even less,

and sometimes does not seem to get much taller. We submit a picture of friend Coverdale's field of sweet clover with cattle grazing on it.—A. I. R.]

FASTENING FOUNDATION WITH MELTED WAX

An Improvement over the Aikin Plan

BY WM. A. SEDDING

I want to tell how I use the R. C. Aikin device for fastening foundation in frames as described in the June 15th issue, 1911, p. 373, with improvements of my own. I nail one inch from the top a strip of board $1\frac{1}{2}$ inches wide and the whole length of the board in place of the handle, as shown at B, and bend the two nails at the bottom, which are pretty stout finishing nails, upward to an angle so as to hold the top-bar of the frame when the board is set on the table or work-bench before me like a music-holder.

Along the lower edge of the board is nailed a piece of tin, bent as shown at A. I made this out of a tin rabbet, and it is for the purpose of making a crimp in the foundation before fastening it with hot wax to the top-bar that has no groove and wedge.

I insert the foundation in the tin groove and flop it over flat on the board. This makes a nice crimp $\frac{1}{8}$ inch wide. Next I lift it up and drop the crimp over the edge of the tin and put my frame on the nails,

Frank Coverdale's field of sweet clover with cattle grazing on it.

pushing the same up close to the foundation, which will fit snugly to the bar, and then run the wheels over the wires. Then I lift the frame off the board with the foundation imbedded, and run hot wax along the back of the crimp. On the other side, along the edge of the crimp, I use a nail which is kept hot on the coal-oil stove where the wax is heated. Not a drop of wax will run under the foundation, and the work is all done in one operation which does not take longer than Mr. Aiken describes.

In order to put foundation in Madary top-bar frames I use it without the crimp, and put the frame with the cut-out side face down, which will let the foundation slide down into the groove before I let the wires take hold of the foundation. Those Californians who use Madary top-bar frames will find this device very convenient because it turns out as nearly perfect work as can be desired. H. E. Thayer, page 254, April 15, says that the foundation drops out of Madary frames. If he tries this plan he will change his mind, and he will see that he can not pull the foundation out,

What happens if no foundation is used. The shallow frames in this super were accidentally overlooked, and put on the hives without even starters. The bees built the comb crosswise and in fantastic curves to suit themselves.

foundation and nailed down. The foundation should be as soft as it can be handled. Monterey, Cal.

SOFT SUGAR FOR FEEDING DIRECT

BY ARTHUR C. MILLER

IN GLEANINGS for November 1, page 705, in reply to a query by Mr. T. J. Landrum, you do grave injustice, not only to Mr. Landrum, but also to those persons who have urged the use of soft sugar as a bee food. You said:

"It [granulated] has supplanted the 'Coffee A' entirely." Also: "Generally speaking you would be able to use granulated sugar in any place where 'Coffee A' is called for."

This clause is especially misleading. "A" sugar, sometimes called "coffee A," is more properly "Empire A," and is one of the

no matter what the climatic influences are, if he does it right.

The cleat should be nailed in the center first, and then each end jammed against the

fifteen commercial grades of sugar. It is a fine soft sugar with a faint cream tinge; is slightly moist, and holds that moist condition for a long time; but not so with "C" sugar, however, for this latter dries out harsh and mealy, and this is often substituted when the "A" is asked for. The "A" sugar, squeezed up in one's hand, holds its shape, while the "C" crumbles almost as soon as the pressure is removed.

Neither granulated nor "C" sugar will take the place of "A" sugar for the several uses in bee-feeding for which the "A" sugar has been specifically recommended.

The soft "A" sugar, put in a division-board feeder, and hung in beside the brood-nest, will serve to keep up brood-rearing as well as the most painstaking feeding with syrup, and without the danger of any of the food finding its way into the honey later. The bees will lick away at the "A" sugar until it is all gone, while granulated or "C" sugar will be untouched. The soft-sugar-feeding system is the most economical ever devised—not only for stimulative purposes but also for keeping up brood-rearing in special colonies between honey-flows and for queen-mating nuclei. One pound of the "A" sugar will keep one of my little nuclei supplied for the whole season, and there is no need of daily attention as with the syrup, and no danger of robbing, as with the latter, and as with candy made of sugar and honey.

Providence, R. I.

[*Later*.—We wrote to Mr. Miller, saying that the description of his Coffee A did not tally altogether with the Coffee A of early days. He replies.—Ed.]

I am mailing to you a sample of "Empire A" sugar obtained direct from refiners' agent. By him I am informed that this is virtually the same as the true "Coffee A" of our daddies' time. It is sold under several names, or, rather, is used to fill calls for "A," "Coffee A," "Coffee," as well as "Empire A." It costs now at wholesale (25 bbls.) \$4.97 per cwt.

If you will notice the semi-transparent lumps in it you will see how the moisture (syrup) gathers in it. In a large body this settles and leaves the top part drier. This is the only sugar which bees work on readily in its natural condition, *i. e.*, without the addition of honey or water.

Colonies have been wintered on it without anything else, and that was in southern New Hampshire, but I want to know more about its use thus before I advocate it for such purpose. But for economical stimula-

tive feeding and for nuclei, etc., it is unexcelled.

ARTHUR C. MILLER.

Providence, R. I., Nov. 15.

[The sample came duly to hand. The "Coffee A" we used to get in the 70's was whiter, and more like granulated sugar. The new "Coffee A" looks, feels, and tastes like a brown sugar that we get to-day, only it is pale yellow, not brown. We believe it would be an excellent sugar for feeding direct. We shall get some, and try it next season.—Ed.]

FLOWER POLLINATION

Experimental Proof that Bright Colors are an Advantage to Flowers; Red Coloration and Heat; Path-finders; Flower Fungi; Cross-fertilization versus Self-fertilization

BY JOHN H. LOVELL

The writer very highly appreciates Mr. Ryan's expression of interest in the article on flower pollination, page 653, Oct. 15. His kindly criticisms manifest an evident desire to learn the actual facts regarding the mutual relations of insects and flowers. Undoubtedly in the past there have been wide differences of opinion regarding the varied phenomena of flower ecology. A few writers have gone to one extreme or the other; but the truth lies here, as Aristotle long ago pointed out to be the case in most discussions, nearer the "mean" or middle course. Personally I should be glad of an expression of opinion by other readers. The questions involved are of more practical importance than many beekeepers seem to suppose. The honeybee is compelled to share the supply of nectar annually produced by flowers with hundreds of other insects. It is certainly not a good business policy in any industry to ignore the competitors for the raw material.

Gray, in his familiar lines, had reference to human (not insect) eyes. It is doubtful if he knew there was such a thing as flower pollination. No matter how frequently a flower was visited by insects, the poet would have considered its charm as wasted if no human being ever beheld them.

Are the bright hues of flowers of advantage in attracting the attention of insects? Let us put the question to Nature. The way to question Nature is by experiment. I repeatedly counted the number of visits made by honeybees to clusters of pear-blossoms during a given interval of time. In one instance eight visits were observed in fifteen minutes. I now removed all the petals and watched the denuded blossoms for the same length of time. There were

either no visits in some cases, or in others only one or two.

Again, during a certain time the number of visits made by honeybees and bumblebees to the flowers of the garden squash were counted. There were a great many visits. The big cup-shaped corollas were then cut off close to the green calyx. The result was the same as with the pear-blossoms—the naked flowers received few or no visits.

The flowers of the common borage were then observed in the same way, and yielded similar results—the denuded flowers were neglected. In one of the experiments with borage there were scattered on the ground many partially withered corollas, and twice a bee was seen to fly down to them. With a lens I examined three of the defoliated blossoms, and in two of them I found eight or nine small drops of nectar, so that a bee alighting on them would have been richly rewarded for its discernment.

These experiments show conclusively that bright-colored petals are an advantage in attracting the visits of bees. It is clear that they were guided by the presence of the petals; and that, when the corollas were absent, they spent no time in seeking for nectar in the defoliated blossoms, but confined their attention to the flowers possessing petals. Note that they flew to the withered corollas lying on the ground, which, of course, were nectarless. We can discover brilliant flowers more easily than we can green or dull-colored ones. It would be strange indeed if this were not the case with the honeybee; and it would seem as though a grave mistake had been made. *A priori* reasoning may be safely used when it is confirmed by experiment; and here the experiments will convince any fair-minded person that the bees saw and were influenced by the bright corollas.

Mr. Ryan showed keen observation in noticing the red coloring on the outside of the apple-blossom. In New England the whole outside of the young blossom of the wood anemone (*Anemone quinquefolia*), which blooms during the last of April, when winds are chill and snow still lingers in the ravines, is often colored purplish red. Red coloring may be observed on many other flower-buds, leaf-buds, and on young leaves in early spring. Because a pigment is useful in some instances in rendering flowers conspicuous, it does not follow that in other cases its *role* may not be entirely different. It is believed that red coloration is often beneficial to plants in raising their temperature by converting light rays into heat.

That red coloration does actually raise the temperature can be shown by the following experiment. Place some red leaves, the superficial area of which has been measured, in a small glass flask of water. In another flask containing an equal quantity of water put a few green leaves with the same extent of surface as the red leaves. Place a thermometer in each flask; close them and set them in the sunlight. After a time the water in the flask containing the red leaves will be found to be 4 degrees C. above the temperature of the water containing the green leaves. The water in the second flask will also be a little warmer than at first, as the green leaves produce some heat. On a cold day in springtime, when the air is near the freezing-point, an increase of only 4 degrees C. might be a great benefit to a plant. In the same way red styles may aid the growth of the pollen-tubes.

No doubt some confusion has been produced in regard to nectar-guides by some observers supposing that all dots, stripes, and markings were intended for this purpose. Of course the splashes, maculations, marblings, and variegations produced under cultivation by the artificial selection of the florist have no bearing on this question, except to show that markings can be produced easily by selection. But there are many flowers which have yellow spots, or marks of some color, directly over the nectaries; so, too, there are flowers with colored lines leading directly to the nectar; or in long tubular flowers the path the insect should travel is indicated in various ways. I see no reason why these pathfinders may not be helpful in guiding bees to the nectar, on the same principle that a way blazed through the forest by scarifying the trees is helpful to the lumberman. That such marks are sometimes correlated with the nectaries is shown by the fact that in *pelargonium*, when the nectaries disappear, the nectar-guides also vanish.

No one to-day claims that *all* the markings on flowers are nectar-indicators. Two hues are an advantage in the same flower, since, by contrasting with each other, each is made more conspicuous than when alone. The value of such color contrasts is well shown by the *Compositae*. Here the field daisy has a yellow disk and white rays; the cone flower a dark-brown disk and yellow rays, while the aster has a yellow or brown disk surrounded by blue rays. Red veins in green sepals are probably the result of oxidation and the production of anthocyan as a by-product. Nectar-guides seem no more remarkable than nectar-covers, or the

protection of the nectar from rains by tufts, fringes, and gratings of hairs, or by projecting scales. It is noteworthy that, in some flowers, the wrong path to the nectar is beset with prickles and sharp points. Nocturnal flowers do not have nectar-guides, since they would be invisible in the dark. It is certainly desirable, however, to test the question experimentally.

Irregular flowers have nectar-guides much more frequently than regular flowers. Mr. Ryan thinks that this order should be reversed, and that such marks are more needful to regular forms. In this opinion he seems to be alone. A season's observation in the field should make it clear why regular flowers do not require path-finders. Rotate flowers like the strawberry, five-finger, and carrot have the nectar secreted at the center, where it is largely unprotected, and exposed to all comers. When an insect alights upon the flower the nectar is directly in front of it. As a result, such flowers, if the nectar is abundant, are visited by a great company of miscellaneous insects, as bees, wasps, ants, flies, and beetles. Even the most stupid species readily find the nectar. Many of them are mere pillagers and are of no benefit. I have collected more than 80 different kinds of insects on the prickly sarsaparilla. Recently Dr. Banks, of the Entomological Bureau at Washington, published a list of 382 different species of insects which he had collected on the flowers of *Ceanothus*. Such flowers do not need nectar-guides. The nectar is too easily obtained as it is; they need protection for the nectar. This is afforded in irregular flowers.

Irregular flowers have the nectar deeply concealed where it can be obtained by only a few (sometimes by but one) species of insects. In the island of Madagascar there is an orchid with a nectary 12 inches long, a specimen of which I have seen in bloom in the botanical garden at Cambridge, Mass. There is only one species of moth in that island which has a proboscis long enough to drain up the last drop of nectar. In bizarre-shaped flowers like the turtle's-head, monkey-flower, and bee orchis, the nectar can be found only by the most intelligent insects. Often they are compelled to enter within the corolla through a narrow mouth, or even through closed lips. The turtle's-head, as the name indicates, crudely resembles in form the head of a turtle. The flowers are white, but the lips are red. It is easy to understand that a bumblebee coming to a cluster of flowers would much more quickly find the entrance than if the lips were white.

As a matter of fact, bumblebees do enter the corolla without any delay; but I have seen wasps and flies examining the outside of the corolla for a long time vainly trying to find the nectar. Comparatively few injurious insects ever find their way into irregular flowers. Irregular flowers then require nectar-guides because the nectar is concealed and difficult to find. The fact that they are present in such flowers is certainly a strong argument in favor of nectar-guides.

Mr. Ryan says that the cryptogams (seaweeds, fungi, mossworts, and fernworts) "owe not one tittle to the insect world." On the contrary, there is a family of fungi (the *Phalloideae*) which are called the flower fungi. They display bright colors, and produce a sweet tough mucilage with a nauseous odor. This is eagerly visited by flesh flies, which thus widely disseminate the spores with which the mucilage is filled. Honeybees also sometimes gather the spores of fungi as a substitute for pollen. As a rule, however, the spores of these lowly plants are very effectively distributed by the wind. The spores of seaweed are carried by the water in which they live.

It is freely admitted that insects will gather nectar from green flowers, and honey-dew from green leaves, after these sources of sweet supplies have once been found; but they will not be found as quickly on green-colored substances as they will on bright-colored ones. Let us again appeal to experiment. I accustomed a small number of bees to visit a piece of dull-gray board on which there was a small quantity of honey. For convenience this board will be called the feeder. While the bees were busily at work I laid on the grass of the lawn, three feet from the feeder, some blue floral leaves of the bee larkspur, placed between two glass object-slides, 3 x 1 inch. On the upper glass slide there were a few drops of honey. On a dandelion leaf, also three feet from the feeder, but five feet from the blue floral leaves, honey was also placed. As soon as the honey on the feeder was exhausted the bees began circling in the air looking for more. In a few minutes one bee had found the blue slide; in ten minutes two bees, and in twenty-five minutes five bees; but none had found the honey on the dandelion leaf. At the end of forty minutes one bee had found the honey on the dandelion leaf. In this experiment the advantage was clearly on the side of the conspicuous object. If two flowers were blooming at some distance apart, the one bright-colored and the other

green, the former would be the more likely to be pollinated.

I later repeated this experiment, and performed many others in which the brighter-colored objects received the greater number of visits. From these experiments we conclude that any surface, whether it is bright or dull colored, on which there is nectar or honey, will be freely visited by bees for stores after these liquids have once been discovered; but they will not be discovered as quickly on a surface which does not contrast in hue with its surroundings as on one which does so contrast. In other words, bright-colored flowers have the advantage over green ones.

After a flower has been found by insects the number of visits it receives depends upon the quantity of nectar it contains and not on its color or odor. Many gaudy garden exotics offer neither pollen nor nectar. Honeybees visit them occasionally, as I have observed; but, finding nothing to repay them, they afterward remember their former experience and seldom pay any attention to them.

Mr. Ryan states correctly that the poppy contains no nectar, and apparently thinks that there is, therefore, no reason why it should be visited by insects. The poppy is a pollen flower. Insects visit it for pollen only. The roses are also pollen flowers. During the past summer I was astonished to observe how many bee visitors there were, and how quickly they removed all of the ample supply of pollen from the Japan roses (*Rosa rugosa*) blooming in my garden. There is no need of the roses secreting nectar. The pollen attracts all the visitors required. But bright colors and odors are as valuable to pollen flowers as to nectar flowers.

I see no reason for changing my statement that irregular flowers only "occasionally" revert to the regular form. This is a matter of common observation. The larkspur, violet, white clover, snapdragon, wistaria; sage, linaria, and several orchids are some of the more common flowers which have been known to revert to a regular or wheel-shaped form; but no reader of GLEANINGS has ever seen these flowers often become regular. Mr. Ryan appeals to Mendel's law; and after referring to Mendel's crosses of the different varieties of the garden pea, he adds: "Here, then, the irregular form *unmistakably* (italics Mr. Ryan's) reverted to ancestral stages and produced regular forms" (quoted from my paper in GLEANINGS, Jan. 15, p. 54). Mr. Ryan is mistaken; for in not a single experiment of Mendel's in crossing the

varieties of the garden pea did the flowers lose their papilionaceous or irregular form and become regular. I was so astonished at Mr. Ryan's assertion, that I wrote to one of the first authorities on genetics in America and Europe, and inquired if he knew of any facts on which such a statement could be based. He replied: "I have read carefully Mendel's original paper giving the account of his work on varieties of the garden pea, and it contains no mention whatever of the flowers having lost their papilionaceous character." And he adds that he never before heard such a thing intimated.

Cross-fertilization versus self-fertilization is a most interesting question. I can not agree that Darwin's dictum, that Nature abhors *perpetual* self-fertilization, has been "upset." It will be noticed that I emphasize *perpetual*. Let us inquire first whether cross-fertilization is beneficial or not. Darwin showed conclusively that it is. The offspring of crossing were larger in size, grew more vigorously, bloomed a little earlier, and yielded more seed. Since then we find Dr. Fletcher saying in the A B C of Bee Culture that endless observations have confirmed the accuracy of Darwin's law. The evil effects of constant interbreeding are instinctively recognized, even by barbarous races.

The latest authoritative word on this topic is given by the President of the Carnegie Institute of Washington in his annual report. He says: "Another investigation continued during the year, which involves prime utilitarian application, is that of Dr. Shull on the effects of self-fertilization in maize, or Indian corn. His earlier conclusions, published in 1908, have been confirmed by his later studies. A striking result from the latter is that, other conditions being the same, *the yield of cross-fertilized plants proved fifty per cent greater than that of self-fertilized plants*" (italics ours). Farmers! fruit-growers! Cross-fertilization in plants is not only of benefit to the plants, but it is of financial value to you. A knowledge of this great principle will put money in your pockets.

Look over the plant world and see how wide is the provision for cross-fertilization. All the cone trees are cross-fertilized. In all the species the eggs and sperms are produced in different cones; and where both kinds of cones occur on the same tree, the fruiting cones are in a position where they are not likely to receive the pollen from the staminate ones. How well the cone trees have succeeded! How vast are our forests of pine, of fir, of spruce, and larch!

Most of the grasses and sedges, which in myriads so beautifully clothe the earth, are cross-pollinated. Many of our deciduous trees, like the birch, the poplar, and the willow, depend wholly upon inter-crossing. A multitude of herbaceous plants secure cross-fertilization by the most ingenious contrivances, and there are very few which do not secure an occasional cross.

But if cross-fertilization is so valuable, it may be asked, "Why do so many plants retain the power of self-fertilization?" The reason, it seems to me, is obvious. If a species becomes rare, it is likely to disappear unless it can fertilize itself. Species represented by only a few individual plants, widely scattered, may linger along in favorable locations indefinitely, if they can fertilize themselves and thus produce seed. It is better for a species to be self-fertilized than to perish. There are hundreds of rare species which do thus prolong their existence. It is clear that, if a plant which has lost the power of self-fertilization, becomes isolated, it will be unable to produce seed, and, consequently, will leave no offspring. It is desirable, therefore, for plants to retain the power of self-fertilization against an emergency.

Plants that are regularly self-fertilized have usually small flowers, and are adapted to special conditions. They are stationary or retrogressive forms which are no longer advancing in development. For species which are evolving rapidly, inter-crossing is a necessity. Nature may not abhor self-fertilization, but she does abhor *perpetual* self-fertilization.

There are some exceptional cases where plants rely on vegetative multiplication; and there are flowers, as some species of *Taraxicum* and *Hieracium*, which produce seed without pollination or fertilization; but it would be folly to argue that, therefore, sexual reproduction is of no value. It would be equally a mistake to condemn cross-fertilization because there are some species which are self-fertilized. In deciding as to the application of a great natural law we must take a broad view. I was once present in the United States Supreme Court when one of the justices, in speaking of the application of certain law relating to shipping, said in effect: "We must look, not at one point, but all along the shore, including the Atlantic, the Gulf, and Pacific seaboard, and the shores of the Great Lakes." So should we study a great natural law.

From the list of prismatic colors, indigo was intentionally omitted. The term is omitted from many modern text-books on

color. Prang in his "Standard of Color" does not even mention it. Rood in his "Text-book of Color," says, "The term indigo, originally introduced by Newton, has been entirely rejected in this work." There are objections to the term, and Prang covers the ground by using combinations of the terms blue and violet.

It has been necessary to reply to Mr. Ryan very briefly; but the above statements can be substantiated by a great amount of additional data. We hope other beekeepers will express an opinion. The question really resolves itself into this: Are the eyes of bees good organs of vision? It seems impossible that any man can be a beekeeper for half a lifetime, or for even half a dozen years, without forming an opinion on this matter and being able to give a reason for his belief. There are some phases of bee-keeping on which it is difficult to say anything new; but, so far as we can recall, very few have given their views on the vision of bees. The editor of GLEANINGS believes that they have well-developed sense of sight. So does Buttlet-Reepen, who suggests that, if you doubt it, you stand about ten steps from the entrance to the hive on a morning during buckwheat harvest, when you will have painful proof of their ability to see. Mr. Dadant thinks that bees "can see very far." Notthafft and Plateau, on the contrary, believe that bees are exceedingly short-sighted. What do you think? There must be scores of apiarists who can give some facts bearing on this question. The department editors of GLEANINGS, with their vast experience, must have very definite ideas on bee vision. The question is surely of great importance to all, and especially to queen-breeders. Will you not let us hear from you? We are after the facts—the truth. *Veritas vos liberabit.*

Waldoboro, Maine.

FENCES FOR WINTER PROTECTION

BY R. F. HOLTERMANN

It was with a good deal of interest that I made a study of the special number on wintering, Sept. 1. Such numbers concentrate ideas and writings upon a specified subject, and are convenient for reference.

The wintering of bees is a subject which has received a good deal of attention, and upon which, through pen and tongue, and (may I add?) practical demonstrations, many ideas have been advanced. In this way decided progress has been made; and if we were always able to do what should be done, beekeeping would be on a different

footing. I say *beekeeping*, for I do not confine its effects to the wintering problem alone. Bees, if put in proper shape for winter, build up better in the spring and give a better honey crop. This side of the question has not received the attention it merits.

There is a long-distance view—a vision, if you will—which I have had for many years, which applies to the beekeeping industry in general, and the correctness of it does not reflect any very great credit upon beekeepers; but this view will remain true as long as bees are largely in the hands of those having other business interests.

For many years I have been able to foresee heavy winter losses under certain conditions. One condition under which these losses occur is failure of the late honey-flow in sections where a flow is usual, or where there is any quantity of honey-dew in the brood-chamber, or where the entire apicultural season has been unfavorable. Then there is the constant selection of the most unfit, which often results from our modern methods, when the colony is headed by a queen which keeps the brood-chamber well filled with brood to the exclusion of stores, in such a condition that starvation is likely to occur before spring. Such a forecast should not be possible in beekeeping; but it is true in Canada and the northerly if not the middle States. Human nature remains much the same. A "sufficient unto the day is the evil thereof" policy has ruined many.

"OPEN" FENCES NOT DESIRABLE.

In the discussion about fences, I was especially interested. I have five such fences, each covering ground space from 40 to 50 ft. square. These fences answer a purpose entirely different from a railroad fence. My fences are 8 ft. high, and have for their purpose the keeping of cold winds from the bees during autumn, winter, and spring, and, incidentally (and a very desirable feature), keeping the snow from drifting about the bees. The only object a railroad fence has is to prevent large snowdrifts on a railway track. With a fence built so as to leave openings between the upright boards, surely the greatest amount of *shelter* is not obtained. By an open fence the railway company secures a distribution of the snow; a portion of the snow rests on one side of the fence, and the rest will drift through and over the fence, and thus the snow is distributed over a larger area. In parts of the country where snowdrifts are very prevalent I have seen two such fences on each side of the track in order that the second fence might catch what the first did not. The wind and tem-

perature are of no interest in this matter; but the snowdrift is all-important. I am so particular to shelter the bees from this wind that I consider it quite injurious to the bees to have even an opening under the fence. In a couple of instances where these existed, owing to faulty construction, I have taken care to have them stopped up. On a bitterly cold, windy day, would a beekeeper take shelter in a place protected by a tight board fence, or in one with an opening between the boards, such as is advocated by some writers? I know where I would look for shelter, and I feel so sure that every one else would know that I shall not undertake to answer the question.

With three winters' experience with the tight-board fence in three apiaries, the snow drifted last winter for the first time inside the fences; and the reason for this was because we had two very heavy snowstorms with high winds; but even in this case the drifts which were next to the fences could have been thrown out through the open spaces which the loose boards in the fence afford. It must be remembered that in most storms the wind and snow will blow right across a space enclosed in a 40 or 50 ft. area enclosed by a fence 8 ft. high. The space inside of the fence is not a vacuum, and the tendency to a downward pressure is largely overcome by the air in the bee-yard.

In conclusion let me say I am quite satisfied with tight board fence. I have put up two more such fences this autumn. It is well to get the bee-yard well shaded with trees in summer, as this shade reduces the tendency to swarm, and in the winter the branches of the trees lessen the effect of the wind.

Brantford, Ontario, Canada.

SOME EXPERIENCES IN SHIPPING BEES

The Importance of Giving Bees Water on the Way

BY G. C. MATTHEWS

In the spring of 1911 I went to Colorado to ship several cars of bees to Idaho Falls for a company in Ogden, Utah. Some of the bees were already bought, among which were my own sadly depleted apiaries which another man had been running. The season of 1910 was a hopeless failure, and what bees had not starved were in a sad condition in March, 1911.

At such an early date, foul brood, though present, shows very little, and one must be exceedingly careful to find every part of it. In addition, the ordinary hives need lots of

fixing before they can be shipped; and I was fortunately delayed in shipping until April. I say "fortunately," because the bees were thus given a chance to rear some brood, and become nearly normal. Had they been left in Colorado three weeks longer it would have been more fortunate, for bees should never be shipped when there are few young bees in the hives.

Two cars of the bees—one from Loveland, shipped April 1, one from Sterling, shipped two weeks later—were sent with a comb-honey super on top of each, screened. The two from Longmont had narrow screen frames. All of them had water dashed into the outside combs, which were invariably empty. All were loaded in tiers packed tight in the car, and with two-by-twos between. In short, they were loaded alike, I think, though I did not load, nor have any thing to do with the Longmont cars. But those with the deep screens reached Idaho with much less loss, and all of the living colonies were in far better shape. Was the extra clustering-space on top the cause? It appears so, yet weather may have cut some figure.

In June I loaded another car in Ogden. These were full colonies that had been swarming; but a dearth of honey had stopped it; and they were fed sugar syrup before screening. They too were covered with comb-honey supers — the strongest with two, and in addition the entrances were screened. They were also watered in the same way, and loaded in the day time as the others had been. These bees were kept closed in for three days and nights in all, *during the swarming season*, and were hauled upon hay-racks and beet-racks, and yet only one unusually strong colony smothered, and few bees in any hive were lost. I forgot to mention that the bees were watered at unloading also. Did the large space over the frames, plus the water, insure the success of this shipment? I think so.

During the spring of 1912 I helped to ship five cars of nuclei from California to Utah and Idaho. All of these were weak compared with full colonies; but they were shut in single-story ten-frame hives on six frames, with the screen down on top of the frames, and they were not watered at all. The bees could cluster at the side, but not over the frames. I saw only one car unloaded, and fully half the bees were lost in each hive, while the owner says he usually loses a great many old bees.

Now, this particular car was held up during the heat of the day twice during the trip, to which cause the owner attributed

the loss. The weather also in Nevada was hot when we passed through. But the car shipped from Ogden to Idaho Falls in June, 1911, stood on the tracks through all the heat of the day in Idaho Falls on the second day, though the weather was not so hot. But the bees were three times as strong, and hence hotter.

The difference, as it appears to me, lay not in the weather nor the motion, nor in the extra time of being shut in (the California bees were closed in for five days), but in watering and the clustering-space. If bees can get above the brood they will not smother it; and will not eat it if they have water.

Now just a word about how to water. If one has extra dry combs, water put in these is best; but some use cans of excelsior, tacked in the sides of the hive, quite successfully. I presume that it is best of all to water *en route* with a spray; but it is not necessary for nuclei if there is water in the hive.

If bees are watered at unloading they are not nearly so liable to swarm out when opened, and be lost. A dash of water in each hive suffices. When they are shut in I should say always give water at every opportunity.

Carneyville, Wyo., Nov. 5.

[Our own experience has shown the great importance of giving water on the route. We are convinced that, when it is supplied to them often enough, they will not destroy their brood, and the chances of the bees getting through in good order are immensely improved.]

If ordinary strong colonies are shipped, it is also important to have a clustering-space over the top of the combs. With ordinary weak colonies, such space, according to our experience, is not necessary, but such bees must be supplied with plenty of water just the same.—ED.]

Bee-stings an Eye-opener

The following item was clipped from the *San Francisco Call* of yesterday, Oct. 5. Like lots of others I've had my eyes opened by being stung, but not by bees. Bee-stings usually act on me for a day or two the other way.

Oakland, Cal., Oct. 6.

GEO. MALCOMB.

A PLACERVILLE APIARIST IS SAVED A VISIT TO A SPECIALIST.

CHICO, Oct. 4.—While changing a swarm of bees from one hive to another, George Bailey, who lives near Placerville, and makes a living selling honey, but who has been almost blind for some time because of some ailment of his eyes, was stung on the face and eyelids by several of the bees. Bailey intended to go to Sacramento today to consult a specialist with a view of having his sight restored; but the bees did the work that he intended the specialist should try to do. The effect of the stings has been to restore his sight.

Heads of Grain from Different Fields

Do Bees Lose Their Stings After Using Them on Other Bees?

Dr. Miller's Straw, page 540, Sept. 1, was a surprise to me. On many occasions I have noticed that it is a rule that has few exceptions that bees do not lose their stings when using them on workers, queen, or drones.

The A B C book in speaking of bees living after having lost the sting, says, "The author has seen a colony so infuriated that the bees stung every thing in sight—fence-posts, etc." They surely did not lose the stings in a board. Cotton gloves coated give full protection. Now for the exception.

I released a queen too soon last week, and she was soon stung in the thorax. The bee that stung her lost its sting. I recovered the queen at once and removed the sting, and caged her again with some of her bees. The front leg on the side where she was stung is paralyzed; otherwise she seems all right.

I once saw a very strong colony on twenty combs (three of which were drone) sting hundreds, probably thousands, of their drones to death—no doubt of it. It was 5 P. M. on a hot day some days after the flow had stopped, when these bees attacked the drones. The drones would fly away only to return. After a while I noticed that many a drone had a worker clinging to it when leaving, and those would soon fall to the ground, where the drone often escaped. Often both the worker and the drone flew away. Many times, however, the drone was stung. The worker would then release the drone, turning about and pulling until the sting came out. The worker then returned to the hive; but the drone so stung never flew again. I did not notice a sting being lost. I think a bee that "curls up," as Mr. Holmes says, p. 660, Oct. 15, has been stung in the abdomen. At least the abdomen is very frequently stung. This is my personal observation—not guess-work nor hearsay.

Tola, Kansas, October 22.

P. E. WAUGH.

[Our correspondent, as well as the one who follows, has given some interesting facts to show that bees may use their stings in a wholesale way to kill both drones and workers without losing either their lives or their stings. We certainly have seen cases where the sting of a worker was left in the thorax of a queen. We can not recall that we have ever found a worker or a drone with a sting lodged in its side. We would conclude that bees do not lose their stings when they use them *against each other*. It is probably not necessary that they should; but nature has evidently designed that, when they attack men or animals, their weapon shall lodge in the wound in order that its effect may be much more severe. The mere prick of a sting probably would not have any serious effect on any man or animal; but when the sting is left in the wound to force out all the poison in the poison bag into its victim the effect is tenfold greater.

In this connection it is proper to observe that some other insects do not have barbs to their stings. For instance, the ordinary yellow-jacket can sting several times—or at least it has been reported that it will, while a honeybee stings only once. If any one else has any further facts to corroborate, we should be glad to hear from him.—ED.]

No Stings Found in Bees Stung to Death

Under Dr. Miller's Stray Straws, p. 540, Sept. 1, "Do bees sting drones to death?" the editor says, "We do not believe that nature has designed that worker bees shall sacrifice themselves, etc." I take it for granted that a worker would make the same sacrifice in stinging a worker that it would in sting-

ing a drone. But does it kill a worker when it stings either a drone or a worker?

A few days after I read the Straw I noticed a small swarm out (probably with a virgin that ran off and left them). Anyhow, the swarm came back, and went in with a weak colony that had a three-months-old queen. Knowing that this particular swarm would not be likely to supersede, I looked for a fight. Well, there was a fight sure enough, and I did not try to stop it. I wanted to see how many stings I could find in the dead bees. The next morning I looked the pile over (about a quart), and there was nothing to indicate that they had been stung to death. So far as I could judge, the swarm they went in with had not lost any bees. I'm from Missouri, and want to be shown.

Redlands, Cal., Oct. 22.

M. J. MEEKEE.

Was the Clipped Queen Killed Because She was Unable to Accompany the Swarm?

Does clipping the queen ever lead to trouble when her bees swarm? The following incident would seem to indicate that it may under some conditions. During the past season I was forced to be away from home several days each week; unfortunately, the rest of the family were also absent. I made the best arrangement I could to keep the bees from swarming, giving the queens plenty of room, and, in fact, according to Mr. Dundas Todd, our foul-brood inspector, rather overdoing it. Queens were all clipped, and I thought every thing was all right. My hives were arranged in pairs, with about six-foot intervals between the pairs—just a nice space for a newly hatched litter of chickens; and so, not knowing what else to do (the garden is small, and I had about thirty hives scattered about), I placed the chickens, with the old hen, in a coop immediately in front of two hives of gentle black bees, and left for the day with a peaceful mind.

About the middle of the day a lady visitor found the chickens all dead, and the old hen in bad shape. Also quite a number of dead bees around, and on trying to rescue the hen the lady herself attracted some very pointed attention, and was finally forced to vacate in favor of the bees, which, I understand, were flying in greater numbers than usual, and were very cross. I found every thing quite normal in the evening, and could not account for the accident.

I afterward found a young unclipped queen in one of these hives, and came to the conclusion that the bees must have swarmed out, and, finding that the queen did not accompany them, returned and killed her, and incidentally the hen and chickens, after which they raised another queen.

FRED E. WHITE.

North Vancouver, B. C., June 10.

[Your solution is probably the correct one; but it is possible that the chickens themselves killed the queen, which they might have done if they had acquired a liking for bees, and if a swarm had issued leaving the clipped queen crawling around in the grass.—ED.]

Poison Not Found in the Honey when Fruit-blossoms are Sprayed

On p. 559, June 15, I see the question, "Is spraying of fruit-trees while in bloom injurious to either bees or brood?" While at first thought we might be led to believe that the bees in question were killed by the spraying, I am of the opinion that this can not be; neither do I think that the brood is in any sense injured by the very small amount of arsenic that is usually found in the various sprays used. I have used the Bordeaux mixture and the arsenate of lead very lib-

erally on my trees at blooming time, and have noticed no bad results to either bees or brood. I also analyzed the honey gathered from the trees for arsenic, and found no trace of it by the delicate test made use of by our profession. I am of the opinion the bees referred to died from other causes.

Anderson, Ind., Aug. 1. BENJ. H. COOK, M.D.

Tin Hive Numbers Held by Nail to Hive Body

I noticed in GLEANINGS a desire for ideas on hive numbers. I submit a sample of hive number showing what we use and like. A triangular hole enables the plate to be hung by a shingle nail driven into the hive body so as to project $\frac{1}{4}$ inch. This size, $2\frac{3}{4} \times 4$, is cut from a fair quality of tin

with the minimum waste. The size is also very convenient for the pocket. The sharp angle at the top of the notch prevents the number from blowing off the nail. I don't think much of your cardboard idea.

Palo Alto, Cal.

H. STILLSON.

How to Avoid Foam on Top of Bottled Honey

Kindly advise me how to avoid the foaming on top of extracted honey in jars. In some of the jars it forms, and in others it does not. The honey is from white clover, was strained through cheese-cloth. It was two-thirds capped before it was extracted.

Brooklyn, N. Y.

A. KIRSCH.

[Unripe honey always gives more trouble in this way than that which is thoroughly ripened; but if yours was two-thirds capped before it was extracted we hardly think that this was your trouble.]

It is well to strain the honey through as thick a cloth as it will run through when hot, as this removes a good deal of the air. Then allow it to stand so that the air-bubbles may rise to the top as much as possible. Draw it off at the bottom of the tank, and be careful to avoid stirring or shaking the honey in the bottles, so as not to get the air mixed in with the honey.—ED.]

Chickens that Did Not Eat Bees

To prove an alibi for those chickens, p. 637, Oct. 1, I will give an instance of my chickens, which have had a good opportunity to eat bees but which do not show evidence of such a depraved appetite.

I live in a semi-arid location, away from any irrigated land except my lawn, about 30 feet square, sown to white clover. I keep about 20 chickens, and have 9 stands of bees. The lawn is the only source of green food for the chickens, and there are very few grasshoppers and such insects for the chickens to catch, so one would suppose that, when the bees and chickens were busy at the clover the chickens would eat bees as well as clover.

My bees were blacks, and I requeened them with Italians, which caused me to watch them while

working on the clover to see how rapidly the change from blacks to Italians was coming, and also what the conduct of the chickens toward them was, and I never found them guilty. Later in the season, when watermelons were ripe, I cut the small ones in two and set them where the hens could eat them. The bees found them first, and got busy, and even fought among themselves for room on those melons, which were covered over with bees when "Brigham Young" and his family would arrive on the scene to look after the seeds and pick the melons up a bit to make some juicy spots for the bees to work on. There was a fine opportunity for bee-eating, as the bees were too busy to make room for the hens; and you could imagine Brigham instructing his wives to be careful not to touch dad's bees.

Bishop, Cal.

G. M. HUNTINGTON.

[It is quite evident that chickens, unless they acquire the habit, do not care to eat bees. They probably learn to eat them by picking up dead bees first, and then later becoming so bold as to tackle the live ones.—ED.]

Wintering in an Upstairs Room Not Advisable

I wish to ask you how it would do to winter four stands of bees in an empty house in one room or one in each of four rooms, with the windows closed tight or partly open to allow the bees to fly out and in during nice days in fall and spring.

Bremen, Ohio.

J. C. NAGINEY.

[As a general proposition, it is not advisable to try to winter bees in a building above ground unless the entrances are so arranged that the bees can fly when the weather is suitable. If you remove the window of the room in which you locate these four colonies we do not know that there will be any objection to your wintering them in the manner you suggest. But it will be best to place the hives as close as possible to the window so that the bees, when flying in, will be more apt to go into their own hive. You will probably find, however, that there will be some "drifting"—that is, one or two of the colonies may attract the larger number of flying bees on warm days, so that the others will be weakened.]

If the temperature of the cellar under the house could be kept nearly uniform—between 40 and 50 degrees—we think you would stand a better show of bringing the colonies through in good shape if you place them there rather than in the upper room; then they would not need any opening to the outside for flight; for where the temperature does not vary, the bees may be confined until spring.—ED.]

Four Tons of Honey Sold at 12 Cts. a Pound

My apiary is the most northern of any in Canada—at least, I think, in the province of Quebec. I have 140 colonies, and we have had an unusually good year for clear honey. I expect four tons. I have sold at 12 cents per pound for the last three years. I have no trouble in getting that price. What I have left after my home trade I sell to Ottawa customers.

Yarm, Quebec.

ROBT MCJANET.

Bees Swarm in October

I noticed the statement by S. H. Fuller, Helena, Ark., Oct. 15, p. 668, about the bees swarming the 8th of August. I can go him some better, for my bees have swarmed twice since then—October 8 and again on the 9th. My bees are still storing honey in the supers. I had to put on six supers with partly filled sections last week. This is the latest I have ever known them to store any honey; but every thing is late on account of the overflow last spring.

Marked Tree, Ark., Oct. 21, R. C. GRAHAM.

A Divided Brood-chamber for Cell-building

I desire to know about the divided brood-chamber for the rearing of queens as given in the "Modern Queen-rearing." The answer, I presume, is obvious enough, and yet perhaps my reasoning would be at fault. In the divided-brood-chamber method, are the bees allowed to come directly from the field into the center compartment—that compartment in which the queen-cells are being built, and from which the queen is excluded by the use of perforated zinc? I should also like to know why it wouldn't be just as well to have these three frames at the side of the hive instead of in the center, thereby eliminating the necessity of moving the queen first from one to the other compartment. I take it that, perhaps, this would be more liable to cause the cells to become chilled; and possibly being to one side, and, therefore, not breaking up their home so much, would cause them to be indifferent in their attention to the cells. I do not think I have misunderstood the plan, and I think I can see sufficient reason for the cells being in the center of the chamber, but wondered what experience had shown.

Salisbury, Vt.

FRANCIS J. PETERSON.

[Referring to the divided brood-chamber, on page 11 of "Modern Queen-rearing," we may say that the bees from the field have access to all compartments of the hive. Ordinarily the bees would store most of the honey around the brood where the queen was, neglecting the other side from which she is temporarily absent. Then when she is transferred over to the other side the bees will begin storing their honey where she was, and where the eggs are being laid. As a matter of fact, the workers are perfectly free to go to any portion of the hive; but the queen is confined to one side or the other.

It is much better to have the cell-building right in the center of the hive, because it must be in the warmest part. You have very largely anticipated the reason for this in supposing that the cell-building should be in the center of the hive on account of the extra protection and warmth. Then there is a further reason: If the hive were divided into two parts—one part of which was only one-third as large as the other part, and the cell-building were put on one side, the colony in the larger part would have more of the colony spirit; and as the queen would have access to all of the six combs, there would not be the same stimulus to complete the cells in the other section of the hive where there were only three frames. By dividing the hive into three equal parts, the portion where the queen is is so small that two-thirds of the hive is actually queenless; while with the other plan referred to, one-third of the hive would be queenless while the other portion would be supplied with a queen, and there would be brood in probably five or six combs. This condition would take away largely the desire to in the other portion that is separated off by means of perforated zinc.—Ed.]

Fermentation of Comb Honey Due to Continued Wet Weather

On page 705, Nov. 1, you ask some one to throw light on the question of comb honey, as asked by Mr. S. A. Fuller, Helena, Ark. This is the simplest thing in the world to diagnose. The honey was gathered with a very great surplus of water, and the bees in their rush failed to guess just when to seal it, and did it too soon. The result was fermentation. To make the matter more clear I will say that colonies short of bees during wet seasons when honey is coming in rapidly are extremely bad about sealing honey that contains too much water. I have had honey ferment in the hives so badly that actually the fermenting gases would burst the cells and cause the honey to run out. I have many times uncapped

honey that would be so badly fermented or soured that the honey in the cells would not be much more than a mass of bubbles. In practically all cases where this kind of fermentation was manifest, it was in weak colonies during wet seasons at a time when honey was coming in rapidly. A heavy rain will not cause this condition. It comes at a time when continued rains occur for days, and produce a very vigorous growth of vegetation, and when the nights are dewy. I have noticed that very great fermentation is confined to the colonies short of bees, and the fermentation decreases as the bees grow stronger, until none is noticeable in colonies that were normal or above normal. I have not had honey even taste of fermentation for four years, which is due to the dry weather conditions prevailing in Texas. I have had honey so badly affected in the combs in the hives that it had to be thrown away. It was not fit to eat and not fit to give the bees.

Bartlett, Texas.

H. P. ROBINSON.

Laying Workers; How to Get Rid of Them

On p. 523, Aug. 15, the editor advises Mr. F. B. Fenner to break up a hive and distribute the combs among other hives in order to get rid of laying workers. I have not the slightest trouble in dealing with these pests, and my remedy is as old as the hills. If I find laying workers I take the whole hive fifty yards away, out of view of the old stand; dump all the bees on the ground and leave them there. Then I take the empty hive and bare combs, and put them back on the old stand. I give the bees two frames of young brood, and the next day a cell or a queen if I have one. I have always been successful when doing this, for the laying workers do not find their way back.

MAJOR SHALLARD.

(S. Woodburn, N. S. Wales, Sept. 9.)

[It is true that this is an old treatment for the trouble; but it is a lot of work, and one or two have reported that it failed to work.—Ed.]

Comb-building Again on an Introducing-cage

I read with pleasure the article by Mr. Bigelow, Oct. 15, page 657. I had a similar experience. I set my queen-cage between two frames; and upon going there a few days after, I found a piece of comb with eggs. I had a queenless nucleus with nothing to raise a queen from, so I took the comb from the introducing-cage, and grafted it to the side of the frame. I went to that nucleus about one month later, and found brood in all stages, with a nice young queen which had been reared from this piece of comb. I think that beekeepers had better leave all cages in for awhile, and see what next will happen.

Denies that the Honey Soured

In your issue of May 1, 1912, p. 265, you published a letter for me in which I was criticising Mr. I. Hopkins' method of extracting honey before being ripe, and ripening it by artificial means outside of the hive. In the above-mentioned letter I stated that Mr. Hopkins while in charge of the apiary in connection with our exhibition had some honey exhibited which soured. Mr. Hopkins has sent me a lawyer's letter in which he denies that there was ever any honey soured, and asks me to withdraw, or proceedings will be taken against me. As the beekeeper who told me he saw the honey, and noticed that it had gone sour, and of its sudden removal, is away in England at present, and is not expected back until December, I replied that all I could do was to write to GLEANINGS and state that Mr. Hopkins denies it.

Our Homes

A. I. ROOT

Wherefore, seeing we also are compassed about with so great a cloud of witnesses, let us lay aside every weight, and the sin which doth so easily beset us, and let us run with patience the race that is set before us.—HEB. 12:1.

Our good friend T. B. Terry, in a recent number of the *Practical Farmer*, gave the suggestion of the above text, which has a double or treble application. Read it, and see what you think of it:

CARRYING A SACK OF FLOUR ALL DAY.

How would you like to have a quarter-barrel sack of flour, 49 pounds, tied on your back and have to carry it around all day long? Do you think you could stand it? Certainly you would not feel like doing much else. But don't you know this is what a person is practically doing who weighs 50 pounds more than he or she ought to? They are carrying around 50 pounds of dead weight unnecessarily. Some people high in office may carry more dead weight than this, even up to half a barrel of flour. Isn't this a pretty good reason why they ought not to be expected to accomplish much more. Twenty years ago the writer weighed about 30 pounds more than he ought to. His wife weighed fully 50 pounds too much. One of the gains from more simple ways of living has been the reducing of our bodies to normal size. Wife weighs plenty enough now, and still she has lost fully the weight of a quarter-barrel of flour. I weigh enough, 160; ribs are well covered, smooth, and plump, and still I have got rid of 30 extra pounds. I feel truly sorry for all people who weigh from 25 to 100 pounds more than they should, and would like to help them. They are expending part of their energy carrying around dead weight that is of no earthly use to them, and which may cause death prematurely. All that is necessary to reduce one's weight is to eat a little less than the body needs to run itself. Then it has to draw on the surplus stored-up fat for fuel. Plain, simple food only helps one about doing this. Very slowly the weight can be reduced with entire safety. But it takes will power, of course. Every pound of surplus fat laid on the body first went into the mouth as surplus food, extra beyond the amount needed to run the body well at normal weight. The body should be plump, well covered with flesh, but no more, to get most out of life.

Now, this is really a vital matter. I have good kind friends, and so have you; they are all around us, who are carrying such a burden as he describes, every day of their lives. I think it is true that these men or women who weigh 200 lbs. or more have more strength and muscle than some of us lighter ones, or else they would not be able to do any kind of work profitably, so handicapped with excessive flesh. This matter has already received much thought, and has caused a good deal of worry. We have proof of it in the anti-fat remedies and drugs advertised; and it has often been suggested that we cut down this superfluity of flesh by a more abstemious diet. I have talked with several friends in regard to the matter, and they claimed that keeping

hungry all the time does not help the matter very much, and I think a few have suggested that it made them fatter still. Now, a little surplus flesh or fat, whichever you may term it, is a pretty good thing. Witness Dr. Tanner's experiments described on page 497, Aug. 1st; and I might add also, what I have mentioned several times already. At one time in my life, in search of health I lived for eighteen weeks on ground lean meat—mostly beef-steak. I think that, when I started in, I weighed something like 135 lbs. At the end of the experiment I was down to about 112 lbs., and in this shape I could ride a wheel like a boy of fifteen. But it was quite imperative for me to have my beef-steak rations pretty regularly three times a day. The most that I craved during those eighteen weeks was ripe juicy apples. In fact, I lay awake night thinking how much I would give to have the privilege of climbing over into the orchard and helping myself as I used to do when I was a boy; and I think my good friend Dr. Salisbury made a mistake in saying that apples would harm me.

I am satisfied, as I have said several times before, that a great many people would get relief from their digestive troubles by taking up the lean-meat diet or sticking very closely to it, cutting off all sweets, unless it is such as are found in natural fruit. Well, it has been proved many times over (remember what I have quoted from Upton Sinclair) that one who is in a fair state of flesh can live not only days but weeks without any food at all, but using plenty of water, of course. It requires self-control, I am well aware; but what is a man in this world of ours who exercises no control over his appetite and animal passions? A great many times I think that cutting off sugar alone would relieve obesity; and, by the way, it would also cut off a lot of low passions and desires, as I know by experience. It always worries me when I see people putting heaping spoonfuls of sugar, or two or three of them, in a cup of coffee. The sugar in some other shape would not be as bad. A combination of hot water, with sugar enough just right to produce fermentation, and make "beer" in the intestines, is what causes a lot of complicated diseases. The superintendent of a great railway was troubled with terrible headaches. He went to a sensible doctor who, after questioning him about his habits, said, "You just stop

putting sugar into the coffee you drink three times a day, and at the same time abstain from using sugar in other ways, and then let me know if you are not all right." He followed the doctor's advice, and his headaches entirely disappeared.

I am sure Terry is right where he says that when you reduce the amount of food sufficiently your system will draw on the stored-up fat. At any rate I have twice proved this conclusively by the starvation cure. Plain simple food, without too great a variety, will do the same thing. It is the pie and cake and ice-cream, and perhaps nuts and fruit after we have *already* had a good square meal, that cause our troubles. The women-folks are largely responsible for this. I am begging Mrs. Root almost constantly to give us two less variety in our breakfast and dinner. Of course the table does not show off with so little on it, and, besides, it is not the fashion.

I recently saw a newspaper clipping to the effect that our Department of Agriculture, I think it was, appointed a commission of eight men and eight ladies, sixteen in all, to discuss the matter of the "high cost of living" and to provide a remedy. Well, in order to have a pleasant time while they transacted the important business they had a lunch. I presume that we who pay the taxes paid the expense of that "lunch." What do you suppose the bill of fare was for that crowd of sixteen? Well, it came to \$160, or about that, or \$10.00 for each plate while they discussed the *high cost of living*. I have suggested already in my former paper that the high cost of living does not need to trouble farmers very much if at all; but I forgot at the time that the farmers have to pay the taxes in order to provide lunches for some of our fashionable friends who hold important offices, at the rate of *ten dollars a plate*.

Terry suggests that it takes *will* power to stop eating when you are still ravenously hungry. Now you know, dear friends, I do not want to boast; but an illustration comes in right here. When I was between twelve and sixteen I had got hold of the vegetarian hobby. I was for four years so much of a vegetarian that I would not eat any chicken when we people on the farm had a "chicken dinner;" so you see I have pretty well tested a pure vegetarian diet and also a pure-meat diet; and my conclusion is that the great Father, in his merciful kindness and wisdom, has made us so that we can adapt ourselves to a great variety of food, or we might say to a wide condition of things. When some of

the family were once laughing at me about my vegetarian hobby a good kind friend who has been a friend to me through long years said something like this :

"Now, since you are making so much sport over our friend Amos and his notions, as you call them, I wish to say to you that I should be exceedingly glad if I could hold my own appetite and desires in such perfect control as that boy does. Very likely he will some time get over his vegetarian notions; but this habit he is forming in his early youth, of being able to control himself in these things where great men give way, will enable him to make his mark sooner or later."

Now, this friend's words have proven true—at least in a measure. But they would *not* have proven true had I not ultimately gotten hold of the strong arm of the Lord Jesus Christ. When I came to the point where I was obliged to admit that Satan was too much for me I would have *gone down* had it not been for my good mother's early teachings which prompted me to say as did poor Peter, "Lord, save or I perish."

Dear friends, T. B. Terry, when he talked about that sack of flour strapped to a man's back made a very happy illustration. I am tempted to laugh whenever I think of it; but do you not remember in reading in Pilgrim's Progress years ago (I hope you are reading it now once in a while at least) the picture of poor Christian toiling laboriously up a steep hill with a great burden strapped over his shoulders? I suppose he was wiping the sweat from his brow as he toiled along in that difficult uphill path. You may remember, too, how he came to a point where the burden tumbled off and went down into the "bottomless pit." His friend Evangelist touched the iron bands that Christian in his own strength could never have loosened; and the burden that had handicapped him for so many years was gone in an instant. Fifty pounds or more of useless flesh is a sad thing to carry through life! but, oh dear me! what is that compared with a load of guilt that many of us shoulder day by day, and can not, or imagine we can not, shake off? The papers have told us of a man who was guilty of murder. He escaped; but somebody else—an innocent man—*was sent* to prison for life for the deed. After many years had passed, and the guilty man was facing death, he confessed his crime, and the poor innocent man was set free. What sort of load did that guilty

man have to carry? I told you a few issues back of how much I was enjoying the presence of the Holy Spirit until I grieved it so it went away. A guilty conscience so burdened me that I could neither eat nor sleep until I got rid of that burden.

Our management has just asked how many there now are who took GLEANINGS at the time it was printed by windmill power. Huber tells me that we have letters from something more than fifty. These veterans who have stood by us all these years will remember the time when I knelt down in the darkness—spiritual darkness as well as real darkness—and asked God (if there was a God) to give me back the innocence and happiness of childhood, and how, down on my knees, I promised the great Father to give up all and every thing that I possessed, even life itself, to be freed from the burden of sin that was daily getting to be more and more burdensome. The prayer was answered, and with trembling footsteps I started out to explore the new heavens and a new earth; and it was then and there that these Home papers were started. God knows how soon or where the end shall come, or who shall take them up when I am called on to lay down my labors here on earth.

Perhaps we may consider how it is that men and women consent to handicap themselves with a surplus of *avoirduois* equal to a sack of flour or even more. It may not be easy to say just what brings this about. If we should hastily decide that it was due to overeating, it might sound a little tough and severe on some of our feminine friends who happen to be "plump" as well as "rosy." It is bad, without question, to be overburdened with flesh; but, my dear friends, it is worse to have a burden imposed on us by giving way to sinful temptations; and not only give way, but *invite* sinful thoughts and actions. The tobacco habit is a burden, as I think all must admit; but intemperance is a greater burden, and generally an additional one. Not only is it a burden on the shoulders of the wretched victim himself, but a burden on the wives and children who often go hungry, and lack in flesh as much as the others we have been considering are oversupplied. Tobacco and drink not only impose a burden but a constantly increasing burden. There is no need of denying it, for we see it all about us. Why should a boy in his teens invite such a burden—a burden not only on his body but on his finances?

Let me illustrate the difficulty of once

getting rid of the burden of tobacco habit. A good friend of mine at one of the Michigan beekeepers' conventions told me of being helped by these Home papers, and then he gave this illustration: He had been teaching a class of boys in Sunday-school, but he was a user of tobacco, and he very soon saw he would have to give up tobacco or give up his class. What should he do? He said he had thought it over, and prayed over it; and finally he decided that he could not stand before that row of bright young faces as a spiritual teacher while he knew, and *they* knew that he used tobacco. He prayed for grace to give up the tobacco, and rejoiced in the liberty and happiness he had found in breaking off the habit for Christ's sake. Two of his sons stood near me while he told the story, and they were not tobacco-users, and rejoiced to see that their father was emancipated from a habit contracted years before—perhaps when *he* was a boy.

Now, I should be glad to end my little story right here. Years afterward, when I met him again, I found he had given up his class in Sunday-school, and gone back into slavery, to the tyrant Habit. Now comes the *saddest* part of the story. He held on to his class, and kept his pledge faithfully for *three* full years, and *then* went back. We want to realize how big a job it is to get rid of this burden of bad habits and not have them come back.

In the 7th chapter of Mark, verses 21 and 22, there is a list of sins that burden poor infirm humanity: "Evil thoughts, adulteries, fornication, murders, thefts, covetousness, wickedness, deceit, lasciviousness, evil eye, blasphemy, pride, foolishness." The next verse, the 23d, explains how we come to shoulder such filthy and disgraceful burdens. "All of these things come from within and defile the man." You see it is all our own fault. We permit these foul weeds to take root and grow; and they do not grow, mind you, without encouragement, just as the crops in our garden do not grow without encouragement.

A great deal is being said in the papers of late in regard to the high cost of living. A recent issue of *Green's Fruit Grower* tells us how a large part of this burden is needless. Read it:

HIGH COST OF LIVING.

"There are in the United States 10,000 men who are making and distributing liquor." This great army is responsible for the high cost of living. Here are 5,000,000 men, women, and children dependent upon the liquor business. Who feeds them? The laboring man who last year turned over \$1,000,000 to them; who divided the loaf that should have gone to his family with the

families of the liquor men. Then there are 200,000 non-producers in the jails and penitentiaries of the country, brought there by liquor. Who feeds them? The overburdened taxpayers. Then there are the men engaged in maintaining the courts and prisons and patrolling the streets to keep the influences of the liquor traffic within decent bounds which, with the idle rich, often made criminal by red wine, make up 5,000,000 more. Then there is another side to the problem. Last year the population of the United States increased 21 per cent, but the production of beef cattle only 3 per cent, and this because 106,000,000 bushels of grain that should have been fed to the cattle of the country went toward making liquor.

If this could have been applied to its proper

uses the cattle would have increased 21 per cent, and the price of beef been lower.

I must confess that I did not realize before how the liquor-traffic throws burdens on the shoulders of each and all of us because we permit it to go on, as well as on the shoulders of drinking-men and their suffering families.

Wherefore, seeing we also are compassed about with so great a cloud of witnesses, let us lay aside every weight, and the sin which doth so easily beset us, and let us run with patience the race that is set before us.—HEB. 12:1.

Poultry Department

"FORECASTING THE LAYING HEN;" OR, SELECTING FROM THE FLOCK THE BEST LAYERS.

On page 675, Oct. 15, I suggested that Lady Showyou did not perform her great stunt according to Mr. Leonard's philosophy or system; but it looks just now as if I owed him an apology; for he says the reason she laid an egg so regularly at about the same hour every morning until she came near a "skip-day" was that, to follow his rule or discovery, she would have to drop her egg in the night; and, like most prudent hens, instead of doing this, and causing breakage and loss, she decided to hold the complete egg in her ovary until daylight permitted her to deposit it in her regular nest in an orderly and orthodox manner. See what he says about it below:

Mr. A. I. Root:—I wish to make a correction, and a few remarks on Lady Showyou's record in GLEANINGS for Oct. 15.

Her record for March was 29 eggs in place of 20, as you have it. She also laid 29 eggs in August—in fact, she laid 29 eggs for each month, March, April, June, July, August, and 31 in May.

In GLEANINGS you made no mention of the fact that this hen was in the egg contest in Missouri, or that she was but one of many laying nearly as well, and having *but one skip-day*, as I claim they must have; but in place of quoting her as corroborative of my claim, you use her as an example in proof against it.

You cite her as a 24-hour hen laying an egg daily, laying *occasionally* a little later each day until they skip, and do not recognize that her skips come regularly, and can not, therefore, be accidental nor even *occasional*, but must be due to some law.

Now, I wish to go on record as stating that this hen is a 25.24 hours *ovary interval* hen, that meaning that she requires 25 hours and 24 minutes in which to create an egg.

She should lay 23 eggs between her skipdays in the months she lays 29 eggs, and she lays at 8 A. M. all of her eggs except three or four, because they come due the night before they are laid.

A hen that has an ovary interval of 25 hours must have eggs due one hour later daily; and counting from 2 P. M. they would be due at 3, 4, 5, 6, 7, 8, 9, 10, 11, 12 P. M., and 1, 2, 3, 4, 5, 6,

7, 8 A. M., making 18 eggs due too late to be laid, and so held over until morning, and the three reported as laid scattering, totals 21; but as there were five to be laid scattering, there are two eggs carried over to be added to those laid before 8 A. M., so the actuality is 20 eggs laid before 1 A. M., and three eggs laid scattering—total 23, before a skip.

However, this is not the way I get at it. I find the hours in 31 days to be 744, and divide by her ovary interval, which gives 25.744 (= 29 eggs with a fraction of 19-25, which allows for the 24 minutes of her ovary intervals.

For ten months' laying there were 14 hens which laid 200 eggs or more, out of a total of 655 hens.

There were but two hens that laid better than my No. 1 in 9 months. There were but nine that laid better than my No. 2 in nine months. There were but ten that laid better than No. 2 in ten months.

My No. 2 has just finished two years' laying with 381 eggs.

My No. 1 laid, in her first two years' laying, 385 eggs.

These two hens have the same ovary intervals, and lay in the same manner.

There were ninety-two hens that laid 20 eggs or better in July contest. These hens were in the 36-hour ovary-interval class, or *better*, and skipped *but one day*.

These are the only kinds of hens I keep myself, and my claim is to be able to find them quickly.

There are hens in this contest that have never laid an egg, and others that have laid very few; and there is no *pen* that has done what it would had they been previously classified according to ovary interval.

Pen No. 28 (Brown Leghorns) laid in July as follows:

25, 21, 21, 23, 22; total, 114 eggs.

Pen No. 20 (White Leghorns), 23, 25, 23, 24, 22; 117 eggs.

Pen No. 13 (White Leghorns), 25, 15, 24, 30, 25; 119 eggs.

Many other pens could have made good records but for some poor individual. Many pens have one or two good layers, and the rest poor ones which cut down the total. By classifying as I suggest, many good pens could be made and the record beaten greatly.

Hens of 28-hour-ovary intervals or less lay like Lady Showyou. Below 28 hours their eggs fall a certain number of hours apart, according to their class.

Whenever the daily loss does not divide into the hours of any period of days evenly, the number of eggs to a cycle will vary to average up.

I am getting out mimeographed copies for publication, and expect there will be at least ten sheets the size of this—8 x 12.

I shall also offer my services to poultrymen who wish me to classify their hens into pens of the same laying ability. This is what you asked me if I could do, and I propose doing it. I have shown many, who say it is easy. A man came over from Jacksonville who is to start a large farm, and I shall either classify his hens or instruct him how to do so.

C. W. LEONARD.

St. Augustine, Fla., Oct. 30.

Surely our experiment stations, and those who have charge of the egg-laying contests now going on, can decide whether he is right; and if so, it looks as if he really *had* discovered something we had overlooked, or which was unknown until the present time. Can not somebody who is in daily practice with trap nests enlighten us?

INFERTILE EGGS; CAN THEY BE SORTED OUT BEFORE BEING PUT INTO THE INCUBATOR?

Some time back I said that competent men of experience had decided that no secrets or machine could tell any thing about the fertility of eggs before being given to a hen or incubator. One of our friends suggests that my position may be misleading, and submits the following:

In every lot of eggs taken from a breeding-pen there is a percentage unsuitable for hatching, or, rather, for using for hatching purposes. An experienced and competent man can set aside a part of this percentage simply by examining the eggs as he lifts them from the gathering-basket; but the other part of the percentage can be discovered only by candling—an acquirement which can be gained only by practical experience. If there is a small percentage of useless eggs in a well-kept breeding-pen, there will frequently be a large percentage in a flock kept as the ordinary farmer has his hens. This percentage often runs as high as forty, but say twenty-five. In most cases these twenty-five eggs are wasted! or if some of them do hatch they are worse than wasted by producing weakly or sickly chicks. If the farmer could avoid this loss, the advantage would be considerable in many ways. Last year the writer had charge of a poultry-plant where the stock had up to the time he took hold been abused in nearly every conceivable way. On arrival he found the incubators giving 70 per cent fertility, and of this 70 per cent about three-quarters produced living chicks. The hatching eggs were at once taken in hand, but without pre-incubating testing (for want of time), and the eggs then showed 80 per cent fertility. For the next hatches the eggs were carefully tested before being put in the machines, the result being 90 per cent fertility.

The specific gravity of an egg is no proof whatever that it is fertile or unfertile. The only way to know whether an egg is fertile or not is to break it and use a microscope on the contents. But pre-testing by a competent person usually gives results that more than pay for the time and labor.

Philadelphia, Pa., Aug. 14. FRED MARTIN.

Friend M., I agree that an experienced man or woman may sort out by the looks eggs that are more likely to be fertile; and perhaps the use of a candle or egg-tester may help a little, especially if the eggs are taken from a miscellaneous collection. Old eggs can be sorted out from

the fresh ones by means of an egg-tester. Some time ago my neighbor Abbott wanted me to save him some eggs for his incubator. I charged him only the price I received at the grocery; so he took the liberty of sorting out the best in the lot. He threw out under-sized eggs, crooked eggs, eggs with heavy shells, or those with wrinkles on the shells, and this secured a lot of nice-looking uniform-shaped eggs. There is no question but that such a course will pay. As you say, specific gravity has little or nothing to do with it; and yet the fellows who advertise this machine at a big price have the audacity to put in print that they have never had a magic egg-tester returned. I returned the one they sent me, and wrote it up on these pages.

In regard to the concluding sentence, I very much doubt whether a microscope would distinguish the germ before the egg has commenced incubation. Will somebody who has tested this matter let us know about it? Of course, this would accomplish nothing; but it would upset the claims of some of the swindlers who profess to be able to pick out the fertile eggs before they are put into the incubator. Why not put in as many eggs as you can by standing them on the small end in the incubator, and then throw out the infertiles in three or four days?

DOCTORING CHICKENS.

The following, from such excellent authority, we clip from the *Southern Fancier*:

"Poultry doctor" is not a profession—it is a mistake. There is no need of medical science in the poultry yard. Good methods and good common sense are better medicines than drugs.

Now, in addition to the above I want to give you something clipped from the *Rural New-Yorker*:

When you wish to tell your poultry-raisers how to save money I will tell you how to do it. A useful article, being a disinfectant that can be used in drink to help ward off parasitic disease, is germozone. It is sold at 50 cents for about an eight-ounce bottle. Mistrusting from appearances what it was, I had it analyzed at the Connecticut Agricultural College department of chemistry, and they found it to contain a small quantity of permanganate of potash and a little alum, the rest being ordinary water. All the drugs in it would not be the value of one cent, the other 49 cents being charged for the water and the bottle. The same preparation may be prepared by any one by using one part permanganate of potash to one thousand parts of water (this germozone was somewhat less when used per directions), and a little bit of alum added. It is useful in roup, diarrhoea from germ infection, etc.

Massachusetts.

A. E. C. L.

The germicide mentioned in the above has been advertised for a year or two past in nearly all of our poultry journals. No

doubt it does some good; but just think of it! It costs 50 cts. a bottle, and yet the real medicine contained in it costs *less than one cent.* And this is a fair sample of the

fifty-cent remedies we find advertised in almost all poultry literature. Is it not about time for a revelation or a revolution or something else in the poultry business?

Temperance

PROHIBITION DOES PROHIBIT.

Not only our great railways, but the great banks of our nation, are demanding that their employees shall not enter saloons. The following item, which we take from the *Home and State*, Dallas, Texas, indicates the trend of business:

About two thousand years ago the old Devil himself started on old lie to the effect that a young man could take a drink of whisky or let it alone, and it would not hurt him. The old lie has been repeated all down the ages until many sensible men seem to believe that it can be done.

To answer that old lie, and seeing the necessity for protection against it, not long ago the Fifth Avenue National Bank of New York passed some stringent rules governing their employees, and some of those rules read as follows:

"You must not drink any intoxicants with meals in public restaurants." "You must not enter any saloon." "You must not enter any gambling house." "You must not frequent Broadway resorts or become conspicuous where the great white lights blaze."

The National Bank of Commerce of St. Louis, one of the largest national banks in all the Southwest, having 330 employees, recently passed similar resolutions governing their employees, and the National Bank of Commerce went further and said: "The use of cigarettes will not be tolerated under any circumstances." "Late hours, the habitual use of intoxicating drinks, the frequenting of saloons and questionable resorts, will be deemed sufficient cause for dismissal."

When some twenty sane and sound business men gathered around the directors' table and passed those rules, none of you would look into their faces and say they were a group of prohibition cranks, but on the other hand you would say that they were taking the sensible way of answering that old black lie that a young man can take a drink or let it alone and it will not hurt him; and you will let me add to those rules, and say with all the love and all the force I have, that the old lie that a young man can take a drink of whisky and it will not hurt him is the blackest old slimy lie that was ever told.

I must confess that it is a surprise to me to be told that any city *bank* has as many as 330 employees; and may the Lord be praised for the information that not one of the 330 is *permitted* to use cigarettes.

WHISKY AND BRANDY IN CANDY FOR CHILDREN.

We clip the following from the *Nashville Tennessean and American*:

MAKING WAR ON WHISKY CANDY.

Dr. Lucas P. Brown, State pure food and drug inspector, having discovered that certain candy-makers are putting whiskies and brandies in a special brand of candies which they have put on the market, has inaugurated a vigorous war on the practice, and, despite the fact that the grand jury

of Shelby County threw out the suits brought against these candy-dealers, he says there will be no backward step in the prosecution of the law-breakers.

Upon finding that candy of this kind was being sold in Nashville, Dr. Brown let it be known that such sales were unlawful and would not be tolerated, whereupon the dealers adopted the wise course of refusing to deal longer in such wares. It was enough for the Nashville dealers to be apprised of the fact that such violations of the law would be prosecuted, for they at once advised Dr. Brown that they would not again be guilty of the offense.

"The practice of putting brandy and whisky in candies, thus cultivating a taste for liquor among our little boys and girls," Dr. Brown says, "must stop, and I believe that there is strong public sentiment back of me in this campaign for the stopping of such practices."

I remember hearing some time ago that there was brandied candy on the market, and that children were buying it; but I supposed the business of making and selling such candies had been stopped. Our southern States that have been so vigorous in ruling out the liquor traffic should certainly be wide awake in putting a speedy stop to this sort of business.

ONE HUNDRED THOUSAND DOLLARS CONTRIBUTED BY A SINGLE BREWERY TO FIGHT PROHIBITION.

We clip the following from a recent issue of the *Independent Magazine*:

A lawsuit brings out the extraordinary fact that a single brewery in Worcester, Mass., certainly not one of the largest, has spent \$100,000 in the last ten years in political contributions to fight prohibition. Just as Congress is conducting an investigation on contributions for presidential campaigns, it would be well if every State legislature should order an investigation of the sums contributed to prevent the enactment of laws suppressing the liquor traffic. They must amount to many millions, largely spent in corrupting the electorate.

Things like the above seem to be coming to light almost daily; and yet what are we as a nation doing about it, or are *going* to do about it? What are the churches, the Christian people, and the temperance people doing or going to do about it? Is money, and dirty "tainted" money, going to continue to head off the votes of good men and good *women*?

A GOOD MOTHER—WHAT IS SHE WORTH?

I read *Our Homes* first, then the temperance column. I never drank a glass of liquor in my life nor used tobacco in any form. I thank God for a good mother.

NO. 24

Editorial

THE AMERICAN BEE JOURNAL.

WE are pleased to note the evident progress in the growth of the *American Bee Journal*; it is also a pleasure to see an occasional article from the pen of our old friend Geo. W. York, now of Sandpoint, Idaho. Mr. York was editor of the *American Bee Journal*, it will be remembered, for twenty years. While he has since gone into other business, he still retains his interest in bees, and is starting an apiary in a land that gives promise of being a great bee country in the near future.

THE OHIO STATE BEEKEEPERS' CONVENTION.

WE would call attention again to the Ohio State Beekeepers' convention that is to be held in Columbus on the 14th and 15th of January next. Secretary Shaw submits a tentative program which we are pleased to insert right here.

PROGRAM TUESDAY, 2 P. M.

President's Address.

Report of Treasurer.

Report of Secretary.

Result of Apiary Inspection in Hamilton County
Fred W. Muth
With the Apiary Exhibit at County Fairs.....
Glenwood Beard

TUESDAY, 7:30 P. M.

Apiculture at the University.....

Prof. J. S. Hine, Ohio State University

Address—Organization.....E. B. Tyrrell,

Secretary National Beekeepers' Association

Address—C. P. Dadant, Editor *American Bee*

Journal

Live-bee Demonstration.....E. R. Root,

Editor GLEANINGS IN BEE CULTURE.

WEDNESDAY, 9:30 A. M.

Florida Beekeeping.....J. E. Marchant

Queen-rearing.....J. C. Mosgrove

My Experience with European Foul Brood.....

B. J. Holden

Ohio Apiculture—Impressions of a Farmers' In-

stitute Lecturer.....Prof. W. A. Matheny,

Ohio State University

WEDNESDAY, 1 P. M.

A Woman's Way with Bees...Mrs. Jessie Goodrich

Wax Rendering.....H. H. Root

Production of Comb Honey.....A. A. Doenges

Production of Extracted Honey.....H. G. Quirin

Topics for General Discussion

So far as we know, all the speakers assigned have promised to be present or send in papers. The convention will be held at Townsend Hall at the State University. It is expected that there will be from one to two hundred short-course agricultural stu-

dents present at the meetings. This will ensure the largest bee convention the good old Buckeye State has ever had.

A SURE CURE FOR SPRING DWINDLING; HOW THE SCHEME OF POUND AND HALF- POUND PACKAGES OF BEES CAN SOLVE THE PROBLEM OF THE NORTHERN BEEKEEPER.

IN our last issue, on page 752, we mentioned the success we were having in shipping bees by the pound all over the United States with practically no loss. If others can be as successful as we have been (and we see no reason why they can not be after we show them how) it will be possible for one beekeeper in a locality in the South to supply a brother beekeeper in the North with 2-lb., 1-lb., or ½-lb. packages of bees for his weak or dwindling colonies, that he may have on hand, in the spring. Some colonies might need 2 lbs. of bees, others only 1 lb. or ½ lb. The problem has been, however, to find some one who could supply bees in pound packages *early enough* to meet this kind of demand. We have been having considerable correspondence with Mr. A. B. Marchant, of Sumatra, Fla., now temporarily at Appalachicola, covering the question of whether he could supply bees in this way during February, March, and April to those in the North who have spring dwindling. Mr. Marchant thinks he can take care of all who may desire bees in this form as he has an immense stock to draw from. Prices and particulars will be announced later.

If this scheme of sending pound packages of bees from the South to the North can be made a success it will enable the Northern man to save hundreds of valuable queens, and put new strength and vigor into nuclei that would otherwise struggle along all summer without furnishing any surplus. We see no reason why pound packages of *black* bees could not be sent northward at a reduced price. They would be just as good boosters as the more expensive bees.

RIPENING HONEY ARTIFICIALLY; WHY WE DO NOT RECOMMEND IT FOR THE AVERAGE BEEKEEPER.

We call attention to a most excellent article by Mr. Isaac Hopkins, p. 801, of this issue, on this subject. While we believe that the average beekeeper and all beginners should not attempt to ripen artificially, we are convinced that Mr. Hopkins knows how to do it; and there are doubtless other experts who have been able to do so. We hesitate to give countenance to the method because of its tendency to induce carelessness on the part of many extracted-honey producers, in that they will extract before the honey is thoroughly ripened, assuming that the process will be finished in open vats screened from bees. Too many times in this climate the humidity of the atmosphere is such that such exposed honey, so far from evaporating out the excess of water, takes up more of it. It is this condition of atmosphere that is responsible for the poor quality of some of the artificially ripened honey on the market. Such honey when put into cans and barrels causes no end of trouble. The honey ferments, causes a pressure until the cans burst, and the barrels shoot their bungs out like the shot of a gun. The honey then boils over, soiling every thing. In a damp atmosphere bees can ripen their honey while man fails.

When the late Mr. Alexander advocated ripening honey artificially he was roundly scored by honey merchants and beekeepers alike, and we were severely condemned for publishing the matter in the first place.

If all beekeepers were as careful as Mr. Hopkins, and if all of them would use a hydrometer to test the specific gravity of the honey before it is sent to market, there might not be so much objection to the process of artificial ripening. By the way, the hydrometer is something that every extracted-honey producer ought to have; for it transpires that some bee-ripened honey is not as thick as it should be.

GIVING A COLONY HAVING A VIRGIN, EGGS TO HASTEN HER EGG-LAYING.

REFERRING to the discussion on page 796 of this issue between the two Millers, we beg to butt in again—even if we do get smashed between two such heavy weights—especially so as one of the contestants says, “I will turn my attention to E. R. He is sitting as a judge, but I will make him co-defendant.” In the first place, we may say we are of the same opinion still as expressed on page 708, Nov. 15, namely, that we have “never been able to discover that the

giving of eggs and larvæ had any thing to do with hastening the demise of a virgin queen;” also that Mr. Pritchard “makes it a practice to give colonies with virgins young brood.” Notice in the second quotation that we are talking about *colonies* and not *nuclei*. As a matter of fact we do not make it a practice to give nuclei eggs and larvæ to stimulate their virgins to laying. As A. C. Miller points out it would be too expensive, and take too much time. In the second place, we did not abandon our baby nuclei as we had intended. Early in the season we did think (see page 326) that full-size-frame Langstroth nuclei would be better than our twin baby nuclei; but a further and much more prolonged test during this season has convinced Mr. Pritchard that the babies more than hold their own. We did not propose to abandon them (see page 327) as Mr. Miller implies, because of a “loss of queens,” nor because we had to give them eggs, but rather because we thought, all things considered, the larger full-sized nuclei would raise queens just as cheap or cheaper (see page 326). But on this point our Mr. Pritchard changed his mind before the season was over. We have been testing out these baby nuclei in lots of 300 at a time. We tried out 200 of the full-sized Langstroth-frame nuclei alongside of about 300 of the small ones. The little ones showed their superiority in more ways than one.

Yes, Mr. Pritchard is a man who keeps tab on everything he does. He has to or he could not keep up with orders. When we ask him for an opinion on a certain queen-rearing proposition he proves his statement by his records. These records, in connection with raising nearly 3000 queens in a season, were the basis of the statement on page 718, which we quoted above at the head of the editorial.

We may say further that Mr. Pritchard explains that he does not give the baby nuclei eggs or larvæ, for the simple reason that they do not need them. The laying queens just taken out of them he says leave no deficiency of either at the time new virgins are put in to take their place. These larger-sized twin-baby nuclei maintain their strength fairly well throughout the season. It is only the small-sized ones such as Mr. Pratt used that “peter out.”

RETROSPECT FOR THE YEAR 1912.

HARDLY had the new year been launched when most severe winter weather set in. The mercury began to drop, drop, clear down, and beekeepers everywhere were hoping and confidently expecting there would be a let-

up; but there was no let-up—at least for a very long period in most of the Northern States. The severe cold continued clear up into spring; and not until late spring did the beekeepers over the country realize that the winter of 1911 and '12 was the most severe ever experienced since the winter of 1881 and '82. Then, as this year, most colonies managed to pull through to the beginning of spring, but in a weakened condition. When the changeable spring weather came on, spring dwindling of the worst kind did its deadly work, so that the winter of 1911 and '12 and the following spring caused the greatest mortality among bees that has been known for thirty years. It was indeed a severe blow to the industry; but, fortunately for the bees and their owners, the following summer was a good honey year in most localities of the Northern States at least. Bees have a wonderfully recuperative power; and in spite of the fact that two-thirds of them were lost in many localities, and even 75 to 90 per cent in others, they quickly recovered themselves, so that now, as we are about to embark in 1913, we find practically all the bees replaced. Strangely enough, after the severe winter, clovers made a most wonderful growth, and well they might, because the summer of 1912 had an abundance of rain all over the country. Automobile men everywhere kicked about the bad roads, and everybody was complaining of a lack of dependable weather. Contractors were unable to complete their jobs on time. But this *very condition* made a wonderful growth in all the clovers. Unless untoward conditions prevail during the next six months, 1913 will witness the greatest yield of clover that has been known in many a year. There is no question but that 1912 would have produced the greatest crop of Eastern honey known in history had it not been for the fact that the number of bees to gather it was away below the average. But in spite of the few bees, 1912 will record a larger yield of *clover* honey than for many years. Not all parts of the West and South, however, fared as well as the clover belt, so that the total aggregate of honey of all kinds will be only slightly in excess of an average year.

The year 1911 took away such men as Mr. Hutchinson, Heddon, Hilton, Hall, and Herlong—all stars in the apicultural firmament; and 1912 has likewise taken four other stars—John S. Harbison, John G. Corey, both of the western coast, and R. L. Taylor, of Michigan, and S. T. Pettit, of Ontario.

The year 1912 has witnessed the change of

ownership of the *American Bee Journal*; and those of our subscribers who are also readers of that publication will not fail to note its strong and healthy growth. The Dadants are to be congratulated. The *Beekeepers' Review* is now the official organ of the National Beekeepers' Association, with a corps of editors and contributors that should and doubtless will make the *Review* a great help to the organization it fosters. The year has not been marked by any great inventions or methods of management; but there has been a healthy development, showing that the industry is being put more and more on a solid foundation. The don't-care, don't-read-bee-papers type of beekeepers are dropping out. What have not been put out of business by bee diseases have been eliminated by winter losses. In their places have come the enthusiastic amateurs from the agricultural and professional ranks, and also the specialist beekeepers. More and more we see a disposition on the part of many to keep bees on a large scale. Extractors are now being made in much larger sizes than formerly. Power-driven machines are taking the place of those driven by hand; honey-pumps and steam uncapping-knives are demonstrating their superiority over the old ways.

More attention is being given to the marketing of honey. The tendency to drop the production of comb honey entirely has been checked, and now we find more comb-honey producers producing a little extracted, and more extracted-honey producers producing a little comb honey. 'Tis well.

The amount of white clover in the soil all over the United States shows that 1913 is going to deal kindly with us providing we have nothing more than an average winter. As it is seldom that one severe winter follows another, we have every reason to think that 1913 will let us have our bees and our honey.

The year 1912 has seen the publication of a larger number of free bulletins on bees, both State and National, than usual. The Bureau of Entomology, Washington, D. C., for example, has sent out a large number on various phases of the industry. Among the States that have given us complete books on bees, for free distribution, are Massachusetts, Pennsylvania, and Texas, as well as Ontario, Canada. Apicultural schools are growing and developing, both in this country and Canada, so that we now have at least four universities that have complete courses in apiculture, and a score or more that give more or less prominence to bee culture in connection with their general agricultural courses.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

KARL MIKA, *Deutsche Imker*, 321, claims great increase of surplus from keeping bees under glass, as in a greenhouse.

FAIRNESS requires, after having written that Straw, p. 754, about the trouble with too thick glass in shipping cases, that I should report that, since writing it, I've glassed some 400 safety cases without meeting a glass thick enough to ruffle my temper. After the years of struggling I've had, what a delight it was!

GLEANINGS is quoted in *Deutsche Bzcht.*, Oct. 1, as saying the best place to have combs built out is in a super over a strong colony. Dr. Herter approves, emphasizing the strength of the colony, and adding that the colony must be in the humor for building, when it will build just as well before or behind the brood-nest as over it. (This refers to hives with combs running parallel with the entrance.)

EXACTLY how bees gather pollen has been difficult to learn because of the exceedingly rapid movement of the bees. The cinematograph has helped out. Pictures are taken in which the bees can be made to go slow enough to be easily followed.—*Leipzig. Bztg.*, 158. [Time after time we have tried to discover just how bees transfer the pollen masses from one leg to the other. To the ordinary human eye it is nothing short of a sleight-of-hand performance. We are glad to know that the cinematograph is going to show the steps of the process. If it does, GLEANINGS will be glad to illustrate them on its pages.—Ed.]

A TEMPERATURE of 32 to 35 degrees would be considered ideal for outdoor wintering, even if there was no flight for four or five months. Now why shouldn't Elmer Hutchinson's bees stand it just as well in the cellar, *provided the air is just as good*? [We assent to the last sentence; but we have not yet seen the cellar where the ventilation was as good inside as outdoors. With perfect ventilation and a dry atmosphere, bees will undoubtedly stand a lower temperature than where the air is bad, and laden with moisture. Even human beings suffer more severely in a damp and chilly atmosphere than they do in a dry cold air.—Ed.]

ALARM is expressed, *Leipzig. Bztg.*, 150, over a new danger to German beekeeping. In certain localities all the field-bees are lost in a short time. In the same localities poison-sprays are used upon mustard in bloom. [Sometimes these poison sprays are

destructive to bee life, and at other times, apparently, they have no effect. The spraying of fruit-trees when in bloom is undoubtedly destructive to bees sometimes; but it is equally apparent that it is not always destructive. Much depends on the character of the spraying liquid and the strength of it. Ordinary solutions of Paris green, so far as we can ascertain, sufficiently strong to kill the codling moth, will kill brood as well as bees. In the case under consideration it is evident that the poison spray used on mustard in bloom was strong enough to kill bees.—Ed.]

IF ENOUGH beekeepers do not work for comb honey it will not be the fault of GLEANINGS. Many a year ago I gave up the extractor, and have produced sections exclusively. Now, in spite of the exhortations of GLEANINGS I'm planning to run part of my colonies next year for extracted. For one thing, I want to learn how, and am counting on a lot of fun in the learning. [In this connection it is our belief that all comb-honey producers should produce a little extracted. Two extracting-combs in each side of the first comb-honey super put on the hive serve the double purpose of baiting the bees into sections and preventing unfinished sections in the outside rows.—Ed.]

NIKOLAUS PIRPAMER says, *Ill. Monats-blaetter*, 117, that for 30 years he has wintered nearly every year 100 colonies or more, and in that time has fed thousands of kilograms of sugar. Bees wintered well on sugar, but he noticed that colonies heavy with sugar syrup the first of October would be again light two months later, while colonies that had gathered their own stores had not lost perceptibly in weight during the same time. This is a matter worth inquiring into. [This does not seem reasonable, and we should be inclined to believe that there must be a mistake somewhere. We have never observed any thing of that sort in this locality. If any one else in any other locality has, let him speak up. Reports for many years back have shown, on the contrary, that a given amount of sugar syrup will go further than the same amount of natural stores; that is to say, the bees will consume less of them. Some honeys will cause uneasiness; and uneasiness results in a larger consumption of stores. Stores of sugar syrup, on the other hand, are always of uniform quality, and have a tendency to induce the best kind of wintering.—Ed.]

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

INFORMATION ABOUT HIVES.

As the time for buying new supplies for the coming season is at hand, inquiries about the kinds of hives to purchase, with requests for information on the advantage of divisible-brood-chamber hives have become more numerous. In connection with this matter much information is being desired about bulk comb honey and its production, so that the proper hive and super apparatus may be obtained when purchasing the new supplies. After having answered a number of them, others keep coming in; therefore the following information has been "boiled down" to hit each inquirer.

1. I would urge those who do not know what kind of hive to adopt to purchase the regular standard Langstroth ten-frame size, with shallow supers to begin with, trying only one or two divisible hives alongside of these. This is to guard against investing in something you may not find just what you thought you wanted a larger amount of money than is actually necessary to make a small trial. If the divisible hives prove all right, well and good; and if not, there are only a few of them, and they can be used as supers on the L. hives. In either case the L. hives can be more easily disposed of, as these are regular (or standard) goods.

2. The shallow frames, Hoffman style, $5\frac{3}{8}$ inches deep, with $\frac{1}{2}$ -inch top-bars, will have to be especially ordered, or frames with wide thin top-bars will be sent out by the supply dealer. The latter are somewhat weak, and sag in time, especially if grooved for foundation. This groove is not necessary with our method of fastening the foundation with melted beeswax or by any of the other most common methods used here in the South.

3. Foundation of the thin surplus kind is always used in full sheets without wires. Very few beekeepers wire these shallow frames, even for extracted honey. However, a heavier grade of foundation would have to be used if the beekeeper intends to extract from newly built combs unless a little care is exercised in extracting them the first time. After that they are tough enough to stand rougher handling.

4. No wires are ever used in these frames for bulk-comb-honey production, and thin surplus foundation is used. Extra thin is a little too light, and the bees tear it down badly.

5. All of our honey is hauled home from out-apiaries on a spring wagon—some of it for more than 20 miles. It is very seldom

that any of the combs are broken down, and very few even in the hottest summer weather.

6. In answer to the question whether it would ever become necessary or satisfactory to use more than two stories for a brood-nest when one has Carniolan bees, I would say that it is advantageous to provide just as much room as is needed for the best results with any race of bees. I find that my two apiaries of Carniolans require a larger hive, and three shallow stories are used as the main hive and brood-chamber the greater part of the season. All our normal colonies are wintered in three such stories. The upper one furnishes just that much for winter stores, lasting far into the spring, and provides extra breeding room during the spring months. It also provides storing room for the first, scattering honey, and, later, becomes a shallow extracting-super for extracted honey, which is raised up to receive the empty comb-honey super between it and the brood-chamber.

* * *

POISONING WITH ARSENATE OF LEAD.

Since cotton is a very important honey-plant in many of the Southern States, the matter of poison sprays that affect the bees of the neighborhood where spraying is done becomes a serious question for the beekeepers. The following letter illustrates the point:

Dear Friend:—I am writing for information on cotton-spraying. You always speak quite highly of cotton as a honey-plant. I get much honey from that source, but I am much worried since the people are beginning to use arsenate of lead for spraying. Two of my neighbors have lost all their bees from cotton-poisoning. Does arsenate of lead work the same in your district? Would it be better to move my bees back further into the woods? Those who lost their bees were right in the center of large poisoned cotton-fields, while mine were on the edge of the cotton district, a few rods in the woods.

Riveriera, Tex.

J. M. SAXER.

I have given this matter a good deal of attention—perhaps more because I depend almost entirely upon cotton as the chief source of nectar. In other words I would have to give up beekeeping if cotton did not yield honey in my beekeeping territory; and there are many others who will say the same about their localities. The amount of cotton honey produced is much larger than many suppose. We alone harvested about sixty thousand pounds of cotton honey this year, and bought a larger amount. It should be remembered that this was the poorest year we have had.

SIFTINGS

J. E. CRANE, Middlebury, Vt.

The bee-lines illustrated by J. Ford Semper, page 618, Oct. 1, are of exceeding interest, and shows that bees know better how to fly from one point to another better than we have supposed.

* * *

Mr. Chadwick is quite right in his recommendation of the use of burlap bags for smoker fuel, page 616, Oct. 1—nothing better. No objection if the burlap is covered with propolis.

* * *

We received a card from a beekeeper a few days ago who had some honey to sell, saying he would have sent us a sample of his honey, but he had a little foul brood among his bees, and did not wish in any way to expose our section to disease. If all were as careful we should have much less foul brood.

* * *

The yield of honey Dr. Miller secured the past season is certainly surprising, and shows the value of sticking to the business through thick and thin, and not neglecting the bees because it looks bad or discouraging. Had he not fed and cared for them until honey came I dare say he would have had a poor season.

* * *

Mr. P. C. Chadwick gives some interesting paragraphs from the Pacific coast; and while conditions are very different there from those on this side of the continent, still the fact remains that the general principles are the same, and it is the man there as here who tends his business, keeping watch as to what it is best to do, and doing his own thinking, who succeeds.

* * *

That editorial, page 503, Aug. 15, on migratory beekeeping was very interesting reading although few of us will be able to try it; but it makes one wish he were young again. To succeed, one will not only need "brains and capital" but a large amount of physical endurance as well. The building-up of a large number of colonies from a few is a trade of itself, and one which, I fear, but few of us fully understand.

* * *

Mr. Chadwick, p. 616, Oct. 1, refers to an item of mine telling how I found a very strong colony in early spring that had wintered in fine condition with a very large entrance, and thinks I have found grounds for a large winter entrance. That is not

exactly the idea. I still prefer a small winter entrance for outdoor wintering; but when I find a case like the one mentioned, where a colony has wintered in the best possible condition under conditions which I do not approve I like to speak of it, that we may all study the subject more carefully and find out the exact truth, which is vastly more important than to brace up my pet theories.

* * *

Louis H. Scholl calls for a good hive number. Say, my friend, I have one that is durable and cheap. It has been in use for more than forty years, and is good yet. Take a little boiled linseed oil and some lampblack. Mix the black with the oil rather thick, and then use with a small brush on stencil figures. I like those two inches high, so I can see them a long way off. Oh! you said you wanted figures that you could put on in a "jiffy," and change from one hive to another in the same space of time. Well, put your numbers on your covers if you want to change them.

* * *

Shipping bees in two or three pound packages, or even in larger packages, without combs or hives, is a new idea as explained on pages 645 and 649, Oct. 15. If it proves a success (as seems probable) it will be a boon to many beekeepers when, after an unusually poor season, their stock of bees is greatly reduced but their supply of combs and hives large. An extra-good season almost invariably follows a very poor one; and if one can get bees reasonably cheap he can stock up at once, and not have to melt combs into wax, and can thus be able to get not only the hives filled with bees, but surplus more than enough to pay for the bees bought.

* * *

I have about come to the conclusion that a beekeeper's education is not quite complete until he has had one or two years away from home inspecting bees. He sees and learns a great many things he has never known before or even dreamed of. A little while ago I found a colony trying to rear two larvæ in the same cell. I counted nine such cells containing each two larvæ about half grown, and they appeared to fill the cell about as full as one full-grown larva. I had supposed that two might often hatch in a cell, but supposed they were always removed when quite young. This colony was quite weak, and the total amount of

brood in the hive small. Whether the bees of this hive were trying to economize their heat and space by rearing two to the cell, or they had overlooked the fact that two had hatched in these cells I was unable to determine.

* * *

Reference is made by Dr. Miller, page 504, Aug. 15, to the dislike of bees for black stockings. Now, I believe it is the almost universal opinion that bees have a natural dislike or prejudice against black; and while it seems certain they can or will become accustomed to black, yet, considering the brevity of bee life and the value of the beekeeper's time, it does not pay to try to educate them against their natural instincts. It is better to adapt ourselves or apparel to their ideas of propriety. In this connection I am reminded that our truckman drives a white horse, and never has any fear of its getting stung when driving it near bees when going to a yard of bees for us for a load of honey.

* * *

Can bees count? Dr. Miller, page 540, Sept. 1, mentions or suggests that bees can or may tell the difference between an eight and a ten spot card. Well, perhaps they may; but I doubt much if they often do. I think I have mentioned before that a few years ago I set the hives of one yard of bees in long rows, and had a great deal of trouble in their getting mixed and losing their own hives, going into unoccupied hives in cool weather and losing their lives. When I saw what the results were I used a paint-brush freely, giving one hive a large splash on the hive front, another two or three or more, and others a circle or bar across the front, but with very unsatisfactory results until I changed the location of the hives, allowing some to enter from one direction, and others from some other point of the compass.

* * *

COLORADO GRADING RULES RATHER STRICT.

I notice on page 610, Oct. 1, a call for more comb honey in proportion to the amount of extracted honey than is now produced. I have been wondering for some time what effect the close grading would have on the production of comb honey. The Colorado rules allow but fifty unsealed cells in their lowest grade, no matter how well the section is otherwise filled. We have been told that all sections below this grade should be marketed near home; but we are not told how to sell two thousand light sections in a town of 200 population or less. Here, for instance, is a section

that weighs 13 ounces, and has 60 unsealed cells. That must be thrown out, although half the cells next to the wood are sealed on one side. Is there no demand in our larger towns for such combs? I believe there is; but if such sections must be thrown out, and the honey extracted and combs melted up, I am not surprised that so many extract their crop of honey. The Eastern grading rules are more liberal—perhaps too much so—as I doubt the wisdom of selling the ordinary size of section that would weigh but eight ounces. However, there may be a demand for such sections in some places. The desirability of nicely filled and capped sections can not be over-estimated; and the suggestion of the use of extracting combs in the outside of supers is certainly a move in the right direction.

* * *

I was much interested in reading P. F. X. Ryan's kindly criticism of Prof. J. H. Lovell's article on flowers, page 654, Oct. 15, until near the close where he asked me to stand up and take my medicine. Humph! I see it does make a difference whose ox is gored. But really, friend Ryan, I believe I used to think exactly as you do, but have come to think somewhat differently in these later years. In fact, I think that the Christ was born, suffered hunger, thirst, and weariness, as we do; that he grew strong by the use of his muscles as we do, and that his mind grew strong by thinking, whether in school or out of school, in the open fields, or studying the social and religious customs of the people among whom he lived, just as our minds grow strong by using them. Of one thing I am sure. He was a wonderful thinker, and he taught those around him to think also, to draw lessons from the birds and flowers and fields. More, he taught them to put first things first, and do as well as to think; and his life may be an inspiration to us in our business as truly as the life of Lincoln or Langstroth. Suppose we draw a lesson from the birds this afternoon. Why does a hen sit on a porcelain egg half the summer? That is easy enough. Because she doesn't think or reason, or she would know she could not hatch a brood of fluffy chicks from porcelain eggs. And why does a man buy an improved frame hive and never open it, but let the bees build the combs crosswise or any way it happens? Or why does he let his bees starve just before the harvest? Why? That seems easy enough too. Because, like a bird, he does not think or reason, or he would conduct his business in a more sensible way.

Beekkeeping in California

P. C. CHADWICK, Redlands, Cal.

Continued from Dec. 1.

After spending a short time at this apiary we rode back to Perris, and then to the northeast to the apiary of E. Gunther. Leaving there we continued until we reached the home of Mr. W. R. Neudorf. Here I found a typical little home lying in a cove made by the abrupt ending of a short canyon—just a few acres, but well protected on all sides by high hills. Oranges, pears, figs, and other fruits were thriving, as well as an apiary of about 200 colonies. Mr. Neudorf had on hand about 20 cases of honey of this season's crop. Here I saw the most complete honey-house I have seen in California. It was a two-story affair with ample room for all purposes. Mr. Neudorf has his bees located on a sloping bench of land above his house, the honey-house being built in the side of the hill—the upper story on a level with the apiary, the lower on a level with other buildings. The honey is wheeled into the upper story, and then extracted, passing through a gravity strainer to an immense tank below. The lower story is concrete throughout, with a concrete base for the honey-tank to rest on at a height just sufficient to admit a 60-lb. can under the faucet. There is also a narrow opening left in the base large enough so that a small oil-stove may be placed under the tank to warm the honey when necessary to make it run freely. Honey can be drawn from the tank at any time as it is entirely enclosed, and is bee and fly proof. I planned to get a picture of this place for GLEANINGS; but owing to extremely cloudy weather I could not.

Here I left Harry for the day. He returned to his home ten miles to the west while I went on through Coyote Pass, and continued for a shorter distance down into the Hemet Valley. I reached the home of my wife's mother about 6 P. M., somewhat tired, after covering 80 miles for the day, but well satisfied with my machine.

The next morning I was up early, and ready for another day's travel. Clouds were hanging far below the summit of Mt. San Jacinto; but "It never rains in California in the summer time." Harry and I were to meet at the Elsinore road at 9 A. M., and visit a number of apiaries on the way down to Elsinore. We met as planned, and were soon at the home of Thos. Chaffin; but no one was at home, so we continued our journey for a few miles. Leaving our machines near the road we walked a mile to the apiary of Mrs. H. R. Youngling, who

is Harry's aunt. Clouds had continued to grow more dense since morning, and it was now beginning to mist and show signs of rain; but "It never rains in the summer in California." By the time we reached our machines it was sprinkling lively, so we journeyed leisurely on down the canyon toward Elsinore, stopping on the way at an apiary owned by a Mr. Farr. We did not tarry long, but began to make haste toward Elsinore; but, alas! we had covered but a short distance when the storm broke in earnest, and a torrential rain began falling. Harry, who was in the lead, took a spill in the creek bed, and I followed quickly. He got a "short" on a cutout switch connecting his engine, and was helpless; but he urged me to go for Elsinore "on the high," saying that he would follow later. I obeyed like a little boy, for water was now running into my shoes. I pulled into the first garage I came to, wet and cold, and waited for Harry, who, in the meantime, had found the source of his trouble. In about twenty minutes he arrived.

Still it rained. We were soaked and chilled, and in sad need of dry clothes. We visited a drygoods store and bought some dry underwear, made our way to the bathhouse, and made the change. Then we went to a restaurant for dinner, which we should have enjoyed immensely save for the fact that the coffee was made with sulphur water, and that the proprietor nearly died with an attack of asthma while we were at the table. Still it rained. For three hours we waited in vain for a clearing sky.

The rain eventually ceased. We were 12 miles from Perris Valley, and Harry was obliged to be home at 6 P. M. The road was there, to be sure, but such a road as it was—mud, mud, mud! We started over the washboard hills back to Perris. How we got there I have never been able fully to understand. I do know this, however. Harry was in the lead all of the time. Worse roads could hardly be imagined for motor cycling. Our machines slipped and skidded, and I was never more tired in my life than when I retired that night. My success as a motorcycle novice in getting over such roads was due largely to the fact that I was riding a very low Excelsior, and my 34 inches of leg length was able to right my machine many a time and prevent a spill.

I spent the night with the Warrs—a pleasant one indeed, and I was much impressed with the practical ideas and devices of both A. T. and his son Harry J.

Conversations with Doolittle

At Borodino, New York.

LIGHT IN BEE-CELLAR, ETC.

"Can bees be wintered in a cellar which is light as well as one which is totally dark?"

"It is generally believed that bees winter best in a perfectly dark cellar; and where the cellar may be either light or dark, choose the dark one. This advice is especially for the novice, or the one just starting in wintering bees in the cellar. But for the experienced apiarist I would say that darkness is not a necessity. Bees have been successfully wintered in the farmer's cellar, where my out-apiary is situated, for over twenty years. In fact, perhaps the bees winter just as well there on an average as here at home in my special bee-cellar where it is so dark that one can not see a piece of perfectly white paper waved within four inches of his eyes. The farmer uses his cellar just the same as he ever did except just the space which the bees occupy. He carries stuff to and from the cellar at any time during the winter. When he is loading his cabbage, potatoes, or any other truck for market, the outside, or what is called the "bulk head" door, is left open for one, two, or three hours as may be required, while the three windows in the cellar walls are left uncovered in winter the same as in summer, so that the family may have light when getting the various things needed for family use. No attention is paid to the light or outside air entering except that I set the hives so that the entrances face the rear wall.

"The bulkhead door spoken of, leading into the cellar, is in the front wall, together with one window; and there is a window in the center of each side wall, but none in the back wall. At first I thought that these windows must be darkened, and that the outside door, if opened up for loading things, must have a blanket hung up in front so that it would keep things as dark as possible, except when passing through the doorway. But the farmer said if that must be required, I would have to winter the bees somewhere else, and so I concluded to try one winter with his using the cellar as he always had done. And that trial has lengthened out to over twenty years. With the hives set close together, with the entrances toward the wall, and as near the rear wall as possible and not have the bottom-boards touch it, the bees are in a sort of semi-darkness; or, in other words, the light does not directly strike them; but from the number dying on the cellar bottom I can see no difference in favor of my

undisturbed, perfectly dark special repository here at home. Another thing, I have never found twenty bees dead about the windows in either wall, which shows that light from these windows does no harm."

"What is the best way to keep the hands clean when working with the bees at times when there is a rush of honey coming in, when it drops from the cells on account of the thinness of the nectar?"

"Wipe the honey off on your pantaloons, of course. Strange that you did not know of this trick. In the infancy of my bee-keeping experience I went to see an old beekeeper of a quarter-century standing in his profession. The time of year was when thin nectar was coming in; and every time he got his hands daubed with this thin honey he would use his trousers for a towel. By the looks, no one would hesitate to say that those trousers would stand alone after he had shed them at night. When I came home I told Mrs. D. that I had found out how to get rid of that disagreeable stickiness I had complained to her about the day before. But she objected to my using this way. So the result was that three or four crocks with water in them were placed at convenient points about the apiary."

"Lastly, are there queen-cells in all well-regulated colonies at all times of the year? I am told to look for queen-cells for indications of swarming; but I find them on the combs in the fall of the year when I am preparing my bees for winter."

"It is supposed by the writers in our bee papers that the readers of these papers have learned at least some of the rudimentary principles of beekeeping by reading one or more of our good bee books which enter into the little details of the pursuit. What you see in the fall on the combs are queen-cups, or embryo queen-cells. These resemble an acorn-cradle or saucer. These are found in every colony after the hives are filled with comb, so far as my experience goes. These cups are not more than one-fourth to three-eighths of an inch deep, and are no sign of swarming. When the bees are preparing for swarming they draw out the edges all around the cradle or add new wax to these edges till you find thin walls half an inch or more deep, at which time an egg is deposited in them by the queen. This is an indication that such a colony intends to swarm unless prevented by the apiarist, or bad weather causing a dearth of nectar. In eight or nine days after the queen lays an egg in these thin-walled queen-cells, the cells are sealed over; and, unless a swarm issues sooner, you may expect the swarm to come out the day after the first queen-cell is sealed."

General Correspondence

MILLER VERSUS MILLER

In Re Virgins' Eggs and Larvæ

BY ARTHUR C. MILLER

So I am a "trouble-maker" according to Dr. Miller (Straws, Nov. 15). Very sorry, doctor, but it isn't my fault. Now listen!

Two to five per cent loss of young queens is about normal, and such loss is partly traceable to toads, spiders, and birds. Anyhow, when not over five per cent are missing, the subject calls for no special notice; but when it goes above five per cent there is something wrong in the system. When it jumps up to forty-seven per cent following the addition of eggs and larvæ to the nuclei from which the queens are mated, it is high time to be taking a look around. And that was your loss, doctor.

You say, "For years it has been considered the proper thing to give young brood to a nucleus with a virgin to make her lay sooner." I don't want my virgins to lay; but, seriously, that quoted sentence gives the clue to the reason for the addition of brood as stated, not always causing the disappearance of the young queen; *i. e.*, she is not a virgin. When she has been there so long that the beekeeper becomes impatient at her not laying, and, to hasten matters, he adds young brood, and then laying occurs soon after, it is a pretty safe guess that the young queen was mated before any brood was added.

My error, doctor, was using the phrase, "almost invariably." That is, perhaps, too strong unless it happily results in stirring others, as it stirred you, to investigate. But deducting from your forty-seven per cent loss the average normal loss of five per cent, we have a loss of forty-two per cent—a loss too high to be tolerated.

You may ask, "If it were due to the addition of eggs and larvæ, why did not the queens disappear from the other nuclei?" To use your own phrase, "I don't know." But I make the following suggestions:

Some of the young queens were perhaps mated, or on their mating flight, or some of the combs added may not have had eggs as well as young larvæ.

Henry Alley, who perhaps raised as many queens in his life as any one has, told me a couple of years before his death that, unless he waited three days after removing a laying queen before running in a virgin, the percentage of young queens "missing" was so great that he could not afford to introduce them before that time had elapsed.

The three days allowed time for all the eggs to hatch.

I said *eggs and young larvæ*, because combs containing only old larvæ and sealed brood may be added without causing the disappearance of the young queens. Not having experimented with comb containing eggs only (for such would be of no help to the nucleus) I can not say what effect they would have.

A strong nucleus does not need strengthening, and a weak one can not properly care for a full sheet of sealed brood; hence it will be found that the experienced beekeeper will select combs containing only a small area of brood, and such combs in the queen-rearing season usually have eggs and larvæ as well as sealed brood. In other words, where young larvæ are present, eggs also are usually present. The presence of eggs and larvæ bespeaks to the bees the presence of a laying queen, and probably it conveys the same information to the virgin, and the normal reaction follows.

Now, if you please, doctor, I will turn my attention to E. R. He is sitting as judge, but I will make him co-defendant.

A man who has to hustle at queen-raising as Mr. Pritchard has to, has not much time for experimenting or keeping careful tabs on all of his operations. E. R. says of him: "Indeed, he makes it a practice to give colonies with virgins young brood." I venture to assert that that treatment is too strong. Treatment of nuclei on that basis is not only unnecessary, but would be so expensive that no queen-breeder could profitably continue it.

Now, doctor, you and Mr. Pritchard and E. R. note this: Some time ago they gave up the baby nuclei in twin mating-boxes, stating that the trouble of maintaining them in normal condition, and the *loss of queens*, was so great that they could not profitably continue them. And baby nuclei have to be frequently strengthened, as you know, and it is usually done (and taught) by adding brood, but *not* "in this locality."

Now, doctor, let us watch them explain, asking them first to make careful experiments on a hundred or so cases.

And if you and E. R. please, I beg to amend my statement from "almost invariably" to this: The addition of eggs and larvæ to the nuclei containing virgins is followed in such a large number of cases by the disappearance of the virgins that the practice should be discouraged.

Providence, R. I., Nov. 26.

[See editorial.]

QUEENLESS COLONIES GATHERING POLLEN

Fermented Comb Honey, and Honey Fed to Bees

BY R. F. HOLTERMANN

On page 705, Nov. 1, appear some items in connection with the above subject. I may not know what I am talking about; but for years this subject of pollen-gathering and queenless colonies has been before me. I have had beekeepers tell me that they knew their colonies were all right because they were all bringing in pollen. If there is any thing in this I should like to be enlightened. I have not yet learned to distinguish queenless colonies by any such method; and, to be quite frank, I never expect to tell a queenless colony in that way. With all the bees I have, and robbing going on at every opportunity in my locality in the fall of the year, I do not examine every colony at that time to make sure it has a laying queen. Next spring, however, unless that spring is an exception to other springs, I expect to find some colonies dead or nearly so, and the evidence of a queenless condition last fall will be pollen-clogged combs, indicating that the bees gathered pollen, and did not have larvæ to feed the pollen to, and that it had, therefore, accumulated in the combs. I find no exception to this. Does this not then prove conclusively that queenless colonies do gather pollen? Of course I do not now refer to a colony so long queenless that the bees are all old and with more than one foot in the grave.

FERMENTED COMB HONEY.

The fermentation of comb honey may result from honey-dew which, before being gathered, had the germs of fermentation in it. I had one experience which I am not anxious to have repeated; and if there are such stores in the brood-chambers, unless the winter is of such a nature that the bees can fly frequently, the bees are likely to contract dysentery.

FEEDING HONEY BACK TO BEES.

In view of the prevalence of foul brood, and since no beekeeper can be absolutely positive that there is no germ of foul brood in his apiary, is it wise to feed honey to bees? I think not. In extracting, the honey from one colony is so mixed with that of many others that it does not take many diseased colonies in an apiary to make all the extracted honey more than dangerous to feed back. I have no personal experience in this direction; but I could name some well-known beekeepers who contaminated almost their entire apiary by feeding back diseased honey when, of course, this

was entirely outside of their expectation and object.

More, the feeding of honey excites bees much more than feeding back syrup, and they are more inclined to rob. Henry Alley, on this latter ground, roundly condemns feeding honey to stimulate nuclei, etc., in queen-rearing. I also venture the opinion that, on account of the added excitement, there will be less of actually ripe stores in the combs when the bees get down to normal from feeding 20 lbs. of stores with honey in them than if they contain sugar syrup, and that with an equal percentage of water in them. Lastly, there are no better winter stores than sugar syrup made from the best granulated sugar and water with a teaspoonful of tartaric acid dissolved in a cupful of water and stirred into the syrup when the latter begins to boil. Why, then, venture honey?

Brantford, Canada.

THE QUALITY OF THE QUEEN

What Assures Success in Beekeeping?

BY MAJOR SHALLARD

If I were asked what assures success in beekeeping I would say the quality of the queen. The queen first, the queen second, the queen third, and every time. Given good queens and bad management, you will get honey; given bad or indifferent queens and good management, you might get honey.

THE HIVES NOT SO IMPORTANT.

In my opinion the shape, make, or condition of the hive, always provided that it is large enough to give the queen and bees sufficient room for breeding and storing, has very little to do with the matter. I have a lot of old unpainted hives in use which have sun-cracked and opened in all directions, and the bees fly out practically anywhere they like. Visitors say, "You need new hives badly."

Well, last season I discarded several hundred of the old fellows, and put in some new painted tight good hives, and the bees in them are not coming on as well this spring as the others in the old ventilated hives. Nearly all of my hives are standing out in the sun, and in summer it is a mighty hot sun. The bees fan at the cracks of the leaky hives, and keep them much cooler than the new hives can be kept. Always remember that all my new hives have tight bottom-boards, as I find them more handy to move about than the loose ones. Going into winter the old leaky hives look bad;

but the first cold snap finds all the leaks closed up tight with propolis.

The spring here is a bad one. We had plenty of rain through the winter, and the first few days of spring opened nice and warm. The bees in the old hives tore down the propolis, and were flying beautifully when suddenly a cold snap came, and I could not help smiling when I saw how quickly the bees fixed all the propolis joints again. Do you see the point? The bees can regulate the ventilation. Mind I am talking about strong colonies. If the bees are weak when going into winter they will require assistance; but with really good queens, and provided you do not strike the Isle-of-Wight disease, or any of his cousins, your bees should not go into winter quarters weak.

Now, what are the objections to leaky hives? The bees fly out at you when at work—that is if they are savage or badly handled. The hives will not stand moving about or else take a lot of packing, and they look unsightly. They are not so easily protected against robbers; but if you have the right breed of queen you need not fear robbers.

The breed of queens comes in again with regard to loose vs. tight bottom-boards. I used the latter up to twelve years ago, then I changed all my hives to the former, and I am now going back to the tight ones again.

The merits claimed for the loose ones were: Easier manipulation; easier to clean; and the hive more easily ventilated. Now, if you have the right kind of queen you will never have a dirty bottom-board; and I think that a colony that will not keep the bottom-board thoroughly clean is no good. My queens are not that good; but they were once, and I am doing my best to get them back to that standard; but I am not having much luck so far.

Now with regard to manipulating. I rarely need to lift the brood-nest and put another under it. Take the Alexander method of increase as an instance. He says, find the queen and put her on one frame of brood in another hive. Well, I don't. I go to the hive, lift all the frames out but one, shake off the bees, fill up the bottom-box with frames of foundation or combs, and put the excluder on. I put the brood into a top box, and put it on over the excluder. Looking up the queen is a lengthy process. My method is not. How would a loose bottom-board help me?

Suppose you find that your queens persist in laying above the brood-nest; then you can change the bottom for the top, and you

can come around later and repeat the process; but you can do a lot better by pinching the queen's head off and getting a better strain; because a good strain of Italians will not lay above the brood-nest. The objection to lifting the brood-nest is that it is full of good worker combs, and the chances are that no other story is *all* worker comb.

To sum up, I say that, with the right kind of queens, the brood-nest need not be interfered with from one year to another.

S. Woodburn, N. S. Wales, Australia.

THE WHITE-FLOWERED GOLDENROD

Solidago Bicolor

BY JAMES S. JOHNSON

This plant is a perennial. It grows from six inches to six feet high. It has from one to twenty hard woody stalks in a bunch. It is known by different names, such as stickweed and farewell weed during the latter part of the summer, but its real name is goldenrod. It is spoken of in the A B C and X Y Z of Bee Culture as being very scarce; but it grows here in abundance. It comes up early in the spring, and grows during the whole season, and begins blooming about the 10th of September, remaining in bloom about two months regardless of the weather conditions. Frost will not kill it. The main stalk begins some distance above the ground to branch out in every direction, and keeps subdividing at every leaf until it comes to a very fine point. Small silverlike flowers are found near the top. The nearest ones to the ground bloom first, and so on up until the topmost one has blossomed.

This plant will grow on any kind of soil, rich or poor, wet or dry, clean or filthy. It grows along country roadsides, in fence-corners, thickets, on stony land that is too rough to cultivate, in meadows and pastures. All of our land seems to be seeded to it. When we fail to plow a piece of land one year, the next season it has a good set of the plants. When it is in full bloom one can not look in any direction without seeing the snowlike flowers.

The seed-receptacles are first filled with a down-like fuzzy substance which is fastened to the very small seed. About the first of November these seeds loosen, and are carried away by some breeze. Many are scattered great distances. Nature has arranged the seeds with this downy fuzz in order that they may be disseminated everywhere.

This plant is not obnoxious. It makes a good early pasture for any domestic ani-

mal. It is as early as red clover, and lasts all summer if not grazed too close. Meadows are mowed before it gets hard, and it makes good hay. It is especially good on land where it is liable to wash. It may be gotten rid of by simply plowing or by being used for grazing purposes.

As a nectar-producing plant its equal is not in this country—not so much on account of the nectar it produces, but coming into bloom so late in the season it causes the bees to breed up, and also supplies winter stores. I sometimes get as much as 50 lbs. of surplus honey from a single colony from this source. A nucleus will also make enough to winter on. It would make you smile to see the golden sheets of honey in my apiary. The honey seems to be good for wintering bees. The honey is of a yellow color, having a good body with a very pleasant flavor. When bees are storing this honey one can detect the odor several rods away.

This plant has not been in this country more than fifteen or twenty years. I can remember well when it came here; but to-day it has a firm hold, and seems to have come to stay.

In the spring of 1911 I had nine colonies of bees—two blacks and seven Italians. The season was good, my bees soon became strong, and I had six swarms. I formed four nuclei. All told, I had fifteen full colonies and four strong nuclei on the first of September. The full colonies had two supers on each one. About Christmas I took one super of honey from each, and left one full super and a full brood-chamber to the bees. Last winter these bees all came through well and were strong in the spring.

On the first day of May, this year, I had my first swarm from fruit-bloom and locust flower. Now, at this point all of these supers had become full of brood, bees, and honey; so I gave each hive another super by lifting the one they had on, and placing the empty one beneath. In a short time these supers were full of honey and brood, while in the mean time they kept swarming until I had saved 37 swarms, and several good swarms had gone to the woods. I then made some increase by the nucleus plan, which made in all 65 full colonies by the middle of July.

The flow of nectar then began to slacken somewhat. Each hive was full of bees, brood, and honey. All of these young colonies were in single-story Danzenbaker hives. They were all rousing colonies; but at this point each bee became a boarder, and by the middle of August 27 colonies had used

up their stores, and were without food. Still these queens kept on laying. I fed these bees until the goldenrod began to yield nectar. To-day all of these colonies have about three frames of honey and about one frame of bees. I should be glad if some one would give a plan for managing such swarms in this locality.

I have had Italian bees for three years. I find that they are more prolific than the blacks. My old hives that had supers of honey left on them are strong in bees.

SOME FACTS ON WINTERING BEES.

I find by experience that several things may figure in successful wintering. To start with, I don't believe that bees ever freeze to death when given proper surroundings. Bees, while clustered, can withstand any amount of cold, other conditions being favorable. I will name some of those conditions:

1. They should be kept dry.
2. They should have an abundance of air.
3. They should have plenty of good stores.

The quantity of bees does not matter so much, but there should be young bees with a young vigorous queen. If a colony is to be kept dry, the hive should be well covered by outside protection from rain, snow, and the like. This can be done in several different ways. A good cheap way for me is to take clapboards about $2\frac{1}{2}$ feet long; nail them to lath at each end; use enough to make a cover about $2\frac{1}{2} \times 2\frac{1}{2}$ ft. square, and lay a brick or stone on top of the hive to give slant to the cover. This will make a good outside cover. Water should never be allowed to fall on the hive, as capillary absorption will take place during snow-melting or rain, and wet the cluster of bees and the packing. This dryness is one of the main essentials.

The amount of air a colony of bees should have is no longer a question with me. In the summer time bees use their wings for this purpose; but bees in their winter nap breathe slowly, like hibernating animals, and need to have plenty of air. Bees should have a larger entrance in winter than in summer. This question ought to have been settled long ago for there has been enough said along this line. I prefer an entrance one inch by 12. This will do, but should be larger.

I want to refer to GLEANINGS for Sept. 1, p. 561. The way Mr. Albin Platz packed his bees seems to be all right to me except that, as he used sealed covers, he should have given his bees a larger entrance. He came very near killing them by suffocation. If air is essential to bees they need all that

nature furnishes. Bees do not need cold, but they need the oxygen that is in cold air. If Mr. Platz will take another hive, like the ones he referred to last winter, and pack as he did, either with sealed covers or absorbents, and give them lots of air, they will winter well. The absorbents he refers to gave his bees more air, hence the better results. A colony of bees with a large entrance, and well protected from outside dampness, will never have any accumulation of moisture on the outside.

Langan, Ky.

LAW ON SELLING HONEY FROM DISEASED APIARY

Feeding Syrup in the Cellar

BY J. D. ROBINSON

1. The Michigan foul-brood law as it stands at present (see Sec. 4 of Article 66 of the Acts of 1901) reads as follows: "If the owner of a diseased apiary, honey, or appliances, shall knowingly or willfully sell, barter, or give away any bees, honey, or appliances, or expose other bees to the danger of said disease * * * said owner shall * * * be liable to a fine of * * * etc." Question. Under such a law what can the beekeepers of Michigan, who have foul brood, do with their honey?

2. This spring we purchased a large number of Danzenbaker supers for plain sections (4 x 5) with fences, etc., complete. Our crop was too small to judge definitely; but from several hundred pounds produced in these sections we anticipate difficulty in getting them full enough to weigh 13½ ounces. Supers would be well filled and capped, but scarcely a section would reach the 13½-ounce mark, and none above that. Now, as the honey in every other respect would fill all the requirements for "Fancy White" under the new Colorado grading rules we should like to ask: (a) What per cent of sections should reach this weight? (b) Is the trouble with the honey (raspberry and clover principally, gathered during dry weather)? (c) Was the trouble possibly with the apparatus or the manipulation? (d) Do others have the same difficulty to complain of?

3. On account of a poor summer and fall flow, some of our colonies had to be fed. The weather turned cool, and much of the syrup fed is not capped. Will this unsealed syrup in the combs spoil? We may say our cellar is dry and well ventilated, which we assume is in favor of keeping stores.

4. In spite of precautions and feeding several colonies, probably a dozen or so

have not to exceed ten or fifteen pounds of stores. Can they be fed syrup in the cellar?

As a note to question one, I might say we are thankful that as yet no foul brood exists in this county.

Pellston, Mich., Nov. 25.

[1. If we are correct, the intent of the law is to prohibit the selling of honey from foul-broody hives to beekeepers to whose bees the disease might be transmitted. We know it has been customary to sell such honey to honey merchants for human consumption, for it is, indeed, as good as any. If such selling is prohibited under the law, it will be difficult to prove violation. If the law does prohibit all selling of honey from infected apiaries it might nearly bankrupt the beekeeper who has 50,000 lbs. of honey to sell. If he boiled it to kill the germs of foul brood he would cut down the selling value of it from a fourth to a third. The reduction in price might represent his actual profit. We do not know of any case in the United States where any beekeeper has been prosecuted for selling honey from an infected apiary to a honey merchant. Any beekeeper to-day who buys any honey to feed his bees is running a great risk unless he knows the exact source of it. Honey that goes into the hands of a commission man or honey merchant is intended for human consumption. If it goes to the baker or confectioner the very process of cocking would render it immune.

2. Sections that do not weigh 13½ ounces would, according to a literal construction of the Colorado grading rules, be barred from the "Fancy" white and No. 1; for these grades clearly call for a section weighing not less than 13½ ounces. A "choice" grade would permit of a 12-ounce section. According to the Eastern rules, the honey described might be sold as "A Fancy." The consignee should then be advised that the grade is according to the Eastern rules. See page 2 of our advertising section. *a.* No section under 13½ ounces is allowed. *b.* The light weight was probably due to a premature shutting-off of the nectar supply. *c.* It may or may not, but probably not. *d.* If the season is fair, no.

3. It is better to have syrup fed early enough to be capped over. In most cases colonies will winter on such syrup, providing, when it is given, it has the consistency of not less than two parts of sugar to one of water. Such unsealed syrup probably will not spoil.

4. We would not advise feeding syrup in the cellar. Give the bees rock candy, or

moist coffee A sugar, such as Mr. A. C. Miller recommends on page 770, Dec. 1.—Ed.]

RIPENING HONEY OUTSIDE THE HIVE

BY I. HOPKINS

We all know how strongly the ripening of honey anywhere but within the hive has been opposed at different times; but to any one who has seriously considered the arguments of its opponents they would have but little value, inasmuch as they have not been based on actual personal experience. I have known of only one beekeeper, and he a New Zealander (Mr. Hobbs), who had tried the system and failed. I do not know any of the particulars of his trial. On the other hand, we have direct evidence from men of integrity who have had long experience in ripening honey outside the hive who favor it in every way—men whose truthfulness their strongest opponents will not doubt; to name only two or three, Moses Quinby and his son-in-law, L. C. Root; E. W. Alexander, and T. W. Cowan. Of the few who attended a meeting of beekeepers at Wellington recently, three had experiences, and advocated ripening honey outside the hive, and a proposition to the contrary by one individual was thrown out. What better evidence could be obtained?

THE SYSTEM NOT NEW.

The ripening of honey outside the hive is by no means new. Part of chapter XI. of "Quinby's New Beekeeping," second edition, 1881, is devoted to it. I have also a paper on the same subject by L. C. Root, read before the New England Beekeepers' Association in 1883, in which he speaks of his 13 years' experience, and states in detail all the advantages to be gained by the system. The following is worthy of note, as it has a bearing on the stock arguments of opponents. He says: "We shall claim, first, as regards the quality of the honey, there is no difference as to the time it is extracted. It may be cured (ripened) equally after as before. The only necessity is that it be cured."

My own commencement on a large scale (ten tons of clover honey) dates back to the season of 1883 and '4, and I have adhered to the system ever since with complete success. The late E. W. Alexander's experience is also very convincing, and I think the testimony of a man of his standing in the bee world may be taken in preference to all theories.

RIPENING HONEY.

Until chemical investigation proves to the contrary, I can only believe that the ripening process, whether performed inside or outside the hive, is the getting rid of the surplus moisture usually found in nectar when first gathered, and which, if retained, would cause fermentation. I hold that the bees have nothing to do with it when ripened within the hives, beyond driving off the moisture as it evaporates from the honey-cells, and capping the latter when the process is complete. I think it quite likely that there is a change going on in the sugars during the course of ripening; and if so I see no reason why the same should not go on under any system. Much has been said by opponents regarding the loss of flavor when honey is ripened outside the hive; but this, I feel certain, is all a myth. I could never detect any difference, neither have I known any one who could. I am aware that Dr. E. F. Phillips, in his valuable paper entitled "The Care of Extracted Honey," has stated that "unripe honeys contain a large proportion of sucrose, or cane sugar, and it is probable that, the longer it remains in the hive, the less sucrose will be found in the honey," and also that "the official honey standard allows of 8 per cent of sucrose in honey." The test of well-ripened honey, therefore, seems to rest a great deal on a small percentage of sucrose content.

In this connection I may quote from the report of Dr. H. W. Wiley (late Chief of Chemical Bureau) on two samples of honey sent by me for analysis to Dr. Phillips. Both samples were portions of crops of honey saved under the system I advocate, in the separate seasons of 1909 and 1910. Extract from Dr. Wiley's report: "Sucrose 0.29 per cent" in one sample, and "0.00 per cent" in the other. Dr. Phillips' remarks on the two samples accompanying the report were: "The water content is very low in both, indicating a well-ripened honey, and the sucrose is extremely low, indicating complete inversion."

THE PROCESS.

The system as originally carried out by me, and which I still follow, is very simple, and similar to that of the late Mr. Alexander and others. Shallow tanks are provided. The dimensions are—length, 6 ft.; width, 4 ft. 6 in.; depth, 1 ft. 10 in. A division runs down the center, and each part holds about 1250 lbs.; or 2500 lbs. in each tank. A honey-gate is fixed in each apartment. With regard to the size of tanks, I would limit only the depth. The other dimensions can be left to the fancy

or convenience of the apiarist. I do not advise a greater depth than 24 inches inside. Mr. Alexander found by experience that his tanks of a depth of 36 inches were too deep, and advised 32 in.; but I prefer the shallower tanks I use as time-savers in the maturing of honey.

When ready for extracting, the full combs are taken from the hives, whether partially capped or uncapped, though I like to see the capping just started on the upper parts; but I am not particular in this respect. The honey runs through three strainers from the extractor by gravitation, each one smaller in the mesh than the one above it. When the extracting is finished a specific-gravity and thermometer test is taken and noted. The extracting-room is well ventilated with sliding ventilators overhead, which can be closed if necessary, and the whole outside house is well sheltered, and gets the sun all day. We have an American stove in the house to heat it if necessary. In a couple of days or so all the fine particles of pollen and wax that went through the strainers have risen to the top and formed a thick scum, which, when skimmed off, leaves the honey clear. It is to facilitate this clearing of the honey, and to hasten the ripening, that I advocate shallow tanks.

A further test is now taken for specific gravity, both on the surface of the honey in the tank and of some drawn off from the lower part. We rarely find any appreciable difference. When we find the specific gravity 1.420 or above, we are satisfied. The honey is fit to put up for market. I am speaking of clover honey, which we raise. It may run up to 1.435 or over—the higher the better. As a rule, in bright warm weather the honey begins to get cloudy in about four days or less, showing signs of granulation. Before running it off for market we mix it thoroughly in the tank with a wooden hoe, and take samples in glass jars to test by times, labeling each sample with date of extracting, and specific gravity. We have some samples from the first extracting, nearly seven years ago; and I have before me now two samples nearly six years old, as good as ever. The specific gravity is registered on the labels 1.420, at a temperature of 60 degrees Fahr.

In warm dry weather the honey ripens very quickly, and takes a little longer in damp weather; but having been successful in all seasons I believe there is practically no risk, providing ordinary care is exercised.

LOCALITY.

"Locality," I often think, is a very convenient word for beekeepers. When one of

them makes an extraordinary success where others have failed, or failed where others have succeeded, they fly to that blessed word "locality," as sufficient to account for all the difference, though in all probability it lies mostly in the difference of management. Though I believe that extreme difference of temperature and rainfall may make some difference in the time that it takes to ripen honey, both within and without the hive, I do not believe, as some assert, that it can be done in the one case and not the other. In this connection I thought it worth while to collect for this article the mean summer temperature and mean rainfall for the different parts of New Zealand, where I have successfully ripened honey outside the hive.

MEAN SUMMER TEMPERATURE, FAHR., IN SHADE.	
Auckland	65.7
Wellington	62.1
Canterbury	60.8
MEAN ANNUAL RAINFALL IN INCHES.	
Auckland, for 58 years...	43.28
Wellington, for 53 years.....	49.91
Canterbury, for 34 years.....	25.34

I think, Mr. Editor, I have now covered all this ground necessary to support my side of the question, but I shall be only too pleased to hear arguments on the other side, provided it is based on experience and their process fully explained.

Before closing I may mention that my reason for bringing the hydrometer into use in testing the specific gravity of honey was to work out some simple scheme by which the average beekeeper might ascertain when his honey was fit to put on the market without risk. I carried out about 150 tests, all of which were with what we could call clover honey, and I concluded with the result given above.

With regard to the advantages of the system I advocate, they are very many; but I must refer my readers to Alexander's writings and L. C. Root's paper for details as this article is already too long. It has been said that I stand alone in this matter in New Zealand; but this is contrary to fact, though that would make no difference to its advantages nor to me.

Auckland, N. Z., Nov. 6.

[We solicited the above article, and are glad to place it before our readers; but at the same time we wish to add a word of caution. As we have mentioned before, there has been a large amount of thin unripe honey thrown on the market—in this country at least. This fact does not prove that honey may not be ripened artificially, but it does show conclusively that the plan of extracting honey from combs not at least two-thirds capped over, and taking no par-

teicular pains to ripen it afterward, is to be deplored. And we wish to say further, that, *in our opinion*, ripening honey artificially is a task for an expert, and one that ordinarily should not be attempted by the average beekeeper. There has been so much unripe honey on the market that we believe it unwise to recommend a cheaper method of producing that *may*, unless great care is used, lower the quality of the product.—Ed.]

BEEKEEPING IN THE SOUTHWEST

Poisoning with Arsenate of Lead

BY L. H. SCHOLL

(Continued from page 791.)

Having had varied experience in cotton spraying and dusting during my position as apiarist and assistant entomologist of this State a number of years ago, I think that serious trouble from the above source can be abated to a great extent. Together with my younger brother, entomologist of the Texas Department of Agriculture, I think we can devise a means by another year that will protect the beekeeper, at least to some extent.

We have found that simply dusting the cotton-plants either with Paris green or London purple does not materially affect the bees. Especially so is this true if the poison is applied by the "sack and pole" method, in which the major portion of the poison drops on the plant and the wide leaves, and very little reaches the nectaries under the bracts of buds and blossoms and the under side of the leaves. At the same time this is the most economical and effective method.

The application of liquid sprays, such as arsenate of lead, requires expensive machinery, heavy hauling of the liquid, and much more labor. While the spray reaches every part of the plants better, which makes it so serious for the bees, this is not necessary, since the poison is needed at the very tops of the plants where the cotton-leaf worms do most damage.

Just what procedure to follow we can not say at the present time; but it seems that, where poisoning becomes necessary, it will be well to educate the people toward dusting their cotton-fields instead of using the more expensive methods of spraying liquid poisons that are disastrous to the beekeepers who may be in the neighborhood. As matters develop, further reports will follow.

New Braunfels, Tex.

[The following letter from our English

correspondent suggests that other causes may account for the death of the bees; but in the above case, at least, the spray used on the cotton-plants seems clearly to blame. See also the statement by R. B. Slease, on next page.—Ed.]

POISONED BEES

Is the Poison Always to Blame for the Trouble?

BY G. W. BULLAMORE

From time to time there appear in GLEANINGS and other journals accounts of heavy losses of bees from the spraying of fruit-blossoms. Although I am quite satisfied that a bee can not drink solutions of sulphate of copper or arsenate of lead with impunity, I do think that this explanation of losses is somewhat overworked. Losses which are similar to these are known to occur when fruit-spraying can not be blamed. In England, spraying with sulphate of copper is sometimes used to check the growth of charlock or wild mustard in cornfields. This action has been freely blamed for some of our heavy losses. Artificial manures, and the dust and fumes from motor cars, have also been mentioned. In the absence of any human agency, Nature is accused. Poisonous nectar and frosted pollen are the agencies which she is supposed to employ.

In an account of the Brazilian bee plague, quoted by Professor Zander, it is stated that some of the beekeepers attribute their losses to nectar gathered from goldenrod. Zander also quotes a letter he received concerning losses in Germany, and in it occurs the following passage: "An old beekeeper thinks that when, in spring, artificial manures containing so much salts are spread on the meadows, there is no more luck. The bees take the salt fluid and perish of it. For four or five years he has had this experience with his best stocks, just like me. Another beekeeper thinks it is an infectious disease in the place."

Heavy losses in New York were attributed by some to the pouring of mineral oil on the marshes in the crusade against mosquitoes; but others preferred to blame the spraying of fruit-trees.

Dzierzon gives the following description of vertigo:

Toward the close of the fruit-bloom, which is a very critical time for bees, Nature appears often to prepare a poison for bees, so that in this district we often find at this time, in the hive and outside, a quantity of bees, mostly young, struggling with death. Whether the bees carry in the poi-

son from the mountain-ash, from the crow-foot, or the apple, which bloom at this time, or whether it is a consequence of some night frosts occurring, has not yet been established.

About fifty years ago English beekeepers were experiencing very heavy losses, and the press of the day contains letters on the subject of poisoned bees. One writer expressed his difficulty in attributing his losses to the malignancy of a neighbor, because he knew of no enemy. In another case the editor suggests that a microscopical identification of the pollen in the baskets of the dying bees might throw some light on the subject.

Berlepsch describes a *disease* of bees which ravaged South Hanover in 1859, and says, "Many hives were one day healthy, the next morning half were dead, and the next day all were dead. The disease appeared in many places about Easter, and in many not till Whitsuntide. It was similar to human cholera, and ravaged whole neighborhoods."

The fact that such losses coincide with the flowering of fruit-trees lends countenance to the view that there is a connection between the spraying and the deaths of the bees. It is, however, difficult to imagine a disease of adult bees in which death following the loss of the power of flight was not the chief symptom. Such a symptom must also arise as the result of bad food, poisoned food, or lack of food, and therefore can have very little diagnostic value.

When a stock loses a large number of adult bees they must either die in the hive, in front of it, or away from it. These differences may be influenced by some factor such as temperature. Yet we find them used to denote three separate troubles, viz., fall honey, paralysis, and spring dwindling. As an alternative explanation we find that fruit-tree spraying is put forward. The latter assertion is seldom accompanied by the evidence that any good analytic chemist could furnish; and until it is usual to obtain such evidence there is grave danger that a serious disease of adult bees will be disseminated by stricken beekeepers who remove the remnants of their apiaries to other localities.

Albury, Herts, England.

EXTREME REPORTS DO HARM

BY R. B. SLEASE

I have noticed what the editor has had to say about taking newspaper reports. Hereafter I think it will also be wise to "use a

little salt" with some reports from beekeepers. I have noticed several very unreasonable reports as to honey crops; also as to the amount of work to take care of bees. Now, out here people generally think a beekeeper has nothing to do but to sit in the shade and sell honey, and that he is just robbing the people by charging 8 1-3 to 15 cents per pound for honey; and it is not much wonder when right in GLEANINGS this year there have been reports of bees making an average per hive of considerably over 100 lbs. of honey in the short space of 10 to 14 days. Then, too, some of our leading beekeepers have made statements to the effect that it takes only two or two and a half hours to take care of a hive of bees a whole year.

Now, such reports as these may be substantiated in a very few places, possibly, but very improbably, and in New Mexico it is impossible. They are misleading, and do the bee business as well as the beekeeper a great injustice. At that rate a man could make a fortune in four or five years, and retire, when in reality he must get up and hustle, and then scarcely more than make a living. I hope in future beekeepers will be a little more careful about such statements; but if they are not, I hope the editors will be.

In answer to H. H. Root's inquiry as to how many beekeepers stack comb-honey supers three high, I will say I use from one to six, but mostly two, three, and four.

Beekeeping is badly demoralized in Pecos Valley, from the heavy loss caused by spraying fruit-trees in bloom last spring.

Roswell, N. Mex., Nov. 6.

WINTER FEEDING AND WINTER FEEDERS

Many Colonies in Danger of Starvation this Winter
Because of the Shortage of Fall Honey

BY OREL L. HERSHISER

There seems to have been almost a complete failure of fall honey throughout the eastern States and eastern Canada for the season just closed. In many of the best buckwheat locations no surplus was secured, and goldenrod and other fall flowers yielded only enough to keep up brood-rearing. As the honey season closed, the bees were found to be badly lacking in the necessary winter stores.

In conversation with numerous beekeepers at the convention of the Ontario Beekeepers' Association at Toronto recently, it was surprising to learn that every one with whom I had talked on the subject had fed heavily. Purchases of sugar by the ton

had been a common occurrence, and one successful beekeeper reported his bill for sugar at about \$600. One expert beekeeper lost several colonies from starvation before he discovered how short of stores they were, and he found it necessary to feed nearly 30 lbs. of syrup to each colony.

Most of the bees that need feeding are fed during the warm weather of fall; but for those who have been so unfortunate as to overlook the matter at an earlier date some simple directions for winter feeding and a description of winter feeders may be helpful.

In some respects, late fall and winter is a better time to feed than earlier in the season. After all breeding has stopped, there is no brood to consume the winter stores; after the bees have settled down for winter no precaution against robbing is necessary; and with no brood in the hives a better estimate of the food required may be made. Moreover, the last food stored will be the first to be consumed by the bees. This last point is especially important in view of the fact that granulated sugar syrup has been found to be superior to the best honey as a winter food for bees. The late fall feeding of granulated sugar syrup places the best of winter stores where they will be consumed during the most trying of the wintering season.

Winter feeding can not be successfully accomplished with any feeder where the bees must move far from the cluster to reach the food. Hence the division-board feeder, or a feeder on the bottom-board, or beneath the hive, or any feeder over the cluster where the bees must traverse a space of several inches to reach the food, will not answer. In cold weather the bees of a strong colony can hardly be induced to go over the edge of a shallow pie-tin to reach the food. The only feeder that answers every requirement for winter use is of the pepper-box-feeder type in which the food is brought right against the cluster. Where it is necessary to feed rapidly and in considerable quantity the ordinary pepper-box feeder is too small; but it is an easy and inexpensive matter to improvise one out of a ten-pound honey-pail or a ten-pound lard-pail which will contain 14 pounds of syrup. All that is necessary to be done is to punch about 100 holes in the lid, each about the size of the lead of a pencil, and evenly distributed over its surface. After the feeding is done the pails may be used for honey, and the only expense of the feeder will be an extra cover—perhaps about two or three cents each.

The feeder, being stocked with the re-

quired amount of syrup, is inverted over the cluster of bees. The feeder should rest on a couple of $\frac{3}{8}$ strips of wood to allow the bees to reach all the holes in the cover of the feeder. It is obvious that the food is brought so near the bees that they scarcely need to break cluster to reach it, and that they store it right where it is available for immediate use. The act of inverting the feeder should be done over the cluster so the escaping drops of syrup will fall on the bees, which will encourage them to commence taking the food. A quilt should cover all portions of the top of the combs and frames. A hole should be made in the quilt directly over the center of the cluster over which the feeder is placed. It is necessary that the feeder rest in a level position. If much out of level, air may find its way through the holes at the highest point and force the syrup out too fast. The syrup should be fed warm. If fed hot, greater care is necessary in leveling the feeder. The bottom-boards of most hives are propolized so they are syrup-tight; and if the hive is tipped back, any syrup that finds its way to the bottom-board will not be wasted, but will be stored by the bees when they become thoroughly roused up by feeding. If the weather is unusually cold when the feeding is done, packing of leaves, chaff, or shavings should be placed over the quilt and over and around the feeder.

Bees may be fed in this manner during their confinement in the cellar as well as out of doors.

The syrup should be made of the best grades of granulated sugar. Use two parts sugar to one part water, by weight. Bring the water to a boil and stir in the sugar, after which bring to a boil again. The addition of a teaspoonful of tartaric acid to fifty pounds* of sugar is said to be effective in preventing granulation. This is very desirable when feeding at any time of the year, and especially when feeding with the pepper-box type of feeder, as granulation would speedily cause the holes in the cover of the feeder to be filled, and render the feeder inoperative.

Fruit-jars may be used for feeders in a manner similar to the feeder above described. Fill the jar with syrup, and secure a piece of cheese-cloth over its mouth by screwing the rim of the jar down over the cloth or by tying the cloth in place with a string. A board of a horizontal dimension that will allow it to be placed within the super or hive body, or in any event over the

* The usual directions call for a teaspoonful of tartaric acid to 20 lbs. of sugar. Perhaps one in 50 is enough.—ED.]

frames of the hive, with a round hole cut therein that will just admit the neck of the jar so that its shoulder will prevent its going further into the hole, is a convenient device to use in feeding with fruit-jars. Several of these holes may be made in the board, and as many jars of syrup be fed at the same time. The board should be raised above the top of the brood-frames by means of cleats on the under side so the cheese-cloth covering of the jars will be separated from the tops of the frames by a space of $\frac{3}{8}$ inch.

It is usually estimated that from 25 to 35 lbs. of stores, depending on the strength of the colony, is an abundance to carry it through from the time bees settle down for winter until they can gather honey in the spring, which is usually not before the middle of May. In winter feeding, some deduction may be made from the total amount of food required for the full wintering season, allowing three or four pounds per month for the time since the consumption of winter stores began. It should be borne in mind that, during the cold weather when breeding is not in progress, bees consume the least stores.

If the above hints are instrumental in saving a few colonies of bees, the writer will be greatly pleased.

Kenmore, N. Y., Dec. 3.

[To this timely article we would add just one word of caution. As a rule, feed in the late afternoon so that the excitement may not cause the bees to fly out when it is too cold.—Ed.]

BEEKEEPING IN JAMAICA

How Bees Fared During Nine Days of Rain

BY F. A. HOOPER.

It may be a little interesting to readers of GLEANINGS to know how bees fared through nine days of torrential rain with a southeasterly wind blowing at the rate of 25 or 30 miles per hour during the whole time it rained.

October went by with very little rain. The rivers were low, and our ponds and tanks were not nearly full enough. I feared another drouth like that which crippled the last honey crop. On Sunday, November 10, there was a grand electrical storm which was seen throughout the island, and the rain came down in torrents. A strong southeasterly wind then set in, bending down the trees in the apiary; and the swaying of the branches knocked several covers off the hives. I then found it necessary to place heavy stones on each hive

to keep the covers from blowing off. On Monday the rain was somewhat heavier, so I thought it best to feed all the colonies in the yard. I then fed over 250 colonies with about 6 lbs. of muscovado sugar to each. I wrapped the sugar in thin paper parcels, then braved the driving rain and wind, and succeeded in getting in a parcel of the sugar. The most difficult task was in taking out two frames from each super to get in the sugar. It took myself and a lad several hours to get through the feeding, all except about a dozen colonies which we were unable to feed, as we were getting cramped from being wet so long. On returning to the honey-house a neighbor advised me to take a "Johnnie Walker" as a precaution against a cold; but as I do not indulge in whisky, a hot cup of our native cocoa answered the purpose.

On Tuesday, the 12th, there was no abating in the rain and wind, and I feared the other three apiaries were being hard hit, so I ventured out and managed to feed two of them, with the exception of about half a dozen colonies in each yard. I will allude to these unfed colonies later.

The fourth apiary, which I look after for my son-in-law, I could not visit until Saturday, the 16th. This apiary is situated near the seacoast, where there are vast tracts of mangrove. This one was not fed, so I lost a good number of colonies. Fortunately the stands in this apiary are two feet six inches high or the bees would have been drowned, for the water was two feet deep in the apiary. I had much trouble in overhauling the bees, standing in water all the time. I found all the colonies dead which were short of honey—about 24 in number. It appears that, when the bees consumed all the honey in the hive, they ate freely of the pollen, which gave them diarrhea, for the bottom-boards were smeared with the pollen, and had an offensive smell. Every bee was dead in those 24 hives, and piled up on the bottom-boards. But in three of the colonies that died I found one solitary bee in each, and that one was the queen.

The weather now getting to be too boisterous to be far away from the home apiary, I made tracks for Clarendon, where the home apiary is situated, taking the 5:15 P. M. train from Old Harbour station. I arrived at 6 P. M. It had not ceased raining in my absence, and the wind was getting stronger. Sunday, the 17th, the wind and rain were just as bad. I glanced at the entrances of all the colonies at the home apiary, and found five had died while I was absent. These were the ones I did not feed.

A NEW WAY OF DEMONSTRATING WITH BEES AT FAIRS

Success in Spite of Misfortune; How One Man has
been Able to Look on the Bright Side, even
though Crippled for Life

BY L. RIEBEL

Just thirty years ago, on the morning of December 15, 1882, I was helping a neighbor move a house. Through a little carelessness on the part of the man who was managing the affair, and having a bad place in the road to get my team across, I slipped, and the building caught my left foot and broke the large bone just above the ankle. I was taken home at once and the doctor called, who visited me every day for over a week. This doctor did not understand his business, however, on account of using too much liquor, as I afterward learned; and my leg, not getting along as

well as it should, had to be amputated on Christmas afternoon. If I had known then what I know now I would not have needed a doctor at all, and that thigh amputation would have been entirely unnecessary. As it was, I have been a cripple all these years, just because of one man's mistake. Doctors generally bury their mistakes, it is said; but it seems that they do not always do so.

About a year after my leg was amputated I placed my order for an artificial limb. The manufacturer of it did not wear one himself, neither did any of his employees; but he had a nice working model with springs and cords; and to hear him tell about it one would think that it only had to be wound up, when it would walk off almost by itself. However, when I got it I was very much disappointed, for I could not use it with any kind of control. It pained me all the time, had no knee action, and

was a dead drag continually. I knew then that I had lost my hard-earned money, and had worse than nothing for it.

I have tried many of the makes of artificial limbs with wooden and leather sockets, but never found any relief. By this time I was becoming skilled in leather-work of all kinds, having taken up the harness business; and as I was a sort of ingenious fellow any way, I commenced over 25 years ago to manufacture a leg of my own that would fill all the requirements. For a year I kept studying and experimenting, and finally hit on the plan of using an air-cushion and other new features until my leg was a complete success.

During my work in the harness-shop I became interested in bees. My father always kept bees in an old-fashioned way, never realizing much out of them, nor giving them the proper

L. Riebel, Chariton, Iowa, with a set of his combs which he uses in his demonstrations at fairs.

A colony of bees in a wooden leg.

care and attention; but I became so interested that I read and studied every thing I could find on bees. I was soon making beekeeping a specialty, along with the manufacture of artificial limbs for others; and I was all the time experimenting and making observations. I had an observatory hive in my work-shop, the bees going in and out through tubes in the wall of the building; and from my work-bench I have watched them building comb, rearing brood, depositing honey, etc. During the last few years I have been giving some attention to the matter of demonstrating beekeeping at fairs; and I conceived the idea of having bees in the hollow part of my artificial leg. The various photographs show how I rig myself up for fairs, and I can tell you that I attract a lot of attention. I also make demonstrations in a wire-cloth cage, and I have a good many different operations that I go through with in order to explain various parts of the business. For instance, I explain how to take a colony out of a tree, get the bees into a hive, etc., so that the whole plan is perfectly clear. I often let the bees sting me on the face all day, and it has practically no effect. I have the

bees on my head, under the hat, in the specially constructed headgear, and then in my artificial leg as shown. I often go about in this way at fairs from six in the morning until nine o'clock in the evening.

Chariton, Ia.

[Mr. Riebel is certainly a genius in more ways than one. He has made such a study of beekeeping that he has published a small book on the subject, "Hints in Bee Culture," which we find is very interesting. We are sure our friend deserves a good deal of credit for forging ahead as he has done for thirty years in spite of so great a handicap.—Ed.]

BEE-VEILS AND BEE-VEILS

BY ARTHUR C. MILLER

A bee-veil is a necessity and a nuisance, only some of them are more so. There are almost as many kinds of bee-veils as there are beekeepers, but often none are to be had when most wanted.

First, there are the kinds made out of sundry yards of white mosquito netting, hung in voluminous folds over a prehistoric

Hiving the swarm in the very novel hive.

straw hat. These are very effective in their way. No self-respecting bee would be seen near one, and no beekeeper can see any thing that he wants to see through one.

Then there are the kinds made of near-black netting, sewed to the rim of a once-was felt hat. Crown and rim form a cone very suggestive of the classical dunce's cap, and one does not wish to meet his best girl when he is arrayed in it. Incidentally, hat and net have a musty, tomb-like odor, and through one's mind there drifts all the stories of the fatalities from stings.

Then there are the dinky little pocket affairs which are too small to go over your hat brim, and which blow softly against the back of your neck, while a few dozen vicious hybrids take the occasion to roost there. Perhaps you have had a few experiences like that, so you buy one of those bird-cages built on to a pretty brass collar, and after you have stretched the net over it you lay it down on a convenient hive top while you light the smoker. When that is well going you hurry into the veil, only to have the brass band, which has been quietly heating up in the sun, raise a lovely red welt on the side of your neck just where it will show nicely above your collar at the reception this evening.

But you will make one of wire cloth, and be rid of all those troubles. After you have dulled your wife's best scissors cutting out the wire, have pricked and scratched yourself with its sharp points, you finally get her to sew it together for you, and to fit into one end a disk of white cloth, and on the other end attach a petticoat to tuck under your collar. There! That is fine! But a glance into the mirror dispels some of the joy, for you look as if you were in a short section of aerated stovepipe. Anyhow, it will keep the bees off. Um, yes, it does, on the off side, but the "nigh side" of it has tipped against your ear, and an alert bee has pierced the lobe, and ear-rings have gone out of fashion for men, except with a few ancient mariners.

Oh! well, make another then. Try a shorter tube, and sew it to the stiff brim of last summer's straw hat. Ah, that is fine. "Is that a swarm 'way up there?" You tip your head back and see—the inside of your straw hat.

Darn a veil, anyhow!

But there are veils and veils, and it is not necessary to make one's self look like a scarecrow or some oger-dispelling monstrosity devised by a superstitious heathen, nor to subject one's self to sundry tortures and annoyances.

Many years ago the writer adopted a type

Bees in wire-cloth hat, neck-tie, and artificial limb.

of veil which was the result of slow evolution, and which has, in its many years of use since, proved itself as satisfactory as any bee veil can; for mere man will never enjoy a veil for a veil's sake. The foundation, which is at the top, is a duck "beach hat," white or brown. Theoretically, white is cooler, but brown—"kahki color"—does not show the dirt so easily. To the rim of this is sewed a strip of wire cloth, and depending from the lower edge of this is an ample skirt of brown cambrie or silesia. This sort of cotton cloth is used in preference to the commoner and more fuzzy kinds, as bees do not catch their toes in it and trip and fall and lose their temper. But the wire cloth part of the hat is really the "whole thing"—at least it may seem so until you try to use some other sort of hat as a foundation, or some other sort of cloth for the skirt.

First, buy your hat—it is better to buy it than to borrow it or steal it, and of course

Arthur C. Miller's bee-veil.

no good beekeeper steals—he leaves that for his bees to do for him. When you go to get the hat, have your hair cut afterward, not before, or else be sure you get one—a hat, not a hair—which is plenty big enough, for duck hats will shrink, particularly after they have been left out in the rain and dew for a season or two. While you are waiting for it to shrink to just the right point, you have a piece of felt, cloth, or folded strip of paper in behind the sweat-band, and later remove this when you get the swelled head or the hat shrinks.

Take the hat home, and also take a strip of wire cloth long enough to go away around the hat-brim and two or three inches more. If your credit at the store is good, get the "bronze" or "copper" wire cloth. It is better than the painted in several ways. When new it glistens and bothers the eye a little, but soon dulls down, especially after you have left it out in the dew a few times.

Having the wire cloth, cut it like this:

The narrow ends are about three inches wide. For a distance of about eight inches in the middle it is eight inches wide. Now

the edges are to be hemmed—that is, have a narrow strip, say a quarter of an inch, folded over and flattened. Preferably the long straight edge should be the selvedge, and not hemmed. To fold the hem readily, clamp the edge between two sticks, as laths, and bend to right angles, then bend the rest of the way with the fingers, and hammer flat. Or, better still, stop in the tin-shop and let the tinsmith do it in his sheet-metal folder.

Now if you want the rest of the work well done, get your wife to do it, unless perhaps your good mother taught you how to use a sewing-machine.

To the bottom edge of the wire cloth—that with the double slope—sew an amply full and long skirt of brown cambric, letting its folded edge cover the points of the turned-over part of the wire cloth. A double row of stitching, one above and one below the points, and having this on the inside when it is attached to the hat, will give a neat appearance and a smooth finish.

To attach the wire to the hat is easy if begun properly. Start in the middle of the straight edge, and put this spot at the middle of the front of the hat-brim. Stitch around to one end, then go back to the middle and stitch around to the other. The ends will lap a little, and fastening these down is more easily done by hand.

Use the stiffest needle possible, and for thread use strong linen or silk, and preferably use a double row of stitching.

A hat thus made sits comfortably on the head, stays in place, permits freedom of movement, and allows a free circulation of air. Made as described, it is durable and looks as well as such things can.

But—you will have a more pleasant time if you keep decent, good-natured bees, and dispense with a veil altogether, or almost.

Providence, R. I.

THE SPOKANE INTERSTATE FAIR

I am sending you two photographs of exhibits, and a list of awards in the apiary section at the Spokane Interstate Fair.

CHESTER L. MYERS, *Publicity Manager.*

CLASS 1.—HONEY.

- Lot 1. Display of comb honey—
 - 1st prize, \$10, Robert Cissna, North Yakima.
 - 2d prize, \$5, Mrs. M. E. Baker, Spokane.
- Lot 2. Display of extracted honey—
 - 1st prize, \$10, Robert Cissna.
 - 2d prize, \$5, J. A. Yeoman, Spokane.
- Lot 3. Specimen of white comb honey—
 - 1st prize, \$5, Robert Cissna.
 - 2d prize, \$2.50, J. P. Kingsland, Spokane.
- Lot 4. Specimen of amber comb honey—
 - 1st prize, \$5, R. Cissna.
 - 2d prize, \$2.50, Mrs. Baker.

One of the honey exhibits in the aparian section of the Spokane Interstate Fair.

Another exhibit in another part of the section.

- Lot 5. Exhibit of comb honey in an extracting-frame—
 1st prize, \$5, R. Cissna.
 2d prize, \$2.50, J. P. Kingsland.
- Lot 6. Specimen of extracted honey—
 1st prize, \$5, J. A. Yeoman.
 2d prize, \$2.50, R. Cissna.
- Lot 7. Specimen of beeswax (10 lbs. or more)—
 1st prize, \$5, R. Cissna.
 2d prize, \$2.50, J. P. Kingsland.
- Lot 8. Design in beeswax—
 1st prize, \$5, Mrs. F. T. Dodge, Kiesling.
 2d prize, \$2.50, Miss Fanny Breik, Spokane.
- CLASS 2.—BEES.
- Lot 9. Single-comb nucleus golden Italian bees—
 1st prize, \$8, J. P. Kingsland.
 2d prize, \$4, Mrs. Bolser.
- Lot 10. Single-comb nucleus dark Italian bees—
 1st prize, \$8, J. P. Kingsland.
 2d prize, \$4, R. Cissna.
- Lot 11. Single-comb nucleus black bees—
 1st prize, \$8, J. P. Kingsland.
 2d prize, \$4, Mrs. Baker.
- Lot 12. Single-comb nucleus Carniolan bees—
 1st prize, \$8, J. P. Kingsland.
 2d prize, \$4, Mrs. Baker.
- Lot 13. Single-comb nucleus Caucasian bees—
 1st prize, \$8, Mrs. Baker.
 2d prize, \$4, J. P. Kingsland.
- Lot 14.—Greatest variety bees displayed in single-comb nuclei—
 1st prize, \$10, J. P. Kingsland.
 2d prize, \$5, Mrs. Baker.
- Lot 15. Most attractive display of bees in observation hive—
 1st prize, \$10, J. P. Kingsland.
 2d prize, \$5, Mrs. Baker.

SPECIAL PREMIUMS.

- Most instructive exhibit—one select tested Italian queen, Root's Red-clover strain, value \$4.00, J. P. Kingsland.
- Winner of class 3, lot 1, 250 Root's "A" grade section honey-boxes, Robt. Cissna.
- Winner of class 1, lot 2, 100 Root's self-spacing brood-frames, value \$3.00, Robt. Cissna.

Winner of class 2, lot 14, one pound each of Root's comb foundation, value \$2.50, J. P. Kingsland.

Winner of class 1, lot 3, copy "Advanced Bee Culture" for expert beekeepers, published by A. I. Root Co., value \$1.00, Robt. Cissna.

Winner of class 1, lot 7, copy "A B C of Bee Culture," leading text book on beekeeping, 576 pages, and several hundred illustrations; value, \$1.50, Robt. Cissna.

Winner of class 1, lot 6, one standard Root bee-smoker, value 85 cts., J. A. Yeoman.

Winner of class 1, lot 5, *Gleanings in Bee Culture*, full year's subscription, \$1.00, Robt. Cissna.

Best exhibit by lady beekeeper, copy "How to Keep Bees," by Anna Botsford Comstock, value \$1.00, Mrs. Baker.

EXPERIENCES OF A FOUL-BROOD INSPECTOR

Some Unusual Locations for Apiaries

BY J. E. CRANE

Continued from page 766, Dec. 1.

I wish I had kept track of the number of different styles of hives I have found in my work. Some were large, holding two or three bushels, and some small; some with large entrances, some with small; some with porticos, and others without; some with frames, many without. It had been so long since I had seen bees in box hives that I did not know that any one used them; but after finding large yards with no other kinds I began to think I didn't know all about beekeeping, especially when I found the bees in box hives in decidedly better condition as a rule, in the spring, than those in frame hives. One man asked me

in regard to changing from box to frame or patent hives, as he called them. "Don't, don't," I said, "unless you are going to use the frames, for of what earthly use are frames in a hive unless they are used by the beekeeper? They cost more, and are not as good. Of course, if you use them they can be made of great value, and for the suppression of disease they are useful."

I found one yard full of great clumsy box hives, made of coarse lumber, but every hive was blessed with a portico, Langstroth style, tacked to the front of it. The idea seemed to be that bees, in order to do well, must have a nice place to lounge, just as a man, to be quite happy, must be able to sit on a hotel piazza and smoke.

I find that many beekeepers fail to get much surplus because of lack of a large enough passageway from the brood-chamber into the supers. I remember seeing one hive with one small hole from the brood-box into each box placed on top. Unless bees have a larger opening it is almost impossible to ventilate such a receptacle or to allow the bees to pass through freely enough to store much honey. Such beekeepers are "right smart backward in getting ahead," as some one has said.

I have found some apiaries located near the house, others down in the meadow ten

or fifteen rods away; sometimes in bushes, or among weeds so thick I had to hunt for the hives. In one yard we had to climb through a hen-house window in order to reach some of the hives. Some are on beautiful lawns, in gardens, or orchards, and others on side hills. One such was so steep that I fell three or four times in trying to get up to it, and had to get behind the hives to keep from falling off. I was rewarded, however, for I found a new style of honey-box I had never seen before. Two quart fruit-boxes were tied together, a hole cut in the bottom of one and then placed over a corresponding hole over the brood-chamber. The proprietor said they worked well. I did not dispute him, for I had never tried them.

Another apiary was located on a side hill less steep, and was very pretty. The owner, in addition to being a beekeeper, was a taxidermist. A room in his home was as good as a museum, containing a large number of species of birds and animals. I was especially interested in a crow that was of a light chestnut color instead of black. As I was looking around I turned suddenly, and for the first time saw a large bear, looking so lifelike that I started away from him as though he was about to hug me.

Combs having the diseased portion cut out. See article by E. D. Townsend in the last issue, page 760.

Surplus compartment for honey, made of berry-boxes

Some hotels are not all they ought to be; but I suspect that, as a rule, they are conducted as well as some apiaries I know of. Still, there are some hotels run in connection with a liquor-saloon that are "away off," and I should like to give them a little piece of my mind. The proprietor of one asked me, as he showed me to my room, how I was pleased with his house. I could not help telling him that it would have suited me better if there had been less profanity.

In another town there was only one hotel, and this was little better than the covering for a saloon, and well-nigh bare of furniture. I left my bag, and went down street to see if I could find a restaurant where I could get a light supper, but was informed there was no restaurant in the town. I protested in one of the stores against such a hotel in a town of that size, but was told they served splendid meals.

I had noticed some people gathering near a church, and went over there and found that a church supper was being served by well-dressed people. I had a sumptuous supper for a very moderate price. During the night my bed came near falling to pieces; but I got a fair night's rest, and was ready in the morning for that splendid meal I had been assured of at the store. Breakfast was announced; and after waiting some time at a table a rather coarse young man came to me with some kind of cereal, and blurted out, "Do you ever eat such stuff as this?" The rest of the meal was after the same style.

WRITING ARTICLES FOR LOCAL PAPERS.

I have found it helpful to give a few facts to the local press, where there is a lack of interest on the part of beekeepers regarding foul brood, for it has seemed almost useless to try to control this disease unless the inspector has the hearty co-operation of the beekeepers themselves. Most country editors, and even city editors, are glad to get such items. I have also had a lot of red cards printed with these words: "Contagious Disease! It is unlawful to sell or give away the contents of this hive."

A CASE WHERE THE DISEASE DID NOT SPREAD.

In a former article I spoke of centers of infection of foul brood. One such has puzzled me somewhat. In a city of about 20,000 population, where in one yard this disease was found last year, I did not find a single colony alive; but instead I was told by the superintendent that the moths had destroyed them all. I have looked over all the yards of bees near this one, and have failed to find a trace of disease. It would seem that the disease broke out in this yard and ran its course without spreading, and died where it began. "How did it start?" I have asked myself many times, and have decided that bottled honey was bought by grocers from our larger cities (such honey containing the germs of foul brood). Some of this honey was in turn bought from a grocer, and all that could readily be removed was consumed, after which a bottle without being washed was thrown upon the dump, and a single bee might have gathered enough at a single load to start a colony on the road to ruin.

In another center of foul brood, where it was abundant a few years ago, I found it had entirely disappeared, and farmers were keeping bees without trouble. But I said to myself, "If I throw a stone into a pond

C. A. McCarty's ducks, Walla Walla, Wash.

of water the ripples will keep going till they reach the shore." I traveled to the south without finding any thing, and then to the west for several miles without success; but when rounding a high mountain I came upon it.

Middlebury, Vt.

To be continued.

FEEDING DAMPENED LOAF SUGAR

If a colony of bees is light in stores and likely to starve, would it do any good to place a pile of loaf sugar on the frames over the cluster, and cover with quilt?

Gate City, Va., Nov. 29.

H. P. GROGAN.

[Mr. Alexander fed loaf sugar in large quantities, and with very good results. His plan was as follows: "Make some rims two inches deep, and the size of your hive on top; then take off whatever covering you have over the tops of the frames of the comb, and put on one of these rims. Fill this rim with cut-loaf sugar, the kind that is in cubes about one inch square. Moisten this sugar by sprinkling a very little warm water on it; then cover the sugar with cloth mats so as to retain all the heat from the bees below you can, and the bees will soon come up into this rim of sugar, every one that can, and cluster in it and eat it as they require until spring. I have fed a good many colonies in this way, and never lost one. They usually come through the winter in fine condition, even though they had only two or three pounds of honey in their hives in the fall. One winter I fed two barrels of sugar in this way with good results."

For some reason or other there has been some difficulty connected with the use of this loaf sugar by other beekeepers—perhaps because it was not sufficiently moistened, or possibly because it was not placed in a two-inch rim as advised by Mr. Alexander. Making the hard candy with granulated sugar is not at all difficult after the knack has once been learned; but it is true that considerable care must be used to get it just right. If loaf sugar can take the place of it as recommended by Mr. Alexander it would be a help all around.—Ed.]

BEEKEEPING IN JAMAICA

BY F. A. HOOPER

Continued from page 806.

It appears they ran out of stores and had to resort to pollen, which killed every bee in the hive; for in these there was also the offensive smell, and the bottom-boards smeared with pollen. In one of these five

colonies that died I found the queen alive.

It rained heavily all day, and the strong wind drove the rain into every crack and crevice. The bees ere this had deserted the supers and clustered over the sealed brood; all the unsealed brood was now thrown out; and in colonies which faced the driving wind and rain the bees could not venture to throw the larvæ outside, so they lay on the bottom-boards. The super combs were now getting moldy from the damp, and I feared the worst.

Monday, the 18th, dawned with the same driving rain; but the wind was lighter. It was now blowing from the southwest with great black clouds scurrying across the sky. One could now easily see a change had taken place in the weather during Sunday night. A great hurricane was devastating the western portion of the island, causing absolute destruction to cultivation, and destroying several small towns. The number of unfortunate victims who perished in this disaster was about forty.

On Tuesday, the 19th, the sun shone out brightly. A few bees ventured out of each hive, and, after flying about for a little, they returned to their respective hives. I suppose they soon discovered that there was no work for them to do that day, as every tree was stripped of the flowers they had on.

I then visited the two other apiaries which I fed when the rain set in. In one I found four colonies had died, and one in the other. The bees died of the same complaint, as above mentioned.

On the whole I do not think beekeepers have lost much, except those in the western part of the island. The much-needed rain, although a quarter which fell would have answered, will do a world of good; and the loss of a few colonies of bees will not be felt.

Before closing this article I may say that the broomweed bloomed profusely during the months of September and October. This plant yields an abundance of pollen, but little or no honey; hence the colonies were well stocked with pollen, but with very few stores before the heavy rains set in.

Four Paths, Clarendon, Jamaica, B. W. I.

Duck Eggs in an Incubator

I saw in GLEANINGS for Feb. 15 that you were having trouble with your baby ducks (in the incubator) dying in the shell. My wife manages her ducks this way. She takes her tray out and sprinkles the eggs with warm water on the 14th day, and every day from then on till they hatch. You know an old duck goes to the water every day when she is sitting, and comes back to the nest quite damp. We used a hot-water incubator.

I raised 12,000 lbs. of extracted honey last year from 100 colonies.

Walla Walla, Wash., March 3.

Heads of Grain from Different Fields

Cut-loaf Sugar for Winter Feeding

Our people here have so good a bee-range they scarcely ever have to feed the bees for winter stores, and two winters I found quite a number of colonies nearly starved out, and I fed them with cut-loaf sugar over the brood-nest. Each winter I lost three and four colonies thus fed, but I suppose they were too weak to profit by feeding, as the others pulled through nicely. It is a nice clean way to feed.

This winter our whole yard is weak, and short of stores, owing to a bad season.

Now, I wish to unite weak colonies to get enough bees. Will you please tell me what you think of the feed—your experience, if any, and of the others who may have tried out the plan?

Letohatchee, Ala., Nov. 11. W. N. RANDOLPH.

[Cut-loaf sugar is not as good a feed as lump hard candy—candy that is recommended in the A B C and X Y Z of Bee Culture, under the head of "Candy." Mr. Arthur C. Miller speaks of a new coffee A sugar, which, he says, makes an excellent bee feed given to the bees direct. It has some of the characteristics of brown sugar; is a very pale yellow; and, when squeezed between the fingers, will hold its shape. We have never tried it, but would suppose it would make an excellent feed. We should be afraid that, under some conditions, the cut-loaf sugar would be too dry to make a satisfactory winter food, and we would, therefore, recommend either the candy or the coffee A sugar, referred to by Mr. Miller on page 770, of our Dec. 1st issue.

With regard to uniting, this can usually be practiced after colder weather has set in. When the bees can fly every day and go to the fields it is not practicable to unite. After colder weather sets in, when the bees will be shut in the hives for a week or ten days at a time, they may then be united; but their old location should be changed as much as possible to prevent the bees from going back.—ED.]

Questions on Tiering Up

1. How do we know when the bees are once well started so that we can raise the extracting-super and put under it a comb-honey super?

2. What is a good sign by which to discover the evident decrease of the supply of nectar?

3. Can the sections be called well ripened if left in the super indefinitely with a bee-escape board under it?

4. Is there any danger of moth eggs if sections of comb honey are kept in a case for several weeks?

5. If propolis accumulates in a hive-body, is its cleaning-up urged? If so, how about the bees and frames in it? Isn't it a good plan to clean the hives up during a favorable weather after the close of the honey-flow, if there is plenty of propolis in them?

Chicago Junction, O. LEON P. JONES.

[1. When new honey appears in the extracting-combs and the work of capping the cells has just commenced, it would be proper to place the comb-honey super underneath.

2. You can detect a decrease in the honey-flow by watching the bees themselves; although the most accurate way, if you wish to go to the trouble, is to have a hive on scales.

3. It would depend upon the weather as to whether comb honey would deteriorate over a bee-escape on a hive of bees. During a long rainy spell we should be afraid that the honey would absorb moisture and become somewhat thin.

4. If the comb honey in question had been produced over a colony of black bees there might be some danger of the larvæ of wax-moth. If the colonies were strong and vigorous there would not be as

much danger, although blacks do not protect their hives as well as the Italians.

5. There is little need of propolis except to close up cracks that would let in the cold. When it accumulates to such an extent as to interfere with the handling of frames, or lodges in the hive rabbets, it should be cleaned away.—ED.]

Annual Meeting of Ontario Beekeepers' Association

It was said that the annual convention of the Ontario Beekeepers' Association for 1911 broke all records for attendance; but the 1912 convention, held in Toronto last week, was more largely attended by far than last year. It is reported that 250 beekeepers were in attendance at the various sessions, the crowd at each session being about 125. Papers and discussions were very businesslike and to the point. The following officers were elected for 1913: President, Dennis Nolan, Newton Robinson; First Vice-president, J. L. Byer, Mount Joy; Second Vice-president, Miss Ethel Robson, Ilderton; Secretary-treasurer, Morley Pettit, Ontario Agricultural College, Guelph.

The next event of provincial interest to beekeepers in Ontario is the Apiculture Short Course to be held at the Ontario Agricultural College, Guelph, January 7 to 18, 1913. These two weeks will be filled just as full as possible of practical information for beginners, and advanced beekeepers as well. For particulars and copy of program address

MORLEY PETTIT, Provincial Apiarist, Guelph, Ont.

Sweet Clover for Hay in Kansas

To-day I was shown your pamphlet, "The Truth about Sweet Clover," and read a few of the statements of various ones. This was issued in 1910.

I have been feeding sweet clover to stock for about five years; and my experience has been that it is as good as alfalfa hay. I have read where it contains just a little less protein in it than alfalfa. I find it will not bloat cattle, and that it makes an earlier pasture as well as a later; that it stands dry weather and freezing weather better than alfalfa. It is my experience, too, that it is about the cheapest and best-known fertilizer for worn-out or stale ground.

Two years ago I sowed 130 acres right on the prairie and salt grass without doing another thing, and raised two good crops of hay off from the same last year, and this year I got a crop of hay and thrashed out 900 bushels of seed, for which I am offered \$8.00 per bushel of 60-lbs., white sack thrown in. I am offering the same at \$10.00 in any quantity or for all. I am sowing now 100 acres more, right on the same kind of ground, and will do nothing further than sow it to the ground. I believe it is the coming crop; and where you let it go to seed there will be enough shatter off to keep resowing the field so that it will be perpetual.

Garden City, Kan., Nov. 11. E. G. FINNUF.

Uniform Cage for Mailing Bees Wanted

Referring to the editorial in the October 15th issue concerning shipping bees by parcels post, I will say that some one will surely send bees in a poorly constructed cage that will make trouble later, so that bees will be barred from the mails. This is almost sure to happen unless the right precautions are taken to start with. Why not have a discussion by those who have had experience in mailing bees, and a good strong cage adopted that all must use?

We do not want bees kicked out of the mails, especially those of us who live in this semi-arid district where occasionally we lose every thing from pollen and honey dearth. We want to get better

and cheaper transportation than we have at present. Parcels post will be a great boon to the bee business provided the bees are not barred out because of some fool's mistake.

R. W. WARD.

Uvalde, Tex.

A Very Simple Honey-house Escape

I think that the honey-house bee-escape shown by J. E. Thompson, Oct. 1, page 636, is too complicated. The accompanying sketch shows a very simple arrangement of fastening screen wire to a window, which I am using on my honey-house windows, and which serves the purpose of a bee-escape to perfection. It is so simple that a ten-year-old boy

can fix it. The dotted lines marked A represent boards $\frac{3}{8}$ inch thick by 2 or 3 wide, the two outside ones reaching down to the bottom of, or a little below the window-sash, and the two inside ones extending down to the bottom edge of the top-bar of the casing. All of these strips extend upward anywhere from 6 to 12 inches above the top of the window. Stretch and tack the wire across the window to these strips and to the bottom of the sash, leaving the upper edge of the wire loose, except where it is tacked to the inside strips. Bees inside the house will naturally alight on the screen, and just as naturally climb upward and out of the house through the $\frac{3}{8}$ -inch space between the screen and the side of the house itself, 6 to 12 inches above the top of the window, according to the distance your strips extend above the top of the window. Bees on the outside, trying to get inside, will never find these $\frac{3}{8}$ -inch spaces that far above the top of the window, but will put in all their time right at the top of the window.

I have used this arrangement for years, and never yet have I seen a single bee get in from the outside, while those on the inside crawl right on out without stopping.

B. W. SIMMONS.

Mexia, Texas, Oct. 7.

[Our correspondent makes a good point in that the wire screen should extend 10 or 12 inches above the window-frame itself. One foot is better than six inches, and we are not sure but 18 inches would be better than 12. When robbers get started, and get

on a perfect rampage, they will sometimes go down back through the top of a screen window similar to the one shown in the illustration; and it is, therefore, important to have plenty of space above the window so that the exit for robbers will be high enough above the window so as not to attract the entrance of other robbers.—ED.]

Feeding a Bad Proposition for One Not Prepared for it

In over thirty years of beekeeping I have never had to feed until this fall. I attribute the fact to my having always lived where there was never fall nectar sufficient to be of any profit; and, lest sections be spoiled with the admixture of dark and strong honey, or the colonies store an amount in the brood-chamber insufficient to carry them over winter, my practice has been to remove every section-super the middle of July, when the clover yield is done in the clover belts. Thus my colonies have had all fall nectar for their own use, and ended the seasons heavy with honey for winter stores.

In this locality this year, though clover blooms held much longer than usual, little nectar was gotten from them or fall flowers; robbing is prevalent, and stores are quite short.

I never even owned a feeder until now. I sent for a Miller and some division-board feeders. Every feeder, though painted at the joints, leaked, and ran syrup out of the hive entrance.

I find feeding, if not prepared for, expensive, troublesome, encouraging to robbing, and very uncertain as to results.

T. CHALMERS POTTER.

Doylestown, Pa., Nov. 22.

Where Did the Goldenes Come From?

It is under discussion as to how the golden Italian bees originated—that is, what stock or stocks they were bred from. Please let me know.

Soledad, Cal., Nov. 16.

D. A. PUGH.

[Golden Italians were obtained through selection in breeding; that is, by breeding from the yellowest stock of Italians until the four or five banded bees were obtained. Since the yellowest Italians come from southern Italy, where the bees are known to be crosser than the leather-colored stock from northern Italy and Switzerland, the reason for the fact that the golden Italians are more irritable on the average is plain. Some of the goldenes have some Cyprian or Syrian blood in their makeup. This accounts for the occasional strains that are unusually vicious.—ED.]

The Physiological Effect of Feeding Sugar

This was shown through an analysis recently made of the unsealed and sealed sugar syrup extracted from the winter-nest of a colony.

In the unsealed stores the water contained was 19.5 per cent; in the sealed, 20.2 per cent; and so greater than allowed for honey, and not, as might have been supposed, greater in the unsealed cells.

Invert sugar, 60.9 per cent in unsealed cells; 64.1 in sealed cells. The inversion of the sugar continues, even in the cells. Accordingly the amount of cane sugar sinks from 14.9 per cent in unsealed cells to 11.1 in sealed cells. This abnormally high content of cane sugar betrays that it can not be honey. The nitrogenous content is quite normal, as found in pure honey—.28 per cent in the unsealed and .36 per cent in the sealed. Whence comes this albumen? Not out of the sugar, but the bees have added it out of its own organism. That explains why it is that, after being fed sugar, the bee is so eager for pollen with its rich store of albumen; also

why it becomes rapidly enfeebled upon being fed sugar if there is no substitute for the lacking albumen.

With absolute reliability the proof is consequently brought that bees are weakened—first, through too rapid feeding of large quantities of sugar; second, through feeding during continuously bad weather, or so late that pollen is no longer to be obtained.

It also becomes clear why the finest circle of pollen disappears after sugar is fed, without any brood being started; and why continued feeding of sugar in spring, with a lack of pollen at the same time, so rapidly decimates the colonies, and causes gaps in the surface of the brood. — DR. U. KRAMER, in *Schweizerische Bienenzeitung*.

A Simple Plan of Sifting to Find a Queen

Mr. B. Keep, page 703, November 1, wishes to know if anybody has a simpler plan than his for sifting bees. I think my plan is ahead of his in at least two particulars. In the first place, I do not have to drive nails in my good excluders; and, second, bees run up through an excluder easier than they will run down.

I move my hive off the old stand, put down a new bottom-board, lay a wood-bound excluder on it, then set an empty hive body on the excluder. I take out my frames one at a time, look them over carefully, then shake them in front of the entrance; and, after shaking, put the frames in this empty body. Finally I shake the bees from the bottom-board and old hive body in the same way.

After treating one hive I go to the next; and in thirty or forty minutes after I am through, the bees are all in their hive. Then I lift the hives off the excluders and find the queen on the bottom-board or on the excluder. C. A. MCCARTY.

Freewater, Ore.

[This plan is similar to that mentioned by Robert Forsyth, page 83, Feb. 1, 1912, except that Mr. F. has a special sieve designed to slip in the entrance.

As Mr. McCarty says, bees will go upward through perforated zinc when placed between the entrance and hive proper much more rapidly than they will go down. The reason for this is plain. When they are shaken in front of a hive there will be a regular stampede to get in. When they are shaken into an upper story with a perforated zinc bottom there is no particular desire to go below, and they will often hover together in a large mass, especially if the queen is with them, and it may be some time before they will all go down. For this reason perforated zinc in front of the entrance, or just above the bottom-board, is to be preferred to one placed above the brood-nest.—ED.]

Shipping Cases; Carrier Needed

Mr. Editor, you've been doing a good work by hammering away about carriers and safety cases to keep comb honey from being smashed when shipped. Now suppose you slip in a few words about another thing just as important. You can have carriers and safeties to your heart's content, and your sections will be smashed in them if the comb is not properly fastened in the wood; and to make sure of that fastening, *you must have full sheets of foundation and bottom starters*. A section thus well fastened on four sides will ship more safely in a regular shipping case without carrier than a section fastened only at top in safety and carrier.

Marengo, Ill.

C. C. MILLER.

[We agree to all you say except the last sentence, and there we take issue with you strongly. We do not care how a comb is fastened in a section. If it is placed in any kind of shipping case, and is dropped or handled roughly, especially in cool or cold weather, it will be almost sure to break out, or break enough so as to allow the honey to leak, thus

practically ruining its sale at even a fair price. On the other hand, a comb fastened on three sides of a section only, will usually go through in ordinarily good order *providing the case holding it is put with a lot of other cases into a carrier with a cushion of straw beneath*. A carrier is so big, heavy, and awkward that freight-handlers simply can not throw it. During the last few months we have seen a good many cars of honey unloaded. Not six weeks ago, as fine a lot of comb honey as we ever saw was shipped to Medina in ordinary cases without carriers. The most of this had combs secured to all four sides of the section. It was badly broken down on arrival. If this honey had been put up carefully, and had been loaded, by a beekeeper, on a car bottom, properly braced and cushioned with straw, there would not have been such a breakage and leakage. Or, better still, if it had been put into carriers, not a pound of that honey would have been broken. We hope, however, you will go on preaching the importance of full sheets and bottom starters. We join with anybody or any proposition that, directly or indirectly, will serve to deliver our comb honey to market in better condition.—ED.]

A Start with a Whole Apiary

I am a new recruit in the ranks of the bee profession. In March, 1910, because my health called for more outdoor employment, I violated all the established rules for beginners in bee culture by purchasing a small apiary (34 colonies that came through the spring), together with hives and all other tools and equipment. My experience in modern beekeeping was practically nothing. I purchased the A B C book, subscribed for GLEANINGS, and began to educate myself by reading the writings and experiences of others, and studying and experimenting with the bees themselves. My first season was so pleasant and profitable that I discontinued all my practice, except insurance work, and planned to extend my bee business to "full size." Last summer, with a spring count of 56 colonies, I of course had more honey, though the season here was affected unfavorably by the summer drouth as elsewhere. I now have 93 colonies, good, bad, and indifferent, in winter quarters. I have worked for honey rather than increase.

Pellston, Mich.

J. D. ROBINSON.

Hiving Bees on Leafy Twigs in a Box

J. E. Crane's comments, Sept. 15, p. 597, on hiving a swarm by smoking, is noted. Did you ever try them this way? Take a basket or box to the spot where they are clustered; drop a bunch of leafy twigs in the bottom of the basket or box, then shake the bees on these twigs. It seems to work well. I use a little smoke too.

Spargursville, O., Sept. 25. J. R. COOPER.

[We have never tried the plan recommended by Mr. Crane; but we feel very sure that leafy twigs are more inviting to bees or to a swarm than most other objects.—ED.]

"Denatured" Sugar

Our weather here in this country was so bad that the government allowed beekeepers sugar free from taxes. The sugar, however, at the factory, was mixed with 5 per cent of ground quartz (fine sand) so that it could not be used in the home.

JOS. A. HEBERLY.

Markt Oberdorf, Bavaria, Germany.

Fondant Bee Feed Used Successfully

I wish to state that I tried E. C. Newell's fondant bee feed (page 635, Oct. 1), and fed it in a Doolittle division-board feeder with great success. I fed four colonies 10 lbs. All are in fine condition at present.

JOHN R. DOUGLASS.

San Francisco, Cal., Nov. 6.

Our Homes

A. I. ROOT

Let every one of you in particular so love his wife even as himself; and the wife see that she reverence her husband.—EPI. 5:33.

A little child shall lead them.—ISAIAH 11:6.

During my busy life I have had occasion to listen to many sermons. This is especially true because I never absent myself from church and Sunday-school on the sabbath when it is possible for me to attend. As a matter of course I have listened to many good and powerful sermons, but God's messages have not *always* come from the pulpit. I told you some time back about a sermon that had a tremendous effect on my whole life; in fact, it helped to bring about a turningpoint in my life, and the preacher was a small boy less than six years old. Well, to-day, dear friends, I am going to submit to you a sermon from a girl twelve years of age. Even at that early age she is a child of prayer, and in answer to her prayers God has directed her to send this letter to me. I can not introduce her, because the letter gives only her name as "Little Ella," and no hint as to her parents' name or where she lives.* May God bless the message, and may the Holy Spirit go with it to the readers of GLEANINGS. We have thought best to print the letter just about as we received it, even to the quaint spelling of some words.

Dear Mr. Root:—I am a girl 12 years old and I am going to write to you, as I think God has told me to, asking you to do something for me.

I will tell you my story. My papa is quite well off, and we have an auto, and every thing nice; but he is unkind to mamma, and she is the best dearest mamma ever was, and she is always good to papa—just cries and cries because he is so nouty to her. She works very hard to take care of things around home. Papa just makes her wait on him all the time, and he never lets her go any place with him, and never takes her riding in the auto with him; but he takes lots of other ladies. My papa has got bees, and takes GLEANINGS, and he always reads Mr. Root's piece that has verses out of the Bible and he thinks they are such good thoughts. Now, Mr. Root, if you could write a piece, something about "men orto be good to their wives," I think my papa would read it, and it might help him. I ask God every night to tell me what to do, and I just think of you. So I guess he told me.

* The thought several times came to my mind when deciding to give this letter a place in GLEANINGS that the father, when he sees it, may be displeased with the little girl; but please let him bear in mind that the message may fit a hundred or more different households among our 30,000 subscribers. Even if the child has a mistaken idea in some respects, her message is honest and good. It may be the means of restoring peace and harmony to a thousand homes, through the providence of God. And let me suggest to this good friend of mine who has been reading my writings, that the proper thing to do is to put your arm around the child and thank God he has given her to you, and has chosen her to bear a message of peace and good will to the children of men.

I pray you will not throw this in the waste basket and not pay any attention to it. I will watch GLEANINGS. Papa swears at her, and say offul mean things to her too, and don't ever give her any money.

LITTLE ELLA.

You will note from the above that our young friend had no idea that her letter would be printed; but I have taken the liberty to do so, because I am sure it is more touching, and will reach more hearts, than any thing I could write. Her people are well to do, as you will notice; in fact, they have an automobile. But before taking it for granted that the father is alone to blame, I want to suggest that, inasmuch as it always takes "two to make a bargain," my experience is that it *usually* takes two to get up a quarrel or to stir up ill feeling. The child seems to take it for granted that her mother is in no way at fault for the existing bad state of affairs in that home with its pleasant equipment and surroundings. But I greatly fear, from her frank little story, that the mother too, at least in a measure, is in the wrong. Perhaps she is tempted to give way to complaining and fault-finding. When Satan once gets a hold in a home, it is sometimes very difficult indeed to make him let go. Nothing but the love of Christ can banish the demon and bid him be gone. This good woman should be very patient, and she should be very careful about criticising and finding fault. May be she is like our good friend Martha, as we read in the 10th chapter of Luke—overcareful about things that are comparatively unimportant.

If our young friend has gotten things exactly right, the father is certainly very much at fault; but please notice she tells us that he always reads with great interest "Mr. Root's piece that has verses out of the Bible, and he thinks they are such good thoughts." If this is true, that he loves and admires the verses I have selected out of the Bible, he certainly can not be a *very* bad man. I think it is quite likely—yes, I am almost sure—that this man and wife are, as a rule, good and worthy people. Perhaps one or both are church-members, and yet Satan seems to have gotten a foothold in that home. He is prejudicing the hearts of both of them, and I know by experience that it is often a pretty big job to get him out. Each of the parties will have to take a decided stand and say, "Get thee behind me, Satan." Oh dear me! I know all about it, for I have been through it all; but, thank God, it was years ago. As I go over the past in memory I can not

help recalling the incident where the disciples utterly failed in their attempt to cast out a demon. Jesus told them, as if to encourage them, "This kind can come forth by nothing, but by prayer and fasting." They went to the Master, which is always the right thing to do, and just as this little girl has been praying over the matter of the want of love and gentleness between her father and mother. I suppose Jesus meant by "fasting" that we should be more anxious to have the demon banished than we are to have our daily food. In fact, we should set about banishing evil spirits with such earnest determination that we shall forget even hunger and daily food.

It seems to take a good while and an earnest effort for the average man or woman, or, say, father and mother, to learn that a little thing may start discord. The husband should be exceedingly careful in choosing words when when he feels disposed to find fault, and the same is true with the wife. This is especially true, I think, as we get to be older. Both men and women settle down into fixed habits as they become older, and sometimes these habits of the two parties clash. Now, when you feel like remonstrating or suggesting a change, be very gentle about it. Take the dear wife by the hand as you did fifty years ago. Put your arm about her as a reminder that you two are one. Suppose you want her to let up a little on the housework, and not to be so particular about having every thing "spick and span," and free from dust. Suppose you wish her to attend conference or some religious gathering, and she says she is right in the midst of ironing, and it can not be dropped. If you wish to suggest that spiritual things are of much more moment than the ironing, say it gently and lovingly; and may I suggest to the dear wife, if she finds the good husband is getting to be careless about cleaning his feet or removing his dirty overshoes before coming into the house, she should be very gentle in criticising. Wait until he is not hurried, say some time when he is in a good frame of mind; then tell him how your happiness depends on a neat and tidy dining-room and sitting-room. Suggest to him getting a good substantial foot-scraper to clean the feet; also one of the best modern rugs near the door where he usually comes in. If you go about it the right way, asking God to help you to be gentle and kind, you will surely succeed, and the blessing of the Holy Spirit will follow you.

Now a word about automobiles. I am really afraid they are going to make trou-

ble in more than *one* home and in more than *one way*. Mrs. Root and I have been criticised and laughed at by a certain class because we have never yet owned an automobile that cost a thousand dollars or more, when at least a good many think we *might have* one costing two or three thousand dollars. These high-priced automobiles may bring a kind of happiness for a time; but I feel sure that a great part of them will, in the end, bring sorrow and disappointment. If they are used for taking the whole family to church, well and good; but our last county paper tells of a great drygoods store firm that took all of its employees a dozen miles or more to an outing among some rocky scenery "*on Sunday*." I have feared these automobiles, especially the stylish and expensive ones, might lead to *divorces*. If the good wife who has all her life been in the habit of saving should not care to go on these trips, especially on *Sunday*, it would not be strange if the owner would take some other woman or women who would "jump at the chance" to go.

Our young friend says, "Mama works hard to take care of things around home;" and she also suggests that the father rather expects her to "wait on him all the time." I can readily imagine that the poor woman, in her anxiety to have her household at all times in perfect order, may not herself be always in perfect trim to go out riding like these other ladies mentioned. Perhaps she has waited on him all her life so faithfully that he takes it as a matter of course, and forgets all about it. By the way, I wonder if this little girl's sermon does not hit, first and last, a good many homes, and not only a good many fathers but mothers also. May God in his infinite mercy and loving kindness send the Holy Spirit with this childish message; and may the angel of peace and love, because of it, find an abiding-place in the hearts of many a father and mother.

AVIATION—WHY ARE SO MANY LIVES LOST?

My dear Mr. Root:—I enclose clippings which explain themselves—the one regarding the fairground managers compelling aviators to ascend against their will, and the other on the subject of your talk in the current issue, also confirming my statement.

Lake Roland, Md., Sept. 29. B. B. JONES.

Below is the clipping from the *Baltimore Sun*:

AVIATOR GILL WAS NERVOUS; OBJECTED TO GOING UP IN THE AIR, AS IT WAS GETTING DARK.

CHICAGO, Sept. 20.—"Officials in charge of the aviation meet are all millionaires, and none of them knows the first thing about aviation. They violated every rule to safeguard the lives of the aviators."

William Pickens, manager of aviator Horace

Kearney, so testified at the inquest to-day of Howard W. Gill, of Baltimore, who was killed at the aviation meet at Cicero last Saturday, when his biplane collided in the air with a monoplane driven by George Mestach, a French aviator.

"Gill told me before he went into the air on the day of his death that he was displeased with the way the meet was conducted," said Pickens. "I don't like this idea of flying at twilight," Gill told me.

"Gill was nervous before he started. He went up only after the officials insisted the meet would be a failure if the crowds were disappointed. Mestach is not to blame for the accident. In fact, I don't believe either aviator was."

The testimony of George Mestach, the French aviator, with whose monoplane Gill's biplane collided, resulting in Gill's death, was to the effect that he protested against going up.

"I protested to the Aero Club of Illinois against flying in the approaching darkness," he said, "but they insisted I should fly because the crowd would be disappointed if I did not."

"I consented to go up only after officials had promised that my machine would be the only one in the air," Mestach continued. "They didn't keep their promise. Two biplanes continued to race, and, instead of keeping close to the ground, where they were supposed to remain, they climbed. I was going at terrific speed when I saw one of them about 300 feet ahead of me. I tried to avoid a collision, but it was impossible."

William Burns, of Dayton, Ohio, who served as

Gill's mechanic, testified that Gill had protested that it was too dark to race, and expressed fear that an accident would result with so many machines in the air.

The above condition of things brings to mind the point in Chafin's address in our issue for Nov. 1. The voice of the people, or I might say the voice of the majority, was wrong—*entirely* wrong. That "howling mob," as we might call it, was guilty of murder when it insisted that the aviator should make a flight in spite of his protest. Somewhere out west we had a similar occurrence. A young boy who had not had very much experience in aviation protested that the wind was too violent, and said he could not fly, and *knew* he couldn't, and did not dare to try. Finally, provoked by the unreasonable taunts, he replied as follows: "Well, if you insist on it I will fly, even if it breaks my neck." And it *did* break his neck. If that comes under the head of "local option" I want to say I am *not* in favor of submitting such questions to a crowd of hoodlums, and I never was.

High-pressure Gardening

MY APPLE STORY.

May the Lord be praised for apples! and may he be especially praised for the bountiful crop of apples that he has seen fit to give us this present year. In the Cleveland markets good apples are offered as low as 40 cts. a bushel; and, so far as I can learn, they are plentiful almost everywhere. Probably thousands if not millions of bushels will go to waste because there seems to be no market for them in many places. We hope the new parcels post will open a short cut between producer and consumer, and give the *children*, at least, everywhere an abundance of apples—red, "rosy-cheeked apples"—as well as those of other kinds.

Apples are still my only food for the last meal in the day. Sometimes I do take a little bit of cheese along with my fruit, for I have been all my life in the habit of using cheese with fruit, especially tart fruit.

Now, I have made some important "discoveries" during the past season in regard to apples—at least they are important to me, and I hope they may be helpful to others. When we first moved on to our new premises 32 years ago, for a little time I was too busy to plant fruit-trees. Finally a tree agent came along and said he had been delivering fruit-trees to the farmers, but there were about a dozen trees left. The man who ordered them was so far

away that he could not very well go after him; and he said I might have the lot for a very small price—I think something like ten cents each. Well, we planted them out along where we proposed to have a driveway from the main road to the barn. It took about twelve trees. After they had begun bearing I sent specimens to the Department of Agriculture, and they gave me their names. I wonder if everybody knows that our Department of Agriculture will not only name your apples on receipt of samples, but they will pay all postage. Address the Pomological Department of Agriculture, Washington, D. C.

This row of trees was pretty close to the highway. The two first were Cocklin's Favorite. When the trees began to bear, the apples were so puckery and tasteless that I wondered for quite a time why *anybody* should call them a "favorite." But we soon found out that, after they had become ripe and mellow, they had lost their puckery taste, were full of juice, and had a peculiar delicious flavor, something like a very ripe pineapple. Another reason why we did not appreciate the Cocklin's Favorite was that the two trees were allowed to overbear, and consequently a great part of them were small and gnarly. After two or three years I began to discover what severe pruning will do. Last spring we

paid about \$15.00 to a man for pruning about fifty apple-trees. Well, this pruning made the Cocklin's Favorite larger and fairer than ever before; but notwithstanding the trees were loaded almost to the breaking of the limbs, when the apples began to ripen along in August, as there was no market for early apples, the ground was literally covered with great beauties. We told the neighbors to help themselves. I told our employees, as they passed the trees so near the sidewalk, to help themselves and to get a basket and take some home. Well, it was worth a hundred times what those trees cost to hear the people shout, especially the urchins, as they took a big bite of those luscious apples. Now, do not write me to send you some grafts, for I start for Florida to-day, Nov. 5, and there is no one here on our busy ranch who has the time or takes the interest to cut and pack grafts. Go to any nurseryman and buy trees of Cocklin's Favorite. The next tree in the row was Early Harvest. This ripens considerably earlier than Cocklin's Favorite. But you know all about it, so I do not need to describe it.

The next tree proved to be Rawle's Genet, sometimes called "Genet" for short. This is the latest-ripening apple of which I have any knowledge. They do not even color up much before Thanksgiving time in our locality. They are hard as a rock, and keep so until spring, and with a little trouble you can have them the Fourth of July.

Now, perhaps I had better mention right here one of my discoveries. When you have an apple-tree, early, medium, or late, if you wish to prolong the season and have fine fruit for a long while, begin to gather a part of the apples as soon as they commence to show color or come anywhere near maturity. Keep these first-gathered apples, unfit to eat at the time, in the coolest place you can find—a cool cellar on the north side of the house—and you will find they will be a long time in ripening—a much longer time than if left on the tree; and the important point is that those remaining on the tree will develop larger and much finer fruit because they have more room and more sunshine. Apple-trees usually, especially where the trees are unpruned, set more fruit than they can mature properly. This year we went over the trees and picked off about half the fruit—that which was colored up most—and left the remaining half for two or three weeks. Unless you have tried it you will be astonished to see how this sort of thinning helps the remaining apples. Our winter apples

were mostly picked before the leaves had fallen, as we had no killing frost before Nov. 1. Well, with the trees covered with leaves it is almost impossible for the average man or boy to get *all* of them; and I have greatly enjoyed, during the past month, going around under our apple-trees, especially after a blow or storm, and picking up the great beauties that were missed at picking-time; and they are not only great beauties, but they are finer in flavor, and more luscious, than any apples I ever ate before. The point is, after we had gathered the fruit these few remaining specimens hidden by the leaves had the benefit of the entire vigor of the great strong tree. I suppose there was more vigor this year than usual away along late in October, because the great mass of foliage was bright and green and unharmed by frost. We gathered about half of Rawle's Genet the last of October. The remaining half will stay on the trees until Thanksgiving, or perhaps till toward Christmas. This Genet apple is so hard that frost does not seem to affect it—at least while hanging on the tree. The next tree in the row proved to be a Maiden's Blush, and probably you know all about this. Then comes the Northern Spy, the great standard winter apple for eating and cooking. Then comes a tree of the Fallawater, that a great many people make fun of, but which, when properly developed by pruning and other care, are, I think, along in the spring just luscious. And they grow so large that one big apple makes a good "supper."

Now, after purchasing and setting out the above trees I happened to visit our State fair; and when there I got to talking with an apple-man who wanted some bees. I traded him bees enough for a hundred apple-trees. I can not tell you about the whole hundred trees, but I am going to speak of three of them in particular in that lot. They are the Gravenstein that is just now making such a sensation, not only in the great apple regions of Colorado and Oregon, but wherever these apples are shipped. I suppose you know our pomologists have graded apples according to quality. No. 1 is the poorest and No. 10 is the best. I think the Ben Davis has the honor(?) of being classed as No. 1; but some of the Ben Davis apples raised down in Missouri, "the land of the big red apple," are greedily taken at a nickel apiece along in the spring down in Florida. Well, while the Ben Davis is classed as the poorest, the Gravenstein *heads* the list for quality. Its one fault is that, in our region, it

is a fall apple. We began eating them in August—I think the last of that month; and while disposing of our apples before going to Florida we had two bushels of beautiful Gravensteins as late as Nov. 1; and my second discovery is to tell you how I managed to prolong the season of this exceedingly luscious apple. When they first began to show signs of ripening I picked those that began to show color, and put them in a cool place, as I have explained. Then we kept on picking them in this way. Of course, the five families (each one of our five children has children of their own, one or more), were clamoring for these Gravensteins; and I suspect that some of them thought "grandpa" was getting to be penurious in his old age because he doled them out only soft apples, or those that had just commenced to spoil. In fact, Mrs. Root said, with a little sarcasm, that my great discovery consisted in having only rotten apples to eat all the while, while the common way was to pick out the best and throw away the rotten ones. Now, before I had reduced the matter to a "science" perhaps this was somewhat true; but I have just discovered recently that neither the Gravenstein nor any other apple commences to decay without showing symptoms, even before a rotten spot is visible. If you sort over the apples you have on hand, say twice a week, and press them gently, you will find that the one that is getting ready to spoil will first become mellow, especially on the spot where the rot starts. After a little practice your fingers will become sensitive to these spots, and they will almost automatically pick them out. Now, use these apples thus picked out, at once, or give them to your neighbors to use. In fact, any apple is at its *very best*, just *before* decay becomes visible. You may say this is lots of trouble. But I love apples so much that I just enjoy it. When I am tired of my work in the office, the thought of going out in the cool air and into the apple-shed, and "sorting apples," makes me feel like a boy again.

Now, there is another science in making such work pleasant and handy. Have enough potato-boxes to contain all of your apples. Turn two empty ones upside down. Now set a crate of apples on one empty box and an empty crate on the other. Put them side by side, and they are just high enough so an old man like myself can work without stooping over very much. Take two apples in each hand. If small, you can take three in each hand. Lift them from the full crate into the empty one. You want to get a strong light and good

spectacles, and then by the aid of the fingers and eyes you can very quickly pick out all the apples that are going to spoil, and put them in a little basket near by.

This year our Northern Spy apples have not kept nearly as well as usual. As they are winter apples I did not go over them at all until they had stood perhaps two or three weeks. To my great surprise, out of six bushels I found almost a whole bushel that had begun to rot more or less. Had I sorted them once a week or twice, as I did the fall apples, nearly all of them could have been saved. It has been urged that an apple partly rotten is unwholesome and unsanitary. That may be true; but a great big nice apple with a fourth or less of it spoiled is, in my opinion, just as wholesome as an apple entirely sound—that is, after you have cut out the bad part; and I ought to know, because I have eaten such apples for the past two or three years, and my health just now, thanks to a kind Providence, is just splendid. Some of you may say you would be very glad to have one meal a day of apples if you could afford it; but, dear friend, I think you are making a mistake. If you have three square meals a day, no matter where you are or how you are fixed, these three meals, counting the labor of getting them ready, cost at least ten cents each. Now, ten cents will buy a big lot of apples almost anywhere in the United States. In many places just now you can buy a whole peck for a dime; but I think that, as a rule, take it the year round, a nickel will buy as many apples as you want for a meal—especially if you buy them by the peck or bushel. I do not let a single apple spoil, as I have explained.

By the way, I forgot to mention that this rule I have spoken of will not always tell you about an apple that has commenced to rot at the core; but now here is another trick. Apples that rot at the core generally commence to do so at the stem end; and while you are sorting, put the tip of your fore finger down close to the stem and push it in toward the core. If decay has begun you will find it a little softer at that spot.

I have not mentioned wormy apples, because, thanks to science, it is a disgrace to have wormy apples in your orchard or in your apple-cellar. While you are sorting, if you notice any apples showing indications of being wormy, throw them out to be used first.

There is one other apple I forgot to mention. It is the Paradise Sweet. This, too, is puckery and insipid until along in the

spring; but as it feels soft and looks soft along late in the fall, you may think they are fit to eat, or that they will not keep anyhow; but when the weather becomes real cool they will stop rotting, and with proper care they can be kept clear up into June; and after having thus preserved some fine specimens until May or June I have frequently declared it to be the most luscious apple in the world. When it is real ripe and mellow its insipid sweetness gives place to a most delicious combination of tart and sugar.

Now, if you are getting to be an apple crank like myself I may some time tell you more about apples; for I feel sure that both you and I will live to a greater age by having apples take the place of at least one meal in the day; and not only that, you will keep the use of all your faculties to a greater period than with any other diet.

Now, dear friends, do not imagine from what I have written that it will be all right to eat a big lot of apples *after* you have already had a good hearty supper. It certainly will not work. Every little while, especially when we have a picnic or social, I eat "supper" like other folks, just to see how it will work, and good old Dame Nature makes a kick every time. Perhaps, however, to be more truthful, I should put it this way: My faithful old companion (all my life thus far) gives me the "kick," and says, "Come! wake up, 'old huz.' You are having the nightmare."

SWEET CLOVER AS A COVER CROP FOR APPLE-TREES.

We clip the following from the *Inter-mountain Fruit Journal*:

It would have been a crime some years ago to have any thing but the very cleanest cultivation in the orchard; and the fellow who allowed a spear of any thing green to show was not a good orchardist. Now the fruit-growers have come to realize that no soil is inexhaustible; and when much is being taken out from year to year something must be put back. It was impossible to get commercial fertilizer at a price that would permit its use, and there was too little stable manure available to do any good. Then some one discovered that alfalfa, red clover, cow peas, and even the once detested sweet clover was a most excellent cover crop that could be grown and turned under. This has been practiced almost universally in this section, and the orchards all show the results. Old trees that acted as if they were hide-bound are making excellent growth this year—proving the necessity of fertilization.

If I am correct, the above is exactly in accordance with the teachings of our Ohio Experiment Station. The once detested sweet clover is now gladly welcomed and wanted everywhere. Did you ever?

SWEET CLOVER AND THE DIFFICULTY OF GETTING IT TO GERMINATE THE FIRST YEAR.

The following letter from an experienced man illustrates the matter:

In March, 1911, I sowed 80 pounds of unhulled white-sweet-clover seed on 5 acres, and that spring I got a very poor stand; but I said I would let it go, for there was plenty to seed the ground another year. In the spring of 1912 there were three times as many plants came up as there were in 1911. You remember the spring of 1912 was very wet. I now have a splendid stand of clover on these five acres; part of it bloomed this summer, and part will bloom next summer. This is the reason I am anxious to have my seed hulled this time. I think it will sprout quicker. I want to sow about 1200 lbs. of white seed in the spring.

Brooksville, Ky., Oct. 14.

H. A. JETT.

As our friend suggests in the above, hulled seed is certainly more sure to germinate than that with the hulls on; and a process adopted by our Department of Agriculture, mentioned on page 324, May 15, treating the seeds with sulphuric acid where a prompt and full stand is desired, will very likely be advisable.

FARMING IN FLORIDA; BOTH SIDES OF THE MATTER.

I think you are wrong in printing that advertisement about Florida. I have been there, and know it is the poorest State for farming in the Union. I came near being caught. Thank God. He kept me from "land grafters."

Compton, Cal.

A. H. NASH.

My good friend, if you mean to say that the *whole State of Florida* is a poor place for farming, you are making a big blunder; but if you mean ordinary farming, such as we have here in the North—growing grain, for instance—you may be partly right; but if you were to go down to Manatee Co. just now and see what crops are being grown, and the prices that up-to-date truckmen get for their crops, I think you would be obliged to change your mind about that advertisement by the Seaboard Air Line. There are, without question, places in Florida where the land is very poor and unproductive. Perhaps your visit was made some time ago. Just now expert gardeners are obtaining results in growing potatoes, and other articles of food, that compare favorably with any other spot in the world. May be you had better make us another visit.

THE BOY WHO SMOKES AND HIS CHANCES.

I am sorry I can not tell where the following clipping came from. Does it not about hit the right spot?

The boy who smokes cigarettes need not be anxious about his future, for he has none.—*David Starr Jordan, President Leland Stanford University.*

Index to Gleanings in Bee Culture

Volume XL

In using this index the reader should not fail to note that it is divided into five departments, namely, General Correspondence, Editorials, A. I. Root's writings, Contributors, and illustrations. The index of General Correspondence includes everything except editorials and A. I. Root's writings.
